Friend D., your plan will work tiptop, even if you don't bother the "two other fellows" at all. In fact, it is almost identical with one of my favorite methods, as given in the A B C book. When you get those combs covered with bees, however, look sharp that you don't take the queen. The only safe way is to find the queen before you take this frame of brood and bees.—I think you have hit it exactly in your suggestions as to why the honey tastes different now from what it used to.—I am glad that you and your wife have found a washing-machine that pleases you. We have tried, I do not know how many; but Mrs. Root always votes them "too much machinery;" that is, sooner or later she decides it is more bother to get the thing out, get it ready, then wash it up and put it away than it takes to do the work with a good tub and one of our best stoneware washboards. Your suggestions in regard to the use of wringers would apply, I think, to the use of almost any of them.—I am glad to know that our neighboring town of Tiffin makes churns so good that they get away off to Pennsylvania.—Although I don't believe much in medicines, your Basilicon ointment may be excellent where such a thing is needed. The price is certainly in its favor; but I don't believe it will make a particle of difference with a bee-sting.

HOW TO RAISE CORN.

PROF. COOK GIVES US SOME IMPORTANT SUGGESTIONS IN REGARD TO THE MATTER.

IT may seem a little presumptuous for a bee-journal to take up a subject of such magnitude, especially while there are so many papers devoted to the great staples. Well, there are several reasons why I asked Prof. Cook to give us his ideas on corn culture. In the first place, we are all of us interested in every thing that friend Cook writes, no matter whether it is bees, corn, or kitchens. Friend Terry has given us a book on potato culture that has interested both young and old. I think the following in regard to corn culture will be received much in the same way.

PROF. COOK'S METHOD OF RAISING CORN.

As per your request, I will detail the method that my brother and I use in raising our most important

field crop—our corn. First, we always plow sod ground for corn, and aim to have the same covered with barnyard manure the previous winter—the earlier the better. This is drawn direct from the barn, and evenly spread when drawn. This we think very important. Barnyard manure means good corn, good oats the next year, good wheat the following season, and usually good grass the next two years. We fit our ground in May as fast as we plow. Mr. Terry urges none too emphatically the importance of following the plow closely with the harrow. With our ground in good order—the soil being deep and mellow—we are ready to plant by May 20th. We do not believe we gain any thing by too early planting. Plants, like animals, rarely recover from a serious backset received just at the dawn of life.

We make sure the previous autumn that our best corn is selected for seed, and hung up in a dry warm room. Thus early cured and dried it rarely fails us, even though not fully matured and hardened when husked. Good seed is all-important.

We plant with a seed-drill, plugging up all the holes except the two outside ones. We thus plant four feet apart. It requires about twelve quarts of corn to the acre; but corn is cheap, and we regard it as most desirable that it should be planted thickly, for reasons yet to be stated.

Now let us see what we have gained in this: Instead of working hard all day with a hoe, and planting, say, two acres, or with a hand-planter and seeding three or four acres, we have worked not nearly so hard, and have from twenty to twenty-four acres all planted. We walk in drilling, and space every other row with the eye. With close attention and practice one becomes so skillful that he can row his corn so that the most fastidious would praise it. Soon after the corn comes up we commence to harrow, using a fine slanting-tooth harrow. This takes a wide sweep, and so mellowes the ground and destroys the weeds that the corn is materially hastened in its growth. This harrowing does not cease with the appearance of the corn, but is continued till the latter is three or four inches high.

"But," says one, "what about tearing up the corn?"

Of course, some is torn up; but we planted so generously that there is plenty left. We thus kill the weeds right at the outset, and keep the ground in such fine order that the corn seems fairly to leap into the air. After the corn gets up four or five inches we then put in the wheel cultivator, going astride the rows, and never use a hoe at all. In this way we keep our corn free from weeds, and secure much better crops than of old when we used a hoe to plant and to weed. In this way we get a most excellent yield of this best field crop, with the minimum of labor. In August we sow rye in our cornfield. This makes very fine fall and spring pasture, and is no detriment to our land. Indeed, this crop enriches the soil, as we plow it under in April or May for oats.

If, now, we can cut and bundle our corn with a reaper, and thrash it with a machine, we shall have solved the whole question of raising corn with the least amount of labor.

This coming fall I shall convert about one-third of my corn crop into ensilage. I shall allow the corn to glaze, then cut it and let it lie to dry and wilt for a day or two, then cut it into inch pieces,

and run it into silos which are about 15 feet in each of their three dimensions. In filling I shall work slowly—put in one day, then wait one or two. This gives us excellent feed, and enables us to keep much more stock.

An acre of good corn will give about 15 or 20 tons of ensilage, three tons of which are surely equal to one ton of hay. Fifty pounds of this is a good daily ration. We thus see that, from an acre of corn made into ensilage, we can keep three cows for six months. In this way we can so stock up our farms that it will be easy to get that best fertilizer, barnyard manure, without paying out money, and, at the same time, secure the best returns from our farms. It is just as desirable to make two blades of grass do what one did before, as to cause two to grow where one did before.

A. J. Cook.

Agricultural College, Mich., May 5, 1887.

It is a little singular, friend Cook, that I have been doing almost the same thing you recommend, with corn, peas, and a good many other garden crops. On our clay soil we find more benefit from using phosphate with wheat, rye, oats, and other such grains, and most of our drills are made to sow phosphate with the grain. The best crops of peas we ever had were put in with a drill by stopping up the tubes not needed. The grain-drill does all the marking, furrowing, manuring, dropping the seed, and covering, and does it more perfectly than can be done by hand. So much pleased have I been in putting all kinds of seed in with the grain-drill, that neighbor H. and I have just purchased one of the best grain-drills together. I expect to put our sweet corn in with it this afternoon, May 10th. The smoothing-harrow in place of the cultivator is also my favorite method. With a cultivator it takes a man and a boy and one horse. With two-horse implements we dispense with the expense of the boy (send him off to school, for instance), and do two rows or more at once with simply a man to drive the team. Sweet corn is so uncertain that we put it in thick as we sow, and then chop it out with the hoe when it is beyond danger from cut-worms and other like enemies. Then we have the ground all occupied. The finest stand of spinach I ever saw was put in with the grain-drill; and where farmers have such an implement at hand I believe it would pay to sow all the garden stuff. Perhaps I should say *pretty much* all; for when it comes to lima beans and planting potatoes, the grain-drill will not answer exactly. I would, however, run the grain-drill over the garden spot, charged with phosphate, before planting the garden to any thing. If you want to set out cabbage, celery, or tomato plants, your phosphate is nicely scattered and mixed in with the soil, and your ground is beautifully marked out. In fact, I don't know of a marker that marks any nicer than the grain-drill. For beets, onions, etc., the marks are just about the right distance apart; but if it is too close, take every other mark, or every third or every fourth one. For carrots and parsnips, nothing can fix the ground any nicer. In regard to the economy of labor by your plan, it surely saves time over the old style of planting in hills, as done in the old way.

A REVIEW OF HUTCHINSON'S BOOK.

FRIEND POPPLETON GIVES US SOME THOUGHTS
ON THE PRODUCTION OF COMB HONEY.

ALTHOUGH it may not have been in accordance with the rules of authorship, I announced, in the conclusion of my little book, that "all will find me ever ready to explain and defend my views; or, if necessary, acknowledge my errors." Before "explaining and defending" the one or two points upon which we differ, I wish to heartily thank Mr. Taylor for his kind words, and for the very fair manner in which he reviewed my book. Instead of setting a box over the hive, and completely surrounding and covering the hive with sawdust, Mr. Taylor prefers, as being more convenient, good division-boards and chaff or sawdust in the super. This question of leaving one or two sides of a hive exposed was discussed at one of our conventions at East Saginaw, and quite a number thought that packing upon only three sides of a hive was but little better than none. "A chain is no stronger than its weakest link" was the sentiment expressed. Candidly, I think the comparison is not a fair one, for I do think that a colony protected upon three sides will bear the cold with less danger of loss than will one that has no protection. I think a fairer comparison would be that of leaving two sides of a house without siding or plastering, simply boarded up with one thickness of boards. Although my method of packing may be a little more costly and troublesome, I think the complete protection afforded will amply repay.

I agree with Mr. Taylor, that, as a rule, a queen is at her best during the two first years, and it is possible that it might be profitable to replace them at that age. With small brood-nests, however, the difference between old and young queens is not so noticeable. I doubt the advisability of killing two-year-old queens simply to avoid the construction of what little drone comb will be built as the result of their retention.

It does not seem to me that wooden triangular comb-guides, having their lower edges coated with wax, would possess any advantages, not even that of cheapness, over strips of foundation three or four cells in width; but I must admit, that I have given such guides no trial.

One pigeon-hole in my desk is jammed full of letters containing commendations and criticisms of my little book; and you have little idea how much pleasure it gives me to be able to say that not one of these letters contains any thing that has hurt my feelings, while I have been deeply touched at times to witness the exhibition of tact and kindness in making criticism. Of all these letters, the one that contains the most criticisms is from Mr. O. O. Poppleton, of Florida; but the criticisms are all so fair, and touch upon such important points, that I hope I may be excused for giving it in full. I have the permission of the writer to publish it.

Friend Hutchinson:—A copy of your work on "The Production of Comb Honey" is just received. Many thanks for the courtesy. As I judge your object in sending was to invite a friendly criticism, I proceed to give it briefly.

You start out (pages 9-13) with a very decided plea for spring protection. I am no believer in having a hobby, and for ever hammering at it; but if I ever did have one, it was this of spring protection; and there is nothing in your book which so thoroughly meets my entire approbation as does

this part. As long ago as 1881, at the Lexington Convention, I made the statement that, "in my opinion, chaff hives are worth all their extra cost, both in money and labor, if used for no other purpose than as spring protectives," and I reiterated the same in the essay on chaff hives of the next year's convention. I would no more think of trying to keep bees in the short changeable seasons of Northern Iowa or Michigan, without spring protection, than I would with movable-comb hives. This is one thing on which we fully and thoroughly agree, whether we do on any thing else or not.

On page 12 you say: "The saving of stores in cellar wintering will pay for the expense four times over." Aren't you a little careless or wild in this statement? Compared with unprotected outdoor wintering, you are correct; but, so far as my experience goes, the difference in the consumption of honey, between the cellar and a thoroughly well-packed colony out of doors, is too small to be considered. The only reliable statistics I have ever seen on this subject are those published by A. G. Hill, of the *Guide*. If I remember correctly, those tables cover several years' experiments, with an average of, say, 50 to 75 colonies each year, and the average difference between cellar and outdoor wintering is, I think, not far from one pound only. This agrees with my own experience. This, of course, applies only when hives are properly protected, not when the work is only half done. You also say, on the same page, "It is only by the cellar method that the wintering of bees can ever be reduced to a perfect system." This is certainly too sweeping an assertion for any one to make, for it requires just as perfect a system to successfully winter bees out of doors as in the cellar; and such a system is now in use. I will refer you to A. J. Root for an example, but could refer to others who are practically unknown. I do not think that yourself, or any one else who practices your general system of management, will, as a rule, be successful in outdoor wintering; but that is no proof that others in other localities, and with a different management, can not and do not have just as perfect a system of outdoor wintering as any one has of cellar wintering. While you have failed in outdoor wintering, I know of localities where none have succeeded in any other way.

I also take issue with your views regarding stimulative feeding and spreading of the brood, as given on page 14. I do not think that stimulative feeding can be made of value as far north as your locality is and mine was; at least, I tested it thoroughly and could obtain no advantage from it; but spreading of the brood has been of very great service to me. I attribute a large share of my long-continued success in honey-raising to the fact that I have practiced spreading the brood in connection with spring protection. In fact, the first can be successful only when the latter is practiced. Spreading the brood is undoubtedly much more valuable when one is working for extracted honey than when working for comb honey; and, as your work is devoted to the latter only, I do not, of course, differ so much from you as I should had your opinion covered bee-keeping generally instead of only one branch of it.

I can not agree with you, that separators are not a necessity (page 15). Of course, honey can be and has been raised successfully that could be readily crated, but that isn't all that is needed. Appearance is a prime factor in disposing of comb honey, and in that respect honey produced by the aid of separators has an undoubted advantage.

I prefer neither the one-piece nor the four-piece sections. I find that the two-piece, such as G. B. Lewis manufactures, to have the good but none of the bad points of either of the others.

I have never formed any very decided opinion on the main topic of your little book; i. e., so far as the production of comb honey is concerned; but I take a square and decided issue with you in the advice given on page 25, not to give empty combs in the brood-nest when working for extracted honey. The very conditions you describe as the result of hiving on empty combs are the exact ones we have aimed at trying to attain; viz., to have the bees drop brood-rearing, and attend to honey-gathering during the short sharp flows of honey we are apt to have in the extreme North. This is the point which Mr. Doolittle, myself, and others have insisted on when discussing the superiority of Italians over blacks, but which I judge you have either not noticed or not comprehended. I can simply refer you

to pages 120 and 132, *A. B. J.* for 1886, but it has been much more fully treated in other places.

It is very rare indeed, friend H., that I write to any one as this is to you; but the spirit chanced to move, and its promptings were obeyed. Certainly, no harm can be done, while you may be induced to more fully investigate some of these disputed points before a revision of your work is made.

O. O. POPPLETON.

Hawks' Park, Fla., Apr. 1, 1887.

I see this article is already too long, and I must defer the "explanation and defense" of all these points until next issue. W. Z. HUTCHINSON.

Rogersville, Genesee Co., Mich.

SMALL INVENTIONS.

OUR FRIEND J. A. GREEN GIVES US A FEW VALUABLE SUGGESTIONS.

AS I go about my daily work I am reminded in numerous ways of the debt I owe to my fellow bee-keepers. Many a time a hint given, a method explained, or an improvement suggested by some one in the bee-journals, or at conventions, has been of the greatest service to me. I am not referring to startling theories or revolutionary methods or inventions, but little things that help to smoothe the way and make the lot of the bee-keeper pleasant. A little improvement, into which the author has worked his way so gradually that he does not realize that it is any thing new or particularly valuable, may prove a revolution and a boon to some fellow-worker.

HOW TO MAKE THE SCREEN-DOOR OF A HONEY-HOUSE OPEN BY FOOT-POWER.

I have experienced a great deal of satisfaction this summer in the use of a device which I think would be useful to a great many bee-keepers. Most honey-houses, probably, are provided with screen-doors, closing with springs. If they are not they ought to be. It is unnecessary to mention the advantages of screen-doors, and almost as unnecessary to say that they should close of themselves. A honey-house should be so arranged that it can not be left open for the bees to enter.

GREEN'S DEVICE FOR OPENING SCREEN-DOORS.

In carrying honey or other articles into the honey-house, both hands of the bee-keeper are generally full; and to open an ordinary door he must stop and set something down to get his hands free. This is not only an inconvenience, but it requires some little time, and in the busy season every moment of a bee-keeper's time is valuable. Sometimes, too, his hands are daubed with honey which he does not care to leave on the door-knob as a bait for robbers. All this inconvenience and loss of time is saved by arranging the door so that it can be opened with the foot. I have had such a contrivance on the door of my honey-house this summer, and it has proved a great convenience.

On the top of the outside of your door, nail a piece projecting outward five or six inches. Four or five feet away from the hinge side of the door, nail a board projecting about a foot from the side of the building, and four or five inches higher than the top of the door. In the outer end of this put a small grooved pulley, running horizontally. On the same level, and three feet from the other side of the door, put another grooved pulley, running vertically. A few inches further from the door, and three feet from the ground, put a similar pulley. Now fasten a strong flexible line to the projection on the door, and run it through pulley number one, then back over number two, then down to about two feet from the ground. There fasten it to one end of a light but stiff piece of wood about four feet long. Let the other end of this stick extend back under the door. Bore a hole through this end, and drive a loosely fitting pin through it into the ground. Fasten another piece of line to the free end of the stick; run it over the third pulley and tie a weight to it, heavy enough to raise the stick. Now, by stepping on the stick as you approach the door, the latter is opened; and as you pass through it closes behind you without your being obliged to touch it with your hands, while none of the rigging is in the way or interferes with the ordinary use of the door.

If the door-spring is strong enough, the weight and third pulley may be dispensed with; but with ordinary springs they are necessary to raise the treadle-stick.

AN ADDITION TO THE FOLDING TENT.

Another little convenience I have used this summer is an addition to your folding tent. I was often annoyed by the tent collapsing and blowing over just when I did not want it to. To prevent this I made two light sticks, 53 inches long, and sawed a notch in each end. I then drove a two-inch wire nail into the end on one side of the notch, and bent it over so as to close the notch. One of these sticks was then put at each end of the tent at the bottom, the cord placed in the notch, and the wire nail turned over it, holding it securely. This makes the tent much stiffer and more reliable. When the tent is folded, the sticks can be put inside of it. They add very little to the weight, bulk, or expense of the tent. See Fig. 2.

A SLIGHT DISCREPANCY.

Friend Root, on page 852, last year, at the close of my article, you make the statement that pins, 380 of which cost three cents, are cheaper than $\frac{3}{4}$ -inch wire nails. Your price list says there are 2750 $\frac{3}{4}$ -inch wire nails in a pound. The price is 12 cts. per lb., so that 687 $\frac{1}{2}$ nails may be had for the price of 380 pins, the nails costing scarcely more than half as much as pins. The expense of either, though, for bagging grapes, is insignificant.

Dayton, Ill.

J. A. GREEN.

Friend G., the point you make about the importance of having a door that opens of itself, or, rather, that can be opened by the foot, is an important one. I have, in similar cases, been accustomed to unlatch doors with my foot; but it is a wearying and ungainly thing to do, even if one succeeds. A good many times, the first kick with my toe didn't raise the latch; and sometimes, before I succeeded in getting the door open, I would get red in the face, and come pretty near (?) getting cross. Sometimes I have

managed to release the little finger of my right hand, and get that under the door-latch, and may be in so doing I would drop a comb of honey or push the latch into it. I know what it is to have sticky door-latches and door-knobs, and it always makes me disgusted with myself and things generally. Well, now I want to criticize your machinery a little for opening a door. It is *too much* machinery. I am sure some of our sharp inventors will improve on it right away. Can't some of the devices that have been so frequently figured for operating self-opening gates be brought to bear right here? You see, you have two cords, and three pulleys to be kept from squeaking. I suppose many of you have seen self-opening gates that were operated by fixing a lower hinge at the end of a short arm. Well, now, by making this short arm revolve a quarter of a revolution, the center of gravity is changed so the door swings open of itself, and this same operation raises the latch. The spring to bring the hinge back to its former position would close the door and latch it.

McFADDEN'S LETTER.

SOME SUGGESTIONS ON WINTERING.

I AM sure many of your readers will be interested as I was in the letter of Daniel McFadden. In it there is a whole romance for some one to bring out and color up—not that his statement of the results of “cold storage” is in any way to be questioned. Most assuredly, there is a substantial ground for believing that bees that are kept perfectly quiet consume vastly less honey. Entire darkness, an equable low temperature, and freedom from noise, are evidently the requirements. Here in the Southern-Middle States, where we can winter safely on summer stands, and where bees may fly out every month in the winter, the consumption of honey is often excessive.

Activity involves expenditure among bees, just as it does among the hardy lumbermen in winter, who can eat and digest a quantity of food that would ruin many another less laboriously engaged. Right here we have a case in point. Fourteen colonies in an outlying apiary, and run for extracted honey in 1886, had two full stories, 20 frames (I use the L. frames). I was totally unable to go and extract, and contract them before it became too cold, and they were left with not less than an average of 60 lbs. of stores, some having more. In overhauling them in April, but one colony was found with as much as 5 lbs. of honey, and some were nearly destitute of any honey. But such powerful colonies I never saw so early. No honey had been collected, and very little pollen, for frost had cut the alder and the willow.

In my home apiary of 100 colonies, better protected and shaded, and consequently less active, the consumption was much less, yet by no means so small as many of the records given in cellar wintering.

We are often annoyed by the excessive accumulation of pollen here. This spring, because of the frost just at time of bloom, very little was brought in, and all pollen-laden combs were quickly cleaned out when placed in the hives. J. W. PORTER.

Charlottesville, Va., May 4, 1887.

REBUKING PROFANITY AND OBSCENITY.

THE TESTIMONY OF A BROTHER IN SUCH MATTERS.

BRO. ROOT:—I sincerely sympathize with you in your surprise at the state of morals existing in a neighboring State. While I regret that, while you *hesitated* about rebuking such profanity and obscenity, I have no doubt but that it was the evil one that furnished the apologies for delay. In my own experience for many years, I have always tried to reprove whenever I have heard such talk, on the street, in stores, or at depots, on the spot, and to do it in such a manner as to express how my feelings were pained by such language, and I have as yet never been insulted for so doing; and I believe that, if you had done so on hearing the first expression, you would have succeeded in putting an effectual stop to it for that time. Here let me add my conviction that they, when they perceived that you were listening, continued the discourse, and added to its degrading depravity and blasphemy—it may have been on purpose to torment you. I have heard of just such cases before. There is one command that I think is not sufficiently regarded by Christians nowadays in Lev. 19: 17, and which, if we all tried more implicitly to obey, our heavenly Father would give us the words and right spirit to rebuke sin; then would be verified his promise in Lev. 26: 3-8. May he help us to be “wise as serpents,” is the prayer of yours most truly. A. H. VANDOREN.

Mons, Bedford Co., Va., May 8, 1887.

Thanks, friend V. I, too, have never yet received any abusive language when I have tried to rebuke such things, unless I except one man who excused himself for swearing by saying he supposed this was a “free country.” But I am afraid that Christ's spirit was not in my heart at the time I reprov'd him. Your testimony encourages and strengthens me, and I thank you for the texts you quote.

As it may trouble some of our friends to hunt up their Bibles and find the references I give them here.

Thou shalt not hate thy brother in thine heart; thou shalt in any wise rebuke thy neighbor, and not bear sin because of him.—LEV. 19: 17 (New Revision).

If ye walk in my statutes and keep my commandments, and do them; then I will give you rain in due season, and the land shall yield her increase, and the trees of the field shall yield their fruit. And your threshing shall reach unto the vintage, and the vintage shall reach unto the sowing time: and ye shall eat your bread to the full, and dwell in your land safely. And I will give peace in the land, and ye shall lie down, and none shall make you afraid; and I will rid evil beasts out of the land, neither shall the sword go through your land. And ye shall chase your enemies, and they shall fall before you by the sword. And five of you shall chase a hundred, and a hundred of you shall put ten thousand to flight: and your enemies shall fall before you by the sword.—LEV. 26: 3-8.

There, brothers and sisters, is not that promise strong enough? and I have not a particle of doubt but that it will be fulfilled to the very letter. If we push forward with Christ's spirit in our hearts in this matter of rebuking such talk, verily shall it prove true that five of us shall chase a hundred, and a hundred shall put ten thousand to flight.

HAND-MADE HIVES, ETC.

HOW TO MAKE A SAW-TABLE OUT OF AN OLD SEWING-MACHINE.

FOR the benefit of your A B C class I will give my four-years' experience in making every thing I use in my apiary. Some of these A B C scholars, who doubtless, like myself, have more time than money to spend with bees, and can not afford the expense of a \$25 or \$50 order (including a heavy freight bill) for a small apiary of some 15 or 20 hives, perhaps may be trying to manufacture their own hives, frames, crates, etc., with hand-tools.

For an L. hive I make a plain box of right dimensions, with a rabbet $\frac{3}{4}$ inch cut on the upper inside edge of each end board. I also cut a $\frac{3}{8}$ -inch slot in the lower edge of one of the end boards for an entrance, and nail on a tight bottom-board (which I much prefer). For upper stories I use these same plain boxes without bottom. The end boards can be cut in a miter-box, and have very true and accurate work. I use inch pine boards dressed on the heart side, and nail well. For covers I use a plain board cleated at each end, and laid directly on the hive.

For section crates, I make a plain box (sides of $\frac{1}{2}$ -inch stuff), with a strip of tin nailed on each lower edge of the ends, to support the wide frames one tier of sections high. I make all my frames for brood and extracting purposes from common lath, ripping them through the center. This gives a nearly $\frac{3}{4}$ -inch frame (I use the Heddon reversible frame); and after nailing the end bars to the top and bottom bars with the additional top bar, I find they are very stout and easily manipulated. After once reversing they need no wiring, as I tested by having to move my whole apiary a distance of 25 miles over a rough road the past winter, with only two heavy combs of honey breaking. I will here say, that I much value this reversing system for perfect combs. For nailing frames, the Root wire nails are indispensable. Until the present season I have cut and made all my bee-fixtures with hand tools, such as saw, plane, square, and hammer. I can say to your ambitious A B C youth, you can make all you need, without machinery, even if you have but little knowledge of tools, for I am but a youth, and never handled tools until I began making hives and fixtures for my own use.

A HOME-MADE SAW-MACHINE.

I will speak of a home-made sawing-machine which I rigged up the present season. This will also answer friend Pouders' query on page 215. I have an old cast-away Wheeler & Wilson sewing-machine table, with treadle, given me by a neighbor. To the shaft I adjusted a twenty-inch band-wheel, taken from an old cider-mill. With a \$2.50 Root mandrel, a 6-inch saw, and this machine, I cut all my lath for frames, and make my honey-crates. I am so well pleased with such accurate work I would not part with it on reasonable terms. Tell friend Pouders that, in place of the treadle formerly used, use a stout 4-ft. board with one end on the floor, the other attached to the shaft by means of a strap.

4—W. H. LAWS, 25—37.

Lavaca, Ark., May 2, 1887.

Very good, friend L. The fact that you have used these things successfully is an unanswerable argument, and we heartily commend your energy and industry.

OUR P. BENSON LETTER.

THE SWARM APPEL TREE.

WUZ a maden fare
With golden hair
Whitch sot thare
In the place where—they was a big stone.
She sot onto the stone. Madly the wild winds
tost her flowing lox, while the gentle zeffers softly
fand her peach-blow cheeks. She wuz a chankin
down a appel.

Twus at the witchin our of nit & oll wuz cam. Oll wuz still. Oll wuz sereen. She took anuther bite of the appel and a seed fell out. Softly and thotlessly in the still darkness, mayhap unkonsush of the grate futur before it, the little seed meandered on its wa to the ground. That thair seed groad up into a big appel tree.

THAT APPEL TREE.

Years passed, time went on, & 1 da, it was Joon 10, a swarm cum out. The swarm lit onto that identikile appel tree. The swarm and the appel tree boath belonged to me, whitch I am P. Benson, A. B. S. I spose you noad who I was without my tellin you, but it's no harm to maik sure. Well that swarm was a big 1. It wuz enormuss. I never see sitch a big swarm on enny other tree. That was a Toosday. I woont be sure now, but I think it was a Toosday. I like to tell a thing jist as it is. Well, a Monday next following, a swarm cum out of the same hive and lit onto the same tree. It was a big swarm. I never see a tree have 2 sitch big swarms. Then a Wensday a swarm cum out, also a Thursday. I never see a tree befour git 4 sitch fine swarms onto it: oll from the same hive. A Friday & a Saterdag cum 2 more swarms, makin (6) six swarms whitch that thair tree fetched out from the same hive. The equill of that tree for gettin fine swarms and plenty of them izzent to be found. It haint enny equill.

That fall in the otum of the year we gethered off that tree sixteen—I disremember jist now if it was barrels or bushels, but we woont quori about that, weal call it barrels,—sixteen barrels of as nice appels as you ever sot ize on.

The benefit of sitch a tree is eesy to see. Suppose a man or even a woman or a invalid, starts with 40 hives and gits one of these trees. Eech hive will make 6 swarms and countin the old 1, that makes 7. So if he starts with 40 he will hev

in 1 year.....	280
in 2 year.....	1,960
in 3 year.....	13,720
in 4 year.....	96,040

But mebbe the 4th year wood be extra good, sum yeers is better then uthers, in whitch case instead of 96 thousand it mite be 100 thousand. Weal call it a hundred thousand. Now let him sell these at \$10 apeace & ittlet make a cool million dollars.

The price of seeds of this appel tree is 5 sents eech; 3 for a dime. Cash must accompeny the order, or a draught on Noo York. P. BENSON.

Apiculturalist B. S.

GROWLERY.

THE following comes to us on a postal. As it was written in German, the clerk who opens the mails has translated it. I mention this, because friend S. may claim he did not mean it as rough as it sounds below, but I believe our translator has aimed to put it mildly rather than otherwise.

If you had used me right you would have had \$50.00 worth of trade from me this season. The wax-extractor leaked, and I lost 5 lbs. of wax, and had to have it fixed. You do not care whether your goods come early or late. You could have helped it, if you wanted to, so that my goods would have gone right through. If you have your money that is all you care for. I have lost all confidence in you.

P. SCHONS.

Kellogg, Minn., Apr. 24, 1887.

On reading the above I asked for the previous correspondence, and I can not see that we failed to comply with any request made by friend S., except that he directed us to mark 6000 sections, one smoker, foundation-fastener, wax-extractor, and some wire nails, as perishable. He evidently wanted them marked "perishable," so the railroad companies would hurry them through. I presume the shipping clerks disobeyed orders here, and I certainly should have told them to do so had the matter been referred to me. The above goods can not in any sense be called perishable, and we can not consent to anything that sounds even like untruthfulness, even if we do lose custom thereby. As it is customary to so mark nursery stock, fruits, and vegetables, where they are risked to go by freight, expecting the railroad officials to take extra pains on that account to hurry them through, an extra price has to be paid for this class of freight. Now, some might decide that, if the owner is willing to pay the extra transportation charges, he has a right to mark a box of sections "perishable," if he choose. There may be a difference of opinion in regard to the matter, but I should not want to do it any more than I would want to mark honey as molasses, in order to secure a lower rate of freight. If I can not do business successfully, and mark the contents of a package exactly what it is, then I do not want to do business. Is not this the better way, friend S.?

In regard to the wax-extractor leaking, I can not quite understand the matter. The wax is expected to run right out of any wax-extractor, just as fast as it gets melted. If you lost five pounds of wax because of any blunder or remissness on the part of our tinnerns, I will pay for it; and I beg to assure you, dear friend S., that we try to use all of our customers right. We do care very much whether the goods come early or late, and we will do almost any thing in the world we can do to expedite business, consistent with strict honesty and integrity. I am sorry if you have lost confidence in us; and I hope, after the above explanation, you will reconsider your decision.

A LETTER FROM SOUTH AUSTRALIA.

THE HONEY SEASON THERE FROM FOUR TO FIVE MONTHS LONG; 500 LBS. PER COLONY.

AMONGST other things to which particular attention has been called of late, the bar-frame hive has had a place. South Australia produces a heavy crop of honey, and under the old box system has been noted for years past for the quantity and quality of honey produced; but now since the A B C of Bee Culture has become a household book, the quantity of honey produced threatens to swamp the market. But this, I think, will work its own cure by exterminating those producers who will not take the trouble to put their goods in the market in good shape. We have a very heavy honey-flow this year; and as the season lasts for about four or five months you may imagine what a harvest might be gathered with the best appliance and good bees. We have no winter here—only a month or two of rough and rainy weather, so that in settled and cultivated parts bees can gather all the year; consequently the brood-nest is always pretty full. In country parts, the honey-harvest is gathered from the various species of eucalyptus, some of which bloom yearly, but the bulk bi-yearly. The red gum is a wonderful producer, and, being a very large tree, a single tree will produce many cwt. of honey, so that a strong colony of bees will gather, when the extractor is kept going, 400 or 500 lbs. in a season.

THE INFERIORITY OF BLACKS TO ITALIANS.

As this refers to the black German bee, we may look for still better results as the Italian and Cyprian blood asserts itself. I am running about 80 colonies this season, a few imported queens, a large proportion of hybrids, and a few blacks; and I would just like to say that I find the blacks are nowhere beside the Ligurian or hybrid in the quantity of honey gathered, or in general progress. They are very easily discouraged, and, I think, lazy withal. I expect about two to three tons of sections this season, of a quality which leaves nothing to be desired. I am just beginning to take off a few, and expect to be at that pleasant occupation until the end of April.

HOT WEATHER.

The weather at present is very hot. Last week we had it up to 112° right in the shade. A good many poor bees suffered in consequence, where not properly ventilated or shaded, by the melting of the combs. I am sorry to say I was caught napping myself by having some good queens in nucleus boxes with small entrances, and I lost six in consequence—one imported queen and four purely fertilized of my own rearing. None of the full colonies suffered, as I wedged up the bodies of the hive to insure plenty of ventilation.

By the aid of a gas-engine, 3½ H. P., I have turned out for others about 3000 hives and appliances. In hive-making I adopted the same principle of fitting as the four-piece sections. I had a machine made to my own order which takes out a row of ¼ dovetails. It works speedily and well, and gives, when knocked together and nailed both ways, a strong hive-body, as well as insuring each part coming up square into place. The Simplicity has been pretty generally adopted in these colonies, and I think meets all requirements.

PRICE OF HONEY IN AUSTRALIA.

At the present time, honey is bringing here,

wholesale, 3 pence for extracted and 6 for 1-lb. sections, which will pay well if a little attention is given to the apiary.

FOUL BROOD AND THE PHENOL CURE.

Our great trouble is foul brood. We are well acquainted with all the different phases and descriptions given from time to time in the bee-journals. For my own part I ceased to dread it after I got hold of phenol cure—not by feeding, for that would be impossible, unless by shutting up the bees—but by spraying bees and brood with a weak solution—1 in 400. I find that two or three sprayings is quite sufficient to eradicate the disease. The disease is so widespread that one can never be quite safe for any length of time. Some careless or ignorant neighbor may at any time communicate the disease. With no winter to contend with, we should be overrun or overwarmed with bees if nature did not put some check upon increase.

HOW TO GET RID OF SMALL BLACK ANTS.

I have been terribly troubled with small black ants—so bad that I could not keep any thing like a nucleus; in fact, they would put four or five frames of bees out of doors. After taking all manner of trouble to try to keep them off the hives I have set to work to try to poison them. To be safe in dealing with such dangerous stuff, I made 50 small feeders with the section groover, on the same principle as the Simplicity feeder, and then cut a piece of board large enough to cover the feeder. This piece of board was screwed on top by a single screw in the middle, but with a $\frac{1}{2}$ -inch strip of wood between at each end, so as to leave room for the ants to run in. When charged with poisoned honey in the grooves, the top board was securely screwed on, and one slipped under each hive where the trouble was. Judging from the attention they were receiving an hour or so afterward there should be a good many ants less in a few days. I think this will meet the trouble, and it is inexpensive.

For getting rid of large ants which congregate in colonies, I have found nothing so speedy as breaking up the ground, and then sinking a few earthenware basins so that the rims are flush with the surface. A little fire-wood ashes sprinkled into the basin makes the sides so slippery that no ant that once enters ever returns. A day or two will generally suffice to trap the greater part of the ants. Anxiety of mind to climb up the side of the basin will generally bring about death; if not, a little boiling water will. I have found the plan answer where every thing else failed. It is, like the other, inexpensive (if you borrow the basins and don't break any).

I should like to add my testimonial to the many you constantly receive, to the pleasure which the perusal of GLEANINGS gives; and not only pleasure, but profit—not profit measured by dollars, but by a standard which teaches us to “lay up treasure in heaven.”

THE TOBACCO COLUMN.

I am greatly interested in the smoker column. Thankful I am, after years of slavery, to be delivered from the bondage of a pipe, and to be free from a habit which was offensive to others, and miserably mean and selfish at the same time. I am glad to see so many others laying aside this filthy habit. Three years since, I laid the pipe aside, and intend never to touch it again, although so strong are the old habits that the very writing about the subject brings back the old desire to some extent; but I don't fear the enemy.

THAT JUBILEE EXHIBITION.

As probably you are aware, we are holding a jubilee exhibition this year which promises to be a grand success. I hope you will be represented. Victoria follows suit next year with a colonial centennial. Victoria is a wonderfully progressive colony. Melbourne, the capital (with which we are this month connected by rail) promises to be a second New York. We sadly lack a customs federation. We have different tariffs, and shut out one another's products. For instance, we can here produce fruit to any extent; but Victoria says, “We won't have your fruit, but will grow our own, even if not of so good a quality,” and so taxes imported fruit 2 pence. The same way with honey. I am offered in Melbourne 9 pence for comb, but would have to pay 2 pence for all that crosses the border. We are slowly, I think, working toward a federation of the Australian colonies, but we are dreadfully jealous of each other. LEONARD T. CHAMBERS.

Adelaide, South Australia, Apr. 4, 1887.

I am very glad, friend C., to get so good a report from Australia. Four hundred to five hundred pounds per colony is indeed wonderful, if you have many colonies that do that. Are you sure a single tree of any kind will produce as much as even 100 lbs. of honey?—Your testimony in regard to the common bees compared with Italians seems to be about the general verdict.—We have often thought of a hive-body to put together like a four-piece section; but unless kept well painted it will allow the water to soak into the dovetails, and hence we decided we should not like it, and the matter was dropped. I am glad to hear you also give a good report of the phenol cure.

BUMBLE-BEES.

ALSO A GOOD RECOMMENDATION FOR THE NEW BARNES COMBINED SAW.

WHY don't Prof. Cook, G. M. Doolittle, and others, in writing about bumble-bees, tell that the drones, or stingless bees, have a white, or rather yellow spot, on the head, and can thus be easily distinguished from the others. These are the fellows that sit on a mullein-top, as Mr. Doolittle says, and seem ready to fight any thing that comes their way. I have surprised people more than once by catching one of these white heads, as we call them, and when a boy, which was only a short time ago, my brothers and I used to catch the white heads and try to get other boys to do the same, but not tell them how to distinguish the stingless bees, and in that way have the laugh on them. But I believe we never found many who were willing to try the experiment. If I remember correctly, I have found these same white heads hibernating in red-cedar posts when split open in the spring. However, it was so long ago that I am not quite sure. Whenever you see a bumble-bee with a square yellow spot between the eyes, and always ready for fight, you need not fear him.

We have now owned a Barnes new combined foot-power saw for over a year, and are so well pleased with it that we feel like telling the readers of GLEANINGS, who may not be familiar with the machine, what we think of it. Our shop is in an unfinished house, and therefore was too cold to work

in during winter; but since the weather has begun to moderate we have been at work a part of the time. We have sawed out about 40 Simplicity bodies and covers, 10 nucleus hives, 180 metal-cornered brood-frames, dovetailed; also ten 2½-story hives. We have now 40 more hives in construction, and enough lumber grooved for ripping into frame-stuff which will make four or five hundred frames.

We have not kept any account of the time we worked; but to tell what the machine will do, we gave it a trial a few days ago. My brother held the watch while I ran the saw, and I ripped ten feet and nine inches of ¾-inch pine in one minute. The manufacturers of the saws claim that it will rip eight feet of one-inch lumber per minute; but if I have calculated correctly, what I cut would be equal to 9 13-32 ft., being almost 1½ feet more than is claimed for it. We would not take twice what ours cost us if we could not get another one. During the time we have had the machine it has been necessary for us to order some parts from the manufacturers, and the orders, though very small, received the most prompt attention, and we think any one having occasion to deal with the above firm will find them very pleasant men.

POLLEN THE SIXTH DAY OF MARCH IN CENTRAL MISSOURI.

Our bees gathered pollen on and perhaps before March 6th, but the sixth was the first we noticed. Since that time there has been some fine weather and they worked quite lively; but for the last few days it has been rather cool and windy. We went into winter with 12 colonies; bought three during the winter, one of which we lost; also one of our own died, leaving us 13. This spring we bought 18, and in transferring four of them we found one of them queenless. This leaves us 30 colonies, 16 of which have to be transferred. S. E. MILLER.

Bluffton, Montgomery Co., Mo.

BUMBLE-BEES, AGAIN.

PROF. COOK'S HEARTY INDORSEMENT OF DOOLITTLE'S OBSERVATIONS.

MR. EDITOR:—You do not know with what astonishment and pleasure I read Mr. Doolittle's article on bumble-bees, page 302, GLEANINGS. I am free to say, that not one man in 10,000, with no favoring circumstance to guide his observations and study, would show such accurate knowledge and observation as he evinces. It is a significant fact that has often interested me, that men like Messrs. Doolittle and Heddon, men who are naturalists by nature, are almost sure to make a striking success of whatever they undertake, unless, forsooth, they are naturally so indolent, and wanting in energy and push, that there is no foothold in their lives for success. This is why I would incite in the mind of every child a love of nature and its study. It is an easy task to stimulate such a love; and it serves wonderfully to aid in the struggle for success in this practical age; and, best, by leading the mind and thought toward good things it helps to fortify one against the evil that is in the world. What a rich mine of pleasure our good friend Doolittle has found in his close study of every thing about him! What a wonderful aid this cultivated observation has been to him in his bee-keeping life! and through him it has blessed every bee-keeper in the

land. What helps any honest laborer in any useful occupation, blesses the world and rejoices the All Father.

Yes, I feel sure that the queen bumble-bee hibernates. Deep in the ground or in some other protected spot she survives the winter, and awakens with the lilacs and apple-blossoms, to her important work.

Again, my observation agrees with that of our friend, in the statement that the egg is placed in the pollen mass. The cell is formed by the food-taking of the hungry, rapidly growing larvæ. Afterward this cell is waxed and is made a honey-cell. This is what friend Doolittle and I used to pilfer from the poor bumble-bees. Often we learned that the curved cimeter of the bumble-bees is well prepared to protect their precious stores, and I am not the one to say that it did not serve us right.

I am not prepared to say positively that there are not large and small workers, but I am doubtful. Several times I have chloroformed whole nests, and examined every bee, only to find workers, queens, and drones. The young unimpregnated queens were smaller than the old queen, and larger than the workers. We will examine further, friend Doolittle. You know that prince of observers and naturalists, Huber, said there were two kinds of worker honey-bees. We do not think so now. Careful observation and examination make me quite sure, in some cases at least, the bees in the bumble-bees' nest correspond exactly in sex and kind with our honey-bees. I wish our friend would send me his six species next year. I will report the names in GLEANINGS.

Our students have often asked me about the shade-bees. Every bee-keeper would understand at once why such bees would never sting. Our friends clubbing the shade-bees with dirt-clods, as many a boy has thrown a stone to see his sportive dog run for it, is as interesting as it is exceptional. What other reader of GLEANINGS ever did that? And who have noticed the swarming-out over nests in August? How I wish every boy in the country could have the privilege of a walk once a week with our friend Doolittle, through meadow and woodland! What a new world this would be to them! Add to this the weekly visits of the *Youth's Companion*, and how few of our boys would go to the bad.

As to close in-breeding. I do not believe nature invariably abhors close in-breeding. She abhors imperfections; and if such are closely inbred she exterminates the whole race. Many plants have to breed close, and thrive at the same time. Bates and Collins originated our grandest strains of short-horns by just this close in-breeding. It is the most potent instrument in the hands of our best breeders to-day. With the bumble-bees, what a gain, in the way of security from danger, is this habit!—such a gain that it overrides any disadvantages by way of close in-breeding in importance. The man who took the leading premium at our last State Fair had bred his short-horns right in for three generations. I know of another excellent breeder who did the same with marked success for a much longer period. I should much prefer to breed in closely with good animals, than to use a poor out-cross. A. J. COOK.

Agricultural College, Mich., Apr. 26, 1887.

I am very glad indeed, friend C., to hear you speak such kind words of our old friend.

One of the things that first struck me in his early writings was his habit of close, keen observation, and the enjoyment he seems to take in digging out Nature's secrets. Will the friends now pardon me for saying that we have now devoted as much space to bumble-bees as we can spare? The honey season is upon us, and more important matters are pressing.

MORE ABOUT OUR CELLARS.

TERRY ON THEIR CONSTRUCTION, VENTILATION, AND TEMPERATURE.

FRIEND ROOT:—A correspondent thinks I was somewhat mistaken on one point, in a late letter about our cellars. I said, in substance, that when the burning fire took air from the rooms, more would have to come in from some quarter, and that, under ordinary conditions, much would come from the cellar, right through the loose inch floor-boards. Also that the tighter the doors and windows were made with weather-strips, etc., the more air would be drawn from the cellar. Now, our friend thinks that, if the doors and windows of the cellar were shut up tight, as they are during the cold weather, little or no air could be drawn into the living-rooms, as there would be little chance for more to be drawn into the cellar to fill its place. This depends largely on circumstances. If the cellar wall was built of hollow bricks, and these bricks were made of sewer-pipe clay, and glazed, and the doors and windows shut very tightly, it would not be an easy matter to draw much air into the cellar; still, there would always be some—enough so that it would be wise to plaster the cellar overhead and keep it as pure as possible.

The writer's cellar wall is made of these hollow bricks. But how many cellar walls do we find built in this way? A very great many are built of common sandstone, through which the air will go almost as readily as through an inch board. Air doesn't come through the mortar on the sides of the living-rooms readily; and if the doors and windows are made very close-fitting, you may be sure that, with the ordinary loose inch floor and sandstone cellar-walls, a large part of your winter supply of air comes to you by way of the cellar. This is bad enough; but what shall we say when a bank of manure is put up around the cellar-wall to keep the cellar from freezing? I wonder how many who use manure for banking ever thought that their breathing-air in the house would be tainted all winter with that manure. Perhaps not one; but still this would be found to be the case as a rule. So we want to be careful and have the outside of our cellar wall clean as well as the inside.

The writer rode by a house thus banked up, last winter. A hearse and a number of teams in the yard looked as though there had been a death there lately. I could not help but wonder if the condition of the air they had been breathing had not hurried some loved one away sooner than was necessary. As one goes to the North he sees manure used to bank up cellars much more than in this latitude. It is handy, as every one, almost, has plenty of it; but certainly no thoughtful husband would use it outside of a sandstone wall, where the dear ones lived in rooms over the cellar. Sawdust or even dirt would be far better. But in our latitude there

is no possible need of any banking. It looks badly at the best. A banked-up cellar is very apt to be kept too warm for the good of the vegetables. Hang two thermometers up in the cellar at the coldest points. Early in the winter leave the windows open on the south and east sides, until you get the temperature down to 35° at least. When there comes a cold night, and the thermometers show a temperature close to freezing, light an oil-stove for an hour or two, warming it just barely enough to tide you over the cold snap.

We never bank up our door or windows in the least, and some 18 inches of wall are exposed all around the house; but we never have anything freeze. I doubt whether we burned more than 10 cents' worth of oil during last winter. Perhaps half a dozen times the stove had to be lighted for a short time. We have plenty of choice eating-apples yet. Very few rotted. I know many farmers who kept their cellars banked up too warm, so as to have them able to stand a cold snap. Their apples were all rotten long ago. Some of them have sprouted their potatoes already. A thermometer and oil-stove, and a little thoughtful labor, would change all this. And then the good wife would find the oil-stove so nice to heat the irons or boil the tea-kettle some hot day in the summer. Even if one does bank up the cellar, the thermometer would show him, oftentimes, that he was keeping it much warmer than was necessary. A thermometer costs but a few cents; but I venture to say, not one farmer in ten ever keeps one in his cellar.

A cellar kept down near freezing, all winter, would make the living-rooms above colder, with only a thin board floor between; but plaster it overhead and put building-paper under carpets (the best way to keep impure air from coming up), and you will not be troubled with cold floors.

A vegetable-cellar somewhere else than under the dwelling-house would be better, perhaps; but I have been trying to show in my two letters how we could take cellars as we find them, and used as they are used, and so manage them as to run almost no risk to our health and still keep our vegetables in the best possible condition.

I am afraid you will say that I stopped too quick again, so I will add that to-day, May 2, we have bushels of Peck's Pleasant apples, not a late-keeping variety by any means, that are sound and nice to eat, in our cellar. And we have 50 bushels of potatoes for seed that have not sprouted to speak of, and we hope to be able to keep them back another week or ten days. Our earliest potatoes have sprouted a little. As a rule we can keep them back until this date.

Friend Root, when I wrote that letter that made you "almost provoked because I stopped so suddenly," I looked up at the close and saw how many pages I had written, and thought of what you said in GLEANINGS, not long ago, that friends must make their letters short, or you would have to cut them down, etc., and I just wound right up as quickly as possible. I believe you were right too. We are not heard for our much speaking. This reminds me of a story my father used to tell:

When he was in the theological seminary the president once told the young ministers that if they should take a hatchel (the younger readers of GLEANINGS will have to ask their grandparents what this is), and stuff it full of tow, cramming in all they possibly could everywhere, they could

then sit on it and ride to Boston; it would make a comfortable seat. "But," he says, "young men, if you should pull the tow all out you would find it a very pointed seat. Now leave the tow out of your sermons. Let them just be full of clean sharp points, that can not fail to prick the hearers."

We do not want too much tow in our articles either, so that, when one gets through reading, the points will have been all smothered in his mind by the mass of unnecessary words. T. B. TERRY.

Hudson, Ohio, May 2, 1887.

Friend Terry, you have given us some very important suggestions, and I have been for a long time thinking of the importance of keeping our cellars, especially our vegetable-cellars, as cold as possible and still avoid freezing. A good deal of attention has been given to cold-storage rooms, that cost ever so much money; but I believe it has been decided that fruit and vegetables of many kinds can be kept almost as well on the plan you give—that is, keeping the air in the cellar cold by opening and closing the windows at the proper time. I can readily understand how the coal-oil stove would be very much better, and I think cheaper too, than making our cellars too warm just because of the rarely occurring severe days and nights that might let the frost in. This subject is intensely interesting to me; but perhaps I shall have to set an example too, by being brief. But I want to say, before closing, that I do not believe that a single one of the 7000 subscribers to GLEANINGS has thought that *you*, friend Terry, had even once written at too great length. Your talk concerns the homes we live in, and this all-important matter of the health of the inmates; and the most of what you give us has never appeared elsewhere.

ABOUT SPREADING BROOD.

FRIEND DOOLITTLE TELLS US HOW TO DO IT AND HOW NOT TO DO IT.

FEARING that all do not understand just how to manage the spreading of brood so as to have it an advantage rather than a disadvantage, I thought a few words at this time from one who has practiced it for the past 15 years might not be amiss. Some think that at best there is no gain in such an operation, or, at least, not a gain proportionate to the labor involved; but from several tests made by leaving whole rows of hives through the bee-yard undisturbed, while a row alongside had the brood spread as about to be given, I find those manipulated gave results above the others more than double enough to pay for the extra labor. The trouble with most of those who try the plan for the first time is, that they begin to manipulate the brood too early. There can be nothing gained where there are three or four combs one-fourth full of brood, by spreading them apart and putting an empty comb between; for by so doing we simply spread the brood out in an unnatural position, and work on the plan of scattering the heat instead of concentrating it. Besides, as long as this state of affairs exists they have already got brood in more combs than they should have; for all will see that, if all this brood were put in one comb, and that comb placed in the center of a chaff hive made for only one

comb, the bees that hardly covered it before could hardly crowd into the space it now occupies.

To get at what I wish to illustrate, let us suppose that we could get that ordinary colony of bees with its brood in four combs as above, all on one comb, and no room for the bees except in this space, it will be seen that quite a proportion of the bees would be obliged to cluster outside. To obviate this outside clustering we will enlarge our hives so as to take one more comb, which comb is put in. Now having our heat and bees condensed to the right proportion, we would find that the queen would lay in this comb at the same rate she would in July, filling it with eggs in three or four days; while, had we not done this, the brood in the four combs with a whole hive to carry off the radiating heat would not have advanced to the amount of one-sixth of a frame. In a few days, more young bees from our first frame have hatched to such an extent that they are again crowding out at the entrance, when we once more enlarge the hive and put in another comb (putting it in the center this time), which is filled as quickly as before, and so we keep on, till one hive is enlarged to the breeding capacity of the queen. Does any one doubt but that we shall have a hive full of brood and bees long before we should if nothing had been done? If such doubt exists, an experiment or two along that line will convince any.

Well, now, to practical work. As soon in spring as the first pollen appears, shut the colony on to the number of combs containing brood, using something to confine the heat as much as possible for a division-board. If these combs of brood do not contain honey enough, use a feeder such as I described a few months back for that division-board, and feed, or leave combs of honey beyond the board so the bees can have access to it. Now leave them till the two central combs have brood clear down to the bottom outside corners of the frames; for manipulation previous to this would not help a bit, as they already have all the chance for spreading their own brood that is needed. As soon as you find the two central combs thus filled, reverse the brood-nest, by which I mean put these two central combs of brood on the outside, and those outside in the center, when, in a very few days, we shall have our combs and colony in just the shape of the supposed colony we spoke of above, and are to proceed in the future on the same plan. The main idea is, in the concentrating of the heat, and that in such a way that the young brood and eggs are always in the warmest part, rather than all around on the outside, or in the coolest part, as they are in the manipulated hive. It will also be seen, that, if we work as above, there is not the least shadow of a chance of chilling the brood; for room is given only as the bees need it. The spreading of the brood in a full hive where there is brood in from four to six frames, and those only from $\frac{1}{4}$ to $\frac{3}{4}$ full, is only labor thrown away, and a risky operation besides; for the bees have already too much room; but the concentration of heat, and the management as given in this article, is a sure road to success; or, at least, so says an experience of a dozen or more years.

Borodino, N. Y., Apr., 1887. G. M. DOOLITTLE.

I quite agree with you, friend D., only I do not believe I would want to undertake crowding the bees on to one frame very early in the season. I have done it in the

hot summer months with good success, but it always seemed as if they needed about two combs to make a start, and even three seems a good deal better. Perhaps the L. frame may work a little differently from the one you use; but I believe if I were commencing the first of April to contract, I would not reduce any of them to less than three combs. If they could not fill the space I would let them manage their own way until they could; and when the little colony gets so strong as to crowd outdoors during very warm weather in the month of April, I would be a little slow about giving them another comb. A severe frost may not only crowd them all into the hive, but perhaps so near the center of their two or three combs it might leave some brood exposed. With *good packing* about three combs, there ought not to be much danger.

There is another point I feel a little undecided about: When bees have a little unsealed larvæ on one side of the comb, and cells filled with pollen right opposite on the next comb, is it ever advisable to move these combs so as to upset the arrangement? I have watched it quite a little, and it always seemed to me as if it were asking your wife to get breakfast as quick as she does ordinarily, with the cook-stove put in the cellar and the dining-table upstairs. She usually wants the cook-stove not only on the same floor, but pretty near by the breakfast-table; and the bees plainly tell us they want newly gathered pollen about as near the unsealed larvæ as they can possibly place it. Now, if you will take an outside comb and put it in the center, a good deal of hard labor for the little chaps is caused by the transposing and upsetting. The children will wait to be fed, while the breakfast-table is away around on the other side of the comb—may be a whole comb intervening between the food and little ones. I know they will change things about and get things handy in a pretty short space of time; but I have thought that colonies that were not mixed up in this way made the best bees.

T. P. ANDREWS' HIVE-CART.

HOW TO MAKE IT.

THE cart I use in my apiary (see cut, Jan. 1st GLEANINGS) was made according to directions given me by a bee-keeping friend by the name of S. Smith, of Mattoon, Ill. The wheels are 28 inches high, and are made of $\frac{3}{8}$ -inch surfaced pine lumber which should be as much as 16 or 18 inches wide. Each wheel consists of three disks of lumber; the central and largest one is 28 inches in diameter, made of two widths of lumber. The others are 12 and 20 inches respectively. These two smaller disks are beveled around their circumference to a feather edge, and securely nailed, one on each side of the large disk. The grain of the smaller disks crosses that of the large one, thus giving it strength and thickness enough at the center to hold the boxing in very firmly. This consists of a piece of $\frac{3}{8}$ -inch gas-pipe, $3\frac{1}{4}$ inches long. The axle proper is made of a piece of iron rod, a trifle smaller than the bore of the gas-pipe, into which the axle is slipped, and around which the box revolves. Flanges are welded on the axles

at the inner ends of the boxes. Holes are punched at the outer ends of the axles, and linchpins hold the wheels on.

The body of my cart is also made of pine lumber. It is about 4 feet long and about 20 inches wide. It is made to hold three hives or comb-boxes at a load. The depth of the body is six inches. The cut is not entirely correct. The cart is not wide enough to take in two hives side by side, but is *long* enough to take in three hives. The side-boards do not taper out into handles like a wheelbarrow, but are cut off on a bevel, and are connected by a cross-piece that can be grasped by one or both hands. The axle is made as short as will permit the wheels to turn freely without rubbing against the side-boards. A three-inch cross-piece connects the two side-boards. To this the iron axle is fastened by two carriage-bolts, the heads of which have been cut off and the ends bent into hooks which grasp around the axle. The cart should be supported in a horizontal position by two legs like those of a wheelbarrow placed near the front end. The lumber and iron work of the cart cost about one dollar, and is, in my opinion much, more convenient in the apiary than a wheelbarrow. It is narrow enough to pass through an ordinary door, so that it can be drawn with its load of combs into the honey-house.

Farina, Ill.

T. P. ANDREWS.

Thank you, friend A. And so it transpires that the home-made cart was an "iron ex," after all. Your plan of construction is quite ingenious; and if you draw the cart in when it rains, those pine wheels will last a good many years, and do much service.

A WELL-SPENT DOLLAR.

A TRUE STORY, WITH A MORAL TO IT FOR THE BOYS.

MANY years ago there lived in this county a farmer by the name of Mr. W., who had, among other children, a son about fifteen years of age, by the name of Thomas. He also owned a negro boy of about the same age as Thomas; and as these boys were thus thrown together they naturally became very intimate. Among other diversions they learned to play at cards some time before Mr. W.'s death, which event left them as the only prospective support for the family.

When the season for farming was at hand, the neighbors began to watch to see how the boys would work. It was soon apparent that something was wrong, and one old neighbor by the name of Mr. R. made special search to find the trouble. He was not long in tracing it to the cards; and, after much contemplation, he decided upon the remedy, which he carried out as follows:

Upon meeting Thomas one day he said to him, "Thomas, I wish to buy a pack of cards—the kind you play with."

"I declare, Mr. R., I do not know where you could get them," was the reply of the boy.

"I want them very much; I will give a silver dollar for them," continued the old man.

Now, as this was about twice the value of a new pack, and as the cards owned by Thomas were somewhat worn, this was too much for him; and, after some hesitation, he replied, "Mr. R., I have a pack, somewhat soiled and worn, that I will sell you for that amount."

"Very well. I care nothing for their condition," said the old man, as he paid the boy and received the cards.

The boy was at first delighted with the trade; but upon seeing Mr. R. take out his pocket-knife and begin to cut the cards into small bits, he, in surprise, exclaimed, "Mr. R., what on earth do you mean? Did you not just pay me a dollar for those cards?"

"Yes, my boy, but these are the very cards I wanted; and the only purpose I had in buying them was to get them out of your possession. I have seen for some time what a disadvantage they were to you, and what a trouble to your mother. You know, Thomas, how poor I am, and how hard it is for me to earn money. Now, if I can make this sacrifice for you, can you not resolve to buy no more, and never to play them again?" By this time the boy was in tears; and while I do not know that he made a promise, he acted ever after as though he did; and when he had grown older he joined the church and has since lived an active and consistent member, always taking a lively interest in the welfare of the young, to whom he often relates the incident given above. W. H. GREER.

Paris, Tenn., Apr. 11, 1887.

Well done, friend G. I don't remember ever having mentioned the matter in print, but I always feel greatly worried and troubled whenever I discover that any boy, or girl either, is learning to play cards or is attending card-parties. When I started planting my basswood orchard a young couple rented a farm just across the road. They were a nice, bright young couple; but it saddened me to see that they thought it was the thing to have their young friends visit them and have card-parties; and card-playing got to be so much the order of the day that on one occasion these young friends wasted one bright summer forenoon in their card-playing. Our young farmer never hitched up his team, although the weather was beautiful, and the season at just such a point when every farmer, young and old, ought to be just jumping to get the work along, and his wife left her breakfast-table without even washing the dishes until it was dinner time. The next year they rented another farm, and they may be both in the county infirmary by this time, for aught I know; for it is a fact, that one little foolish bad habit like this may wreck a life. No wonder the boys did not prosper with their farmwork.

HEADS OF GRAIN FROM DIFFERENT FIELDS.

WIDE FRAMES VS. CASES; CLEANER SECTIONS FROM THE FORMER.

WHILE surplus cases are under discussion I should like to put in a word for wide-frame single story cases. It is impossible in this locality to produce gilt-edge honey unless the sections are protected on all four sides.

When my honey is ready for market, the sections look almost as clean as when first put on the hives. This will not be true where cases are used without wide frames, except in rare instances. I know by experience that this is so; for wherever I have tried

to buy comb honey to sell again, unclean sections have been the one great drawback for me to do a successful business at it. A great many bee-keepers do not think this matter of having clean sections around their honey makes much difference; but I know this one thing has done a great deal toward lowering the prices of comb honey. Even storekeepers have fallen into this same rut. Go into almost any store in any town or village where honey is sold, and you will find it, nine times out of ten, just as it was taken from the hives. Wake up, brother bee-keepers! put your comb honey on the market looking neat and clean, in small clean packages, and you will find less trouble in selling at much better prices. I should like to ask if any one has ever tried the perforated zinc for separators.

W. H. SHIRLEY.

Mill Grove, Allegan Co., Mich., Mar. 22, 1887.

Very true, friend S.; but Dr. C. C. Miller claims that he can get just as clean or cleaner sections from the T super when the slatted honey-board is used, than from wide frames. If we are correct, he told us that the sections, when taken from the T super, take less cleaning than the sections when taken from the wide frames.

BEES AND RAILROADS.

I have lately noticed in GLEANINGS several inquiries about keeping bees near a railway, mill, or factory, the idea prevailing that the noise and jar are prejudicial, especially in winter. I give my experience. I have kept bees for the past four years near a railway, not four rods distant, with a roller-process gristmill within four or five rods, and I can see no difference between my bees and my neighbors' as to wintering, etc. I believe the bees get used to the noise as we do. Every train through the night used to wake me, no matter how soundly I slept; but now I never hear them. The soil is a firm clay, and the road-bed is level and solid, with good rails; but there is a large traffic, and heavy trains. My bees, 60 colonies, are wintered on summer stands clamped in sawdust, but so the entrances are open. They are in fine condition. E. J. BURGESS.

Tilbury Center, Ont., Can., Apr. 22, 1887.

HOW TO GET RID OF A HYBRID COLONY.

Last summer, having a black hybrid colony of bees that I desired to get rid of, I took brood from them three or four times, each time leaving a comb of eggs. I used the brood to build up a nucleus of pure bees. When I found a choice pure colony superseding their queen I inserted one of their queen-cells in this black colony, after taking out their queen. As I was busy I did not again go to that colony for several days. When I did go I found a beautiful Italian queen. As I had no other place to use her I built up the colony with brood from other colonies that could spare it, the colony being now the size of a strong nucleus. When fixing up for winter I found them a fair colony; but as soon as set in winter quarters they began to die off. At the end of a month, as there were so many dead bees thrown out of the entrance, I marked them dead. I could not imagine what could be the matter with them, as most of the other colonies were so quiet, and were throwing out so few dead bees. As their hive was at the bottom of a pile of colonies, and in the center of the cellar, I could not very well examine them. After six weeks or so they seemed quiet — in death, as I supposed. But when set out

this spring I found a beautiful small Italian colony, large enough to build up by the time white clover blooms. Now, I wish to ask why those black bees died off so fast the fore part of winter. Was it not because their vitality was injured by caring for so much brood? They had a very vigorous queen, and I must have taken away eight or ten combs of capped brood. Mr. Axtell said it was a pity to kill any queen so productive, even if she was a black hybrid.

MRS. L. C. AXTELL.

Roseville, Ill., April, 1887.

I think you are doubtless correct in the matter. The black bees died off because they had been so severely taxed, and were perhaps prematurely old. The younger Italians doubtless took their place, and saved the colony from ruin.

ANOTHER WAY TO MAKE T TINS.

I have accidentally learned how to make the T tins, using the common folder found in every tinshop. Although of no benefit to you with your machinery for making it of one piece of tin, it may prove of benefit to hundreds of others who may want a few tins quicker than they can get them of you. I was having some L tins made of light tin, for use not connected with bee culture, and our tinner suggested that if I wanted them stiffer he could fold one edge on $\frac{1}{8}$ inch before they were folded into the L shape, which left them like  FIG. 1, and very much stronger; and by slipping two together I found I had quite a strong T, and no solder required to hold them—simply prick punch them in a few places, and they seem as firm as if made of one piece, and I think they are as strong (or a little stronger) than if made of one piece, as there are three thicknesses of tin at the top edge. To make them I would cut one-half of the tins 3-16 wider than the others, and fold one edge 3-16, and then  they are both of a width, as in Fig. 2; then fold each one into the L, and slip the tins together, and then you have a T, as in Fig. 3, and you will be surprised at its firmness. I trust that you will get the idea, and take it for what it is worth.

O. R. COE.

Windham, N. Y., March 25, 1887.

Thanks, friend C.; but we had already made them on this plan some time ago. It makes very nice stiff strong ones; but it is more work than to make them as we now do with special machinery. The idea may be of value to many of our readers.

HOW TO MAKE ROBBERS BECOME DISGUSTED WITH PILFERING.

I undertook to look through a hive a day or two ago, but got a job on hand by it, and had to close them up again quick, as another colony commenced robbing them with a will. I have noticed that some object to Italians on that account. I have but one colony of Italians, and can control them as far as their disposition to rob is concerned, much easier than some blacks I have. My Italians start often, but I can stop them with but little trouble so far. One colony of blacks, however, in particular, I have most trouble with. My plan for stopping may not be new; but as I am a new hand with bees it is new with me. I made a light frame, and covered it with wire cloth. It just fits in the portico of the hive, and extends out some six inches. When I

find the bees are robbing a hive I put it on until I have a considerable number of the robbers caught as they come out loaded. I then take it off, and, holding the open end down, step away a few feet from the hive, turn it up, and let the caged robbers fly out. I can then easily see where the most of them go. I next put my wire cage on the hive where the most of the robbers are, and leave it there some time, keeping any more from coming out. After those coming in worry around awhile, I slip it out, when the incoming bees pile in in a hurry. I put it on again, keeping the inmates in the hive some time. They get bothered so that they conclude to stay at home. I usually conquer them in a short time by this means. The Italians so far have been easily conquered in this way, but it takes longer to satisfy that one hive of blacks.

R. J. MATHEWS.

Riverton, Bolivar Co., Miss., Feb. 15, 1887.

The plan you suggest, friend M., is ingenious, and, so far as I know, it seems to be new. Most of the robbing is usually done by a few certain hives, and sometimes it is one hive that is keeping the whole apiary in an uproar. Another plan to determine which hive it is that is guilty is to sprinkle flour on the backs of the bees as they come out of the hive that is being robbed. While doing this, have an attendant watch the entrances of your different hives. Shutting up the robbers has been tried to some extent; and with a hive that has a portico on it, it may do very well; but in hot weather there is always danger of smothering, unless a large opening like a portico can be covered with wire cloth.

HONEY STOLEN.

On the night of the 17th of this month the building in which I had my honey stored was entered by thieves, and about 300 lbs. of honey stolen. There were 16 crates already put up and stamped with my name in two places; also another stamp in which to insert gross tare and net weight of honey, ready for market; the rest was in cases (Heddon), just as I had taken them off the hives, and some loose sections. They also jammed some sections in a box, etc., which they left in a greatly damaged condition. My loss is about \$35.00. The greater part consisted of white clover and basswood. I have always been free to give to my neighbors and friends ever since I have kept bees. I have given away several dollars' worth, and have the good will and respect of all of them so far as I know, having lived here 43 years. I think the parties who took it would steal my pocket-book, horses, or any other property. I write this, trusting that it may serve as a warning to the fraternity to keep a lookout. Any suggestions from you as to what steps I should take to trace it, or to prevent a like occurrence, will be thankfully received, as I have about 1500 lbs. left which they may try again, if they are successful this time.

WM. H. GRAVES.

Duncan, Ill., Nov. 25, 1886.

As a rule, friend G., I believe a crop of honey should be kept under lock and key—not only to keep the honey from being stolen, but to remove temptation, and to keep people honest. I think I should try pretty hard to find where such a quantity of honey went, if possible. The good of your community demands that the culprit be

brought to justice. As such a quantity must be disposed of sooner or later, it seems as if it would not be a very difficult matter to get hold of some clew to it.

DO KING-BIRDS SWALLOW THEIR VICTIMS? A FEW FACTS WHICH SEEM TO PROVE THAT THEY DO NOT.

In GLEANINGS I find, on page 295, a letter from L. Williams, in regard to the king-bird. My experience is quite different from his. My observations are, that it catches the bee and holds it in its beak and sucks the nectar from the bee, then drops it, and is ready for more. I have kept bees for several years, and there are times during the season when the bird is very troublesome. I have killed hundreds of them, and watched them closely, and I have taken the pains to open a large number of the birds, but I have never found a bee inside of the bird, and I have shot them and opened them instantly after seeing one with the bee in his beak. The king-bird is the only bird that I take pains to get out of my apiary, and I have sworn vengeance on him.

Bees in this part of the State this spring are not in first-class condition. Some have lost heavily. My loss is about 10 per cent, and I consider this a good showing. I have on hand at this writing, 115 stands. Some are light, but the majority are in very good condition, but are getting short of stores. We are having a cold, dry, backward spring.

W. A. WICKHAM.

Clermont, Iowa, April 21, 1887.

A KING-BIRD STUNG TO DEATH.

In GLEANINGS for April 15, page 295, L. Williams writes, among other things, "King-birds, and why queens disappear." Now, one of our children found a dead king-bird near our apiary, with about a dozen bee-stings in his breast and under his wings. Wife cut it open and examined its crop, but she found not the sign of a bee inside; but a few seeds and stones instead was all it contained.

J. R. WILSON.

Carlisle Springs, Pa., Apr. 19, 1887.

The two reports above seem to indicate that the birds do not swallow the bees so that they are found in their crops. The report in the A B C book, however, makes them out exceedingly guilty. It is possible, however, that they simply kill the bees and squeeze out the honey, throwing away the mashed-up bodies, so that none of these things would ever be found in their crops. I think the evidence is pretty conclusive that they do kill bees.

A FEW INTERESTING FACTS CONCERNING THAT CALIFORNIA SWARM FOUND IN THE OPEN AIR.

I observed in GLEANINGS, page 608, 1886, a cut of a swarm of bees in the branches of a tree, and a description of it as belonging to Southern California, and taken from a photograph sent you by a friend. I can give you the history of that swarm. In the summer of 1883 a swarm of hybrid bees clustered on the branches of a mulberry-tree standing on the grounds of O. W. Childs, in this city. The bees built three sheets of comb, nearly a foot long, the first season, and came through the rainy season in good order, though not protected in any way, except by the foliage of the tree in the summer. The next season they built the combs two feet long and added an additional comb on each side of the origi-

nal outer ones, filling the outer combs full of honey, as could be readily seen, as they were not more than twelve feet from the ground. Hundreds of people visited the place at different seasons of the year, to see the bees at work, and wonder how they could prosper so without any care or protection whatever. The tree stood near Mr. Childs' carriage-house, and during the colder days of the third year of their squatter sovereignty they began to trouble the horses occasionally, and I was requested by Mr. Childs to take the bees away, if I desired to do so. I accepted the offer; but before taking them down I had the photograph taken from which your cut was made. I was about making arrangements to have a cut of it made, with the intention of making a little money out of it; but your publication of it nipped it in the bud. I can't imagine how your friend could have secured a photograph of it, as I arranged with the photographer to have the exclusive control of all his work on that subject, and spent some ten dollars in money, besides time, in securing the picture, and all I made of it was the bees that Mr. Childs gave me. I took the bees out to my apiary in the San Fernando Mountains, and am working the stock for increase, and I believe I have some bees that will compare favorably with the best imported bees that I have seen. In the honey season they come quick and go quick, carry good loads, and are as prolific as the Holy Lands.

Los Angeles, Cal., Feb. 17, 1887. C. N. WILSON.

I am sorry, friend W., if there was any underhanded work about obtaining the photograph. Is it not possible this was taken from a photograph of another one strikingly like the one you have mentioned? It would be nothing strange if two colonies, similarly located, should resemble each other. We instructed the engravers to spare no expense in making a nice engraving, and they followed directions so completely that the cut cost us, we believe, some thirty or forty dollars. There might arise a question here as to the moral right of the picture. We were an innocent party in the transaction; but so is a man who buys stolen goods of any man; yet the law permits the rightful owner to take it when he can find it. Of course, you are welcome to your photograph back again, if you want it; but the next question is, Who is the lawful owner of the engraving that cost us so much money? We are quite ready to do what seems right in the matter.

HOUSE APIARIES.

Some will prefer and use house apiaries, and of course all will want the best. I have used mine another year (as described in GLEANINGS, page 744, 1885, and page 105, 1886.) I like it much, as it is so handy. I do all my extracting, transferring, and dividing, in it without any trouble from bees. I find they sting less. My house does not heat up as Mr. Clark says.

\$365 FOR SEED FROM 12 ACRES OF ALSIKE SOWN.

Farmers sow lots of alsike clover here. There is more than 100 acres sown within two miles of my apiary; one man took a load of alsike seed to Adrian, a short time ago, that brought him \$365, which grew on 12 acres, and that was not all of the crop. You are right as to the quality of the honey from it. I like it the best of any, and most of my customers the same. I obtained only about 600 lbs. of honey, principally comb honey. I had 11

swarms in the spring, mostly light. I had them all to transfer. I made them into 24, and doubled back to 14. I have bought 24. I have now 43. The 14 are in hives the same size as the new Heddon hive, but not closed end frames. The frames can be taken out when either side up. I like them much. I will explain them more fully some time.

Holloway, Mich.

H. L. HOXIE.

A SUGGESTION IN REGARD TO THE LOOSE T TINS.

Do not think I have not been an interested reader of the T-tin discussion, for I have used 60 of the T-tin supers inside of my S. hives. They work well in chaff hives too. I have become a convert to Dr. C. C. Miller's theory in regard to loose T tins. How well I shall like it in practice remains to be seen. There is one point about it which I have not seen in print. It allows an outward spread to the sides, which nailed tins do not allow. This would cause it to slip off easier. Tell the doctor to use a straight-edge, two, three, or four inches wide, under his mallet, and long enough to reach across his super when driving it down, instead of driving directly on the super, and I think he will be better pleased.

J. REYNOLDS.

Clinton, Kennebec Co., Me., Apr. 25, 1887.

SQUARE CANS VERSUS KEGS FOR SHIPPING.

When we ship in kegs, our kegs are thrown in free. Is that the case with the square cans, or do you get any pay for them? or are any returned, and at what expense by the express companies? We get the five-gallon kegs delivered here at 27 cts. each; 100 of your square-can cases, delivered here, would cost over 80 cts. each, or over 40 cts. for what we pay 27 cts. for in a keg. This difference would be quite an item out of the profits. I think the cans are very much the best, especially where we need to warm up candied or cold honey; but the extra expense is in the way. We use from 100 to 150 kegs here per year, and we could get up an order for 100 cases for this season's use if you can tell us of some plan to get back part of the expense.

Oneida, Ill., Apr. 11, 1887.

W. M. KELLOGG.

We always charge for the square cans and boxes to hold them, friend K. I never heard of any one returning them. They are generally utilized for some other purpose, when the honey is taken out, I believe. I have never heard of kegs so cheap as you mention; but our experience has been that they are always more or less leaky. I do not know but that our foul brood came from purchasing honey in kegs, and then the kegs got to leaking, and the bees got to working on them.

HONEY-DEW AND PLANT-LOUSE NECTAR: THE SUBSTANCE AS FOUND IN THE EAST.

Not long since I came across this bit of history, which was of great interest to me, and may be, perhaps, to some of the readers of GLEANINGS:

"Forsk. says, the caravans of Mecca bring honey from Arabia to Cairo, and that he has often seen honey flowing in the woods in Arabia. It would seem that this flowing honey was bee honey, and this fact illustrates the story of Jonathan. But there is also a vegetable honey that is very plentiful in the East. Burckhardt, speaking of the productions of the Ghor, or valley of the Jordan, says one of the most interesting productions of this place is the Beyrouk honey, as the Arabs call it. It was described to him as a juice dropping from the

leaves and twigs of a tree called 'gharrab,' of the size of an olive-tree, with leaves like those of the poplar, but somewhat broader. The honey collects on the leaves like dew, and is gathered from them, or from the ground under the tree."

It would seem that this vegetable honey is identical with our honey-dew, and the tree upon which it is found seems to be quite like our poplar (tulip), which is often infested with aphides. The secretion there is evidently more profuse than we know any thing of, if it "drops from the leaves" and may be "gathered from the ground." In speaking of this very thing, I notice Cheshire says, "I saw falling in the sunlight, a thick, constant shower of minute drops, which were being expelled from the anal apertures and nectaries of the aphides infesting the leaves." I notice Cook distinguishes between the aphide nectar and the "real honey-dew which the leaves distill." F. C. BLOUNT.

Lawndale, Ill., Feb. 25, 1887.

DANDELION.

Will you please favor me with answers to the following questions?

1. How many acres of dandelion does it take to keep one hundred colonies busy?

2. How late in May do bees usually work on dandelion in Ohio?

B. KENYON.

Oakland, Cal., Apr. 15, 1887.

Friend K., your question is hard to answer; but if an acre of dandelions would furnish as much honey as an acre of alsike, I would suggest estimating ten colonies to the acre. In that case you would want ten acres of dandelions. As cultivated dandelions are now receiving a good deal of attention, especially in the east, the time may come when we shall have ten acres in one locality; but where they are raised for greens, for table use, I believe they never let them come into bloom. I think bees work on dandelions about two weeks with us. They commence blooming heavily about the first of May.

EXPERIENCE WITH CYPRIANS.

My experience with Cyprians is so much like that of Mr. Abbott, as given on p. 303, that I am surprised that they should be recommended as superior or even equal to the Italians. My first experience with them, when they were merely a nucleus, was very satisfactory, and I was inclined to praise them on account of the prolificness of the queen; but as they increased in number, so the trouble in handling increased also, until they were nearly unmanageable. I put on a lot of empty combs and let them completely alone until almost winter; and, being so extremely ill tempered, they were not prepared as usual, and nearly died. However, they soon became as populous as ever, and were a source of annoyance another season, at the end of which the colony was requeneed, and that with more difficulty than any previous manipulation. The principal reason that I kept them so long was on account of the prolificness of the queen; yet they did not gather any more honey than other colonies, I believe; and, not being accustomed to a veil, and seldom having one without holes, I dreaded to have any thing to do with them. My last veil had a window in which broke out, and I have not yet sewed the hole shut.

CHRISTIAN WECKESSER.

Marshallville, O., Apr. 19, 1887.

Every boy or girl, under 15 years of age, who writes a letter for this department, CONTAINING SOME VALUABLE FACT, NOT GENERALLY KNOWN, ON BEES OR OTHER MATTERS, will receive one of David Cook's excellent five-cent Sunday-school books. Many of these books contain the same matter that you find in Sunday-school books costing from \$1.00 to \$1.50. If you have had one or more books, give us the names that we may not send the same twice. We have now in stock six different books, as follows; viz.: *Sheep Off, Silver Keys, The Giant-Killer, or, The Roby Family, Rescued from Egypt, Pilgrim's Progress, and Ten Nights in a Bar-Room.* We have also *Our Homes, Part I., and Our Homes, Part II.* Besides the above books, you may have a photograph of our old house apiary, and a photograph of our own apiary, both taken a great many years ago. In the former is a picture of Novice, Blue Eyes, and Caddy, and a glimpse of Ernest. We have also some pretty little colored pictures of birds, fruits, flowers, etc., suitable for framing. You can have your choice of any one of the above pictures or books for every letter that gives us some valuable piece of information.

CONDUCTED BY ERNEST R. ROOT.

TRYING THE WINDMILL.

LET me see; I believe we left Jimmy and Sam starting off to school, lamenting because they had to go. They argued that nothing would be lost if they stayed out only *one* day. As they had been at school so steadily they knew that the final examinations could not possibly show it. I presume they did not think that final examinations were not the only things they went to school for. Mrs. Green could have told them that it is the every-day attention to regular duties that makes success in any department of life, and that boys who go to school every day in the year, when school keeps, unless sickness or something else of a serious nature prevents, are the boys who, when grown, make the most successful men, as a rule.

Our young mechanics, however, were not inclined to take a very philosophical view of things. They finally reached school and got into their seats just as the last tap of the bell announced that school had begun. They took their books out, laid them on the desks and tried to study, but their minds were on the grindstone and windmill. At recess, as usual, there was more speculation among the boys in regard to the windmill. Jake insinuated, once or twice, that "twouldn't last long;" but the two had so much confidence that it *would* last, that they did not pay much heed to the remarks, which savored strongly of Jake's jealous disposition.

After school was out, Jimmy and Sam hastened to their windmill. On their arrival home, Mrs. Green asked Sam if he would not go up town and get some tea—they were entirely out, and would need some for supper. Sam was not at all willing to comply with his mother's wishes, but said they could "get along without their tea." He meant no disrespect by it, but said it in such away that it was evident he thought the windmill was of vastly more

importance than tea, supper, or any thing else. Very fortunately for Sam, at this juncture Jimmy's little brother Ted happened over, and the boys very speedily made a bargain with him, by which the youngster was to receive a whole cent for getting the tea and bringing it home. The boys then started toward the scene of the windmill. It was not revolving as fast as it was in the morning, and it was squeaking. It was but the work of a few moments to get a little lard and apply it to the wooden bearing. It then revolved to the boys' great satisfaction. After a good deal of fussing they finally got their grindstone connected with the seat of power by means of the clothes-line. The grindstone immediately commenced revolving, and a more intensely pleased couple of boys you never saw. They found one trouble—that the clothes-line would keep running off; and in spite of all the two windmill-builders could do, they could not make it stay on. Just before supper Mr. Green was called upon to assist. He explained to them how the grindstone was "out of line" with the drive-wheel of the windmill. A very little adjustment fixed it so that the clothes-line held its position on the wheel. Mr. Green, as he witnessed the grindstone revolving, now expressed some feeling of satisfaction, and even became enthusiastic. Just at this moment his wife called out that supper was ready, but he was so intent that he begged they might be excused for just a few moments more. An ax was soon applied to the stone, to be ground, but the mill was hardly adequate to the work. On going to the barn window they discovered that the little breeze was dying down, as it is apt to do in the evening; but the boys said their machine was "doing well enough;" and that, when there was a good stiff breeze, they would have "lots of power."

That evening, after supper, Mr. Green offered to purchase for the boys a light-running saw-arbor in consideration of their making the windmill run successfully. A careful inspection of the price list from the Home of the Honey-Bees showed that a mandrel could be had for the small sum of \$2.25. Mr. Green told the boys that they would also need a couple of thin saws. The order for all was duly made out and sent. After Jimmy had gone home, and Sam was just crawling into bed, he thought he heard a noise in the back yard, out by the barn. It sounded as if some one were throwing stones. Sam poked his head out of the window, and listened; but every thing seemed perfectly quiet. Remembering his previous experience, and how the moon had made fun of him the night before, he crept back to bed, and knew no more till daylight.

The next morning, just as he was going toward the barn, Jimmy followed him up. On looking toward the windmill the two were thunderstruck, not to say amazed—two of the fans of their windmill had gone, and the tail was split! "Surely," said Sam, "there was no heavy wind last night—what could have done it?"

"I know," growled Jimmy; and his face began to flush with anger; it was the work

of that good-for-nothing lazy pup of a Jake. I just *know* he done it."

"That's so," said Sam. "We will fix him for that. What a mean trick that was! Just because we are successful in making it go, and were having so much pleasure from it, he has got to go and spoil it all."

Sam was so angry and hurt that tears began to trickle down his cheek. Just then Mr. Green made his appearance. On seeing the windmill, and on being told who the probable malicious perpetrator of the mischief was, he cautioned the boys, saying that they were not *sure* that Jake did do it—that they had no positive evidence of any one doing it.

"But," said Sam, "I feel pretty sure now, that I heard some one throwing stones just as I was going to bed last night. I concluded then that it was my imagination, and gave no further attention to it."

"Are you sure," said Mr. Green (seeming not to have heard Sam), "that you fastened those wings to the mill securely? Are you sure that you did not leave out some of the screws?"

Jimmy and Sam were both positive that they had made every thing very strong. Although Mr. Green in his own mind felt satisfied that some person very maliciously inclined had endeavored to vent his spite on the two boys, he tried to dissuade them from taking this view of things. The boys, on the contrary, felt confident, and they determined that they would sift the thing clear to its very depths. Said Jimmy to Sam, after Mr. Green had left them, "I tell you, Sam, we won't say any thing about this 'ere thing at school. We'll fix the mill as soon as we can this morning, and pretend that nuthin' unusual has happened. In the meantime we'll tell Frank the whole business, and let him ask around, kind o' still like; and if he finds out sure that it was Jake, we'll give him the worst old pummeling he ever had in his life."

"Yes," said Sam, "and every fellow at school will side in with us—won't they?"

Continued June 15.

JUVENILE LETTER-BOX.

"A chiel's amang ye takin' notes:
An' faith, he'll prent it."

A YOUNG BEE-KEEPER.

I have a swarm of bees. They are in a thin-walled hive, packed with hay. Last summer we had 87 swarms of bees in the spring. We increased them to 100, and got 4530 lbs. of honey. My swarm made over 50 lbs. I am going to stay at home from school this summer to help take care of the bees. We have 40 strong swarms now, and 22 weak ones. All but mine and two other swarms are in chaff hives. A neighbor of ours was going to kill a swarm of bees for the honey (about 6 lbs.), and father gave him 6 lbs. of section honey for them. They are the strongest swarm in the yard now. In the fall we go to each hive and take out three frames from the strongest, and four or five from the weakest hives, and feed back the honey. The main dependence for honey here is white clover and basswood. When

we work with the bees in warm weather I do not wear any shoes or gloves. We made 32 new hives last winter, and I helped saw the boards and nail them up.

PRYER LINDLEY.

New Providence, Iowa, Apr. 2, 1887.

BEEES AND CARP-PONDS.

We had about 40 stands of bees last spring. They gained up to about 80 stands. We extracted six or seven barrels of honey, and got a few hundred pounds of comb honey. Our bees wintered outdoors last winter, with two or three thicknesses of cloth over them. This spring there were 41 stands left. I think a person can get more extracted honey from strong swarms in large hives.

Summer before last we made a carp-pond. It is about ten rods long and four or five rods broad. It is 4½ feet deep at the south end, and gets shallow gradually to the north end. The next fall father put 16 German carp in the pond. In the spring we let the water out, and the fish were about three times as large as they were when they were put in. Last summer we made another pond. It is about 8 rods long and 4 or 5 rods broad. It is about 8 feet deep at the south end, and 4 at the north end. We put 46 young carp in our ponds last fall. We have not let the water out since last spring.

Falls City, Neb., May 1. ALBERT B. WILTSE.

AN INCUBATOR; HOW IT WORKS, GRAPHICALLY DESCRIBED BY A LITTLE GIRL.

Pa has started poultry-keeping. He made two incubators, and filled them with eggs. The first one did not hatch, but the second one hatched well. You don't know how funny it looks to see chickens hatching in such a box; but I tell you it is a pretty sight. Pa made a brooder to put them in. I wish you could see them when they are eating. We have three good-sized boxes for them to eat in, and they fill them up too. They are the prettiest when they are eating, for they seem to be so well pleased. I like to see any thing mirthful, and I like to be so myself. The last two or three that hatched were cripples, and the other ones trampled them under foot. I could not bear to see the innocent little things hurt, so I wrapped them in a cloth, and once in a while I took them out and fed and watered them. I do not know whether I can raise them or not, but I will try my best. Pa is going to make a large brooder to put our little pets in. He has built a house to put them in, and I shall be glad of it too, for they are so noisy in the kitchen. They pick each other's eyes. Sometimes they go blind, and if we grease their eyes with tallow they come open again.

CLARA STREBY.

Paw Paw, W. Va., April 4, 1887.

HOW PAPA CHASED AND CAUGHT A SWARM.

Once when pa was coming home in the afternoon he heard a swarm of bees. He started after them, and they came past the house where we live. Mamma heard them going by, and when she looked down the road she saw pa coming up as fast as he could come, his heels flying as high as his head. When he came to the house, mamma asked whose bees they were. Pa said, "They are mine if I get them," and off he started up through the town; and when he came to the square, one side of the street was lined with people, so he came back to the house and got a box, and put them in. It was a very big swarm. We got 50 lbs. of honey from the old swarm. Pa has the boxes about 6

inches from the ground. He has fixed cinders around the box. He thinks that sawdust is not very good, as it draws the ants, and cinders, if any thing, keep them away. Mamma and I tend to the bees while papa is away. CORA FRITZ, age 12.

Marshallville, O., Mar. 18, 1887.

A QUEEN-BEE IN A RUBBER BOOT.

My pa has 26 colonies of bees, and he lost only one through the winter. He wintered them in chaff hives, and on their summer stands. One time he was hiving a swarm, and when he came down to the house he pulled off his rubber boot and found the queen in it. She looked discouraged. We put her back in the hive. ARTHUR STILES.

Deposit, N. Y., Apr. 30, 1887.

It was a little remarkable that the queen should get into the rubber boot, and still more so that she wasn't killed, friend Arthur.

THE LITTLE BEE: COMPOSED BY A JUVENILE.

There is a little traveler
Which travels many miles
O'er many a wood and meadow,
And sucks at flowers and spiles.
For he is called the honey-bee,
Which travels many a day,
And gathers nice sweet honey
Through all the sunny May.
This bee works hard on basswood,
From the bottom to the top,
And works on buckwheat also,
All o'er the farmer's crop.
And he works the summer long
Through all the trees and dale;
He can not work, however,
Through wind and stormy gale.
This little traveler worketh
Till his wings are worn away,
And in the frosty weather
This bee shall pass away.

O. A. BURNETT, age 14.

ALICE'S POETRY.

I have seen in your journal that any little girl who would write a verse or line about bees would, in return, receive a book. Here I will write a little verse about bees.

Oh the bee, the pretty bee!
As it flies through the fields,
Sipping honey from all the flowers,
And it never troubles any one as long as it is left to itself;
But if it is bothered, then look out for an angry blow.

ALICE E.

Well, Alice, I am afraid there is not much real poetry in your lines. Your sentiment is good, and you started out very well; but somehow in the rest of the lines you forget all about rhyme or meter. If you do not know what rhyme or meter is, ask your teacher.

HATTIE'S LETTER.

I wrote to you in 1884, and I saw my letter in print. It did me so much good, I believe I will write again. I think that a great many people take your good book. After I wrote before, I got more letters from bee-men; and the funniest of all was a letter saying, "To Hattie Hall, Esquire." Mamma and papa laughed heartily. I always imagined I should like to live with you, because you are so much like a preacher. My desire is to live with a preacher. We have a good Sunday-school and prayer-meeting here every Sunday. We have a Baptist and Methodist church here. I have two brothers and three sisters. My two oldest sisters are off at school. HATTIE HALL, age 13.

Sparta, Miss., March 24, 1887.

HOW ALICE HIVED A SWARM.

My aunt was sick, and papa and mamma went to see her. While they were gone the bees swarmed and settled on a peach-tree. I thought I must hive

them, or they would be lost. I took a little table and set it under them and went into papa's work-house and got a hive and put it on the table and got some water and sprinkled on them. I jarred the limb so as to get them on the table, and when they were on the table I sprinkled some water on them, and they went in nicely. I got but one sting, and that was between my eyes. It caused my face to swell so that my eyes were nearly closed. Papa said I did well for the first time.

Buntyn, Tenn.

ALICE NORRIS.

FEEDING BEES WATER BY THE AID OF CORNCOBBS. JAPANESE BUCKWHEAT.

Papa's bees are doing well. He received some buckwheat from you yesterday, and he thinks he will have him a nice patch of it for his bees. Those buckwheat-seeds looked just like beechnuts in Tennessee, only they are a great deal smaller. I have a pretty rose-bush in papa's bee-yard; and when I go to get a rose a bee stings me, and I hardly ever get a rose for I had rather do without one than to get a sting. It has not rained here in a long time. The bees are going everywhere to get water. Papa fixed a trough and put cobs in it to hold water for them cobs hold water better than any thing else that we know of. We have to fill it up every day. I have written two letters before this, and got a book, but I don't expect to get another one this time, for I don't know any thing new.

MATTIE F. DILLEHAY, age 13.

Milford, Texas, April 6, 1887.

A COLONY THAT TRIED TO SWARM ON FOURTEEN CONSECUTIVE DAYS.

Pa has 110 stands of bees in the cellar. He sold about half of them at our sale last fall, and keeps them till April 15th. Last summer pa had one swarm that came out nearly every day for fourteen days. He kept the queen-excluder on the entrance. He wanted to find out if the bees would finally kill their mother for not going along with them, but they did not. He finally hived them with their queen, and then they went to work in earnest. All the fourteen days they were swarming they gathered but little honey. CLINTY BRUBAKER.

Maxwell, Story Co., Ia., March 29, 1887.

Thanks, friend Clinty, for so carefully giving the results of your father's experiments. The incident which you give is most remarkable, and I wonder that the bees did not become disgusted with their queen and kill her. I think, however, that, as a general rule, where the perforated metal is kept over the entrance, and the bees swarm two or three times in succession without bringing the queen with them, they will finally kill her and raise another in her stead. After the swarm has come out once, I believe I would catch the queen and place her among the flying bees before the swarm returns, and you can then hive them where you wish.

BEES IN CELLAR CONSUMING LESS STORES; RUTH'S BIG COLONY.

We had 23 colonies at the beginning of winter, and we have lost only two so far. For the first time we wintered four colonies in our cellar, which has a cement bottom. I helped papa carry them out of the cellar yesterday morning; and when he opened one hive there was but an ounce of honey in the frames, and no brood or eggs. At noon, when he looked into the hive, the queen had begun

to lay. Excepting this one colony, those that were in the cellar were stronger colonies, and had not consumed so much honey as those out of doors. Last summer, during swarming season, a swarm came out and alighted on a currant-bush. While papa was getting ready, another swarm came to the same place; and, while putting them in the hive, a third swarm came and went in with them, making such a large swarm that papa had to put on another story, and could hardly carry it to its place on a wheelbarrow. RUTH WAITE.

Hinckley, Ohio.

That bees in cellar do consume less stores than those out of doors is generally admitted. It is not always the case, however, that cellar-wintered colonies come out stronger.—Those three swarms must indeed have made a rousing big colony.

BEING TRUE TO OUR NAMES.

Pa says his first number of GLEANINGS and the "first boy" came to his house about the same time, so I was named after you. I will try to live so as to be worthy of your name. I have never used any profane language, and never will, and wish all little boys would try to do the same. I never tell my ma that I "won't," or "don't want to," when she asks me to do any thing, for she is kind to me, and I intend to be obedient, and help her all I can.

I have split and corded ten cords of wood in the last two weeks, besides having lots of time to play. Roy Gift helped me two half-days. Ma said she would get me a new illustrated Bible as soon as I got the New Testament read through. I mean to read four chapters every day, but once in a while I forget it. The bees are in the cellar yet. Pa says there is only one colony dead out of 130. He is anxious for the weather to get warm, so there will be something for them to do, then he will put them out. He says he has learned by sad experience that bee-keepers generally put their bees out too early in the spring for this climate.

We got 40 eggs from 67 pullets yesterday. They will lay about 90 dozen this month, and did lay about 60 dozen last month. I heard pa say he thought that bees that were about one-half Italian and one-half black, and chickens half Brown Leghorn and half Plymouth Rock, were the best bees and chickens for business. ERNEST GILL, age 10.

Star, Vernon Co., Wis., Mar. 27, 1887.

You must indeed be a dutiful son. If the name "Ernest" implies all you think it does, and all you live up to, I must confess that I have not been as "Ernest" as you. I would that all our little juveniles might try to live as you do. The boy who makes the Bible his companion, as I think you do, could not well be otherwise than "earnest" in the sense which you give to it.—In regard to taking bees out of the cellar too early in the spring, I would say that your papa has come to the very same conclusion that Dr. Miller has.

HOW CHARLIE MADE TWO DEAD COLONIES COME TO LIFE.

My father has 36 swarms of bees now. I have 3. The first one of my swarms was short of stores in the fall, so I watched them. One morning I went out and they were dead. I brought them in the house and told mother to make some honey syrup. She took some candied honey and a little water, and put it on the stove till the honey was all dissolved.

I then took it outdoors to cool a little. When it was about as warm as new milk I opened the hive, took out the combs with the dead bees, and poured the warm syrup right on the bees and combs, put them back in the hive and shut it up, nailed some wire cloth over the entrance, and set them down by the fireplace. In less than an hour they were cutting at the wires, and had raised a great hum. I then put them upstairs, and gave them a chunk of honey that came out of a bee-tree which we found in the mountains, this being January 10, 1887. Jan. 15th I found eggs and small larvæ. Jan. 20th I put them back on their summer stand. March 1st they commenced bringing in pollen, and they are doing nicely.

A DISABLED QUEEN THAT IS STILL A GOOD LAYER.

I have another swarm of bees that I bought of my father, Feb. 1, 1887, he supposing they were dead. I told him I would give 25 cents for the bees and queen. He said, "All right." But they were not dead. I transferred them into one of my hives. The queen has both of her hind legs and her left middle leg injured in some way, so they are of no use to her; but she is one of the best layers I ever saw.

In the fall I had 5 swarms of bees, but now I have 3. I had one lose its queen, so I put 2 swarms into 1.

We have flowers here the last of February, generally; but this season there were no flowers till March first.

The apple-trees are in bloom. The apple-blossoms came out April 5th; peach-blossoms, April 10th; strawberry, April 10th. All the summer birds are here but orioles and wild canaries. Honey is selling at 12½ cts., extracted; comb, 15 cts.

If you wish, I will send cuts of my hive and my way of feeding out of one hive into an other kind of hive.

CHARLIE H. STEWART.

Altona, Col., April 17, 1887.

Many thanks, friend Charlie. You have unconsciously struck upon the same point suggested by Wm. C. Greer, in the Juvenile Department, page 311. I would advise you to carefully read the answer, and see if it does not confirm some of your experiments. The point you bring out is a good one; that is, we must not be too hasty in pronouncing a colony dead, even though it has every appearance of being so. You seem to have been a little wiser than your father, but it is not very often that boys have more wisdom, though they sometimes think they have. Twenty-five cents is pretty cheap for a whole colony of bees, is it not, even if they are apparently dead? but twenty-five cents would be a rather dear price if you found that it was impossible to revive the bees. Another thing, Charlie: You have given us proof that a queen with both of her hind legs disabled, and a middle leg besides, is a good layer. I am glad of this, for sometimes the legs of queens get injured in transit through the mails, and customers are inclined to kill them without even giving them a trial. Don't discard any queen, friends, until you know by actual test that she can not do good work.

ANOTHER JUVENILE INVESTMENT IN BEES.—HOW \$1.50 WAS MADE TO BRING \$8.00.

A year ago last summer I picked berries. Papa paid me the same for picking that he did other boys and girls, so in the fall he said I had better invest

part of my money in bees. He said he would sell me a nucleus for \$1.50. I put it in the cellar myself, and in the spring it was a nice little swarm. Papa gave me a hive, and hung the frames in it, and put in the division-board to shut them down on just as little space as they could occupy. I put a feeder on top, filled with extracted honey. When they increased so they needed more room I put in a frame of foundation. By the time the honey-season commenced I had a full swarm. I then put on the sections. When one set was full I took them off and put on another set. My racks hold two sections, which weigh $1\frac{1}{4}$ lbs. each. I sold my honey to papa for \$8.00. He has 440 stands. My brothers Willie and Ernest will each tend an apiary in the country this summer, and I will help papa in the home apiary. I cage queens for papa, and help take off honey, and take it to the honey-house. I am not going to let mine swarm if I can help it, for it will make more money if it does not.

I am 11 years old, but I started in the bee-business when I was 9 years old. RALPH BALDWIN.
Independence, Mo., Mar. 31, 1887.

Well done, friend Ralph. You started from the very bottom, without even *borrowing* money. By the conditions of the promise on page 226, I think you are fully entitled to the chromo, so we send you one. We will say again, that to all boys and girls who will do as well with *their own* bees, a chromo is waiting. Let us hear what you have done.

TOBACCO COLUMN.

PROF. COOK JOINS US IN URGING WARFARE AGAINST TOBACCO.

EDITOR GLEANINGS:—I wish to express my pleasure and gratification in view of the statistics which D. E. Brubaker gives in last GLEANINGS, p. 313. Just to think of 446—and, of course, as you say, that is but a fraction of the whole number—of permanently reformed smokers, or users of tobacco. Just to think of the useless waste saved; of dirty men made clean; of suffering households made happy; of disease-germs uprooted; of a great public nuisance in part, at least, abated! To be the instrument of such a blessed consummation is a glory to a man, and I congratulate you most heartily. When we think that more than half a billion of dollars is spent each year by our countrymen in not only a useless but a pernicious habit, and often when these very dollars are imperatively needed to give a family the bare necessities of life, no wonder we envy you your good and blessed work. When we consider how many men are steeped in the not only foul but seriously poisonous emanations of tobacco smoke, whose very presence makes rank the air of car or hall, what wonder we wish we had your power to convince men that there is a better way. As we remember the good wives and mothers who daily pray that their children may be kept from a dreaded habit in spite of inherited tendencies and degrading example, we pray that we too may be helpful to men, and may also aid to stay or cure the evil habit. When we note dread and may be fatal disease, the direct offspring of the tobacco habit, claiming victims each year, and these victims so enervated that

they are powerless to say no, when they know that "no" means life and "yes" death, what wonder that we are enthusiastic in our admiration of this part of your work.

We are having frightful examples each year of persons—especially young persons—who are so diseased from excessive use of tobacco, that physicians direct the total cessation of the use of tobacco as the only hope of cure. Often such persons are so enslaved, or have so lost their will power, that to stop is impossible—at least practically, for they do not stop. I have known several such cases, and yet the great army of boys—mere nurselings—that is constantly being recruited is almost disheartening.

Mrs. Axtell touches a still more serious aspect of this tobacco problem, when she intimates that the use of tobacco opens the door to the saloon. Oh, yes! we may even go further; these two join to lead the unwary to the third great evil which is sapping the very virtue of our people, and whose end is death. Said an honored State Senator to me a few years ago: "I am glad you work to keep our boys from the use of tobacco," though he used it himself. Said he, "Tobacco conducts to the saloon, and the saloon points to the way that leads down to death." Can any one doubt but that his suggestion was founded in fact? Many stop at the pipe; many halt at the saloon; many take the last fatal step, and leave virtue and manhood behind. Go on, Mr. Editor, in your effort to check the evil in the bud, and may God speed the work.

A. J. COOK.

Agricultural College, Mich., Apr. 27, 1887.

I have used tobacco for three years. I quit about three months ago. Will you please send me a smoker? If I ever use tobacco again I will pay for the smoker.

ALFRED S. VANSYOC.

Indianola, Iowa, March 16, 1887.

I have used tobacco for nearly 25 years, and have left off its use, and will never touch, taste, or handle it again; and if I do ever use it again I will pay for the smoker.

MILO GEORGE.

Bowling Green, Ohio.

I hereby promise not to use any tobacco in any form in the future, if you will send me a smoker. If I break my pledge I am to pay you for the smoker. I was a smoker of cigars.

S. H. ZEIGLER.

Mulberry, Pa., March 29, 1887.

I wrote you a letter some time ago, and inclosed 20 c. to pay the postage on a smoker for Mr. Braun, of Kilmanagh. He promises not to use tobacco again; and if he does, I will pay you for the smoker.

F. C. SMITH.

Kilmanagh, Mich., March 25, 1887.

I understand you offer to any man, who will stop using tobacco, a smoker. I will comply with those terms. I make the regular promise, that, if I ever commence using the weed again, I will pay you for the smoker.

A. WILBUR.

Scribner, Neb., March 21, 1887.

I have used tobacco for 15 years; but in February last my father-in-law and I resolved to quit using tobacco. If I am entitled to a smoker, send it along; and if I ever use the weed again I will pay you for the smoker.

J. C. HALL.

West Liberty, Iowa, Mar. 30, 1887.

I have used tobacco for eight years, and I hereby pledge myself to the usual promise.

Prattsville, N. Y., Apr. 10, 1887. C. E. CONINE.

I have quit the use of tobacco in all its forms. Please send me the smoker; and if I commence again I will send you the full price for it.

S. W. DUCKWORTH.

Ritchie C. H., W. Va., March 18, 1887.

Having quit the use of tobacco in all of its forms, I wish to pledge myself never to use it again. Please send me a bee-smoker; and if I ever use tobacco again I faithfully promise to pay you for it.

England, Pa., Mar. 11, 1887. S. B. POST.

I am glad to say I have stopped the use of tobacco entirely, and hope nothing will make me take to using it again. If you think me entitled to a smoker, please send me one; and if I return to smoking I will send you the price for the same.

Abbeville, S. C., March 13, 1887. D. W. THOMAS.

I have recently quit the use of tobacco, partly through the influence of GLEANINGS and partly because I found it to be injurious to me. If you think I am worthy of a smoker, send me one and I will pay for it if I ever use tobacco again.

JOHN FRANKLIN.

Round Rock, Texas, March 14, 1887.

My father quit the use of tobacco after using it many years. The last time I saw him smoking was some time last summer. If you send him a smoker he will pay you for it if he ever uses tobacco again. He is 76 years old, and has 15 swarms of bees.

J. S. NORTON.

West Ferndale, Wash. T., Mar. 8, 1887.

Miss V. M. Smith, through the influence of GLEANINGS, has been induced to give up the use of tobacco, and requests me to ask you to send her a smoker, for which she agrees to pay if she uses tobacco again in any form.

D. W. MOSS.

San Augustine, Texas, Mar. 29, 1887.

A CHEWER FOR 45 YEARS.

I have been chewing for about forty-five years. Last November, about the 18th, I quit chewing. If you think you can send me a smoker, I shall be much obliged to you; and if I commence chewing again, I will pay you full price for it.

Lectonia, O., Feb. 21, 1887. J. BRINKER.

I am a reader of GLEANINGS. I have been a chewer of tobacco almost from childhood. I have made a solemn vow never to use it again. I have bees; and if you think I am entitled to a smoker, please send it, and I pledge myself to you that, if I ever use tobacco in any form again, I will send you the price of the smoker.

J. B. MOUR.

Lafayette, La., March 12, 1887.

My son-in-law has used tobacco 24 years, and I have tried to get him to stop its use, but all in vain. I saw in GLEANINGS that you were giving smokers as a premium where they would abstain from its use. I went at him again finally, and have succeeded in getting him to promise. If you would send him a smoker, he would stop its use. He hasn't used any in 3 or 4 weeks. If he ever uses it again he says he will pay for the smoker; and if he doesn't, I will if I am living. But he is an honest man, and will pay it.

R. H. ALLEN.

St. Louis, Mich., Feb. 14, 1887.

AN INJURY TO THE HEALTH.

I have been in the habit of smoking, and do believe it to be an injury to my health. If you feel willing to send me a smoker by mail I will give you my word that I will not use tobacco any longer in any way. I am not saying this merely to get a smoker free, but I mean all I say.

Cleveland, Ga., Feb. 12, 1887. J. C. KENIMER.

A BINDING PLEDGE BETWEEN HUSBAND AND WIFE.

I have been a reader of GLEANINGS for seven years, and have read every word of every number that I have received. I have been trying to get my consent to quit using tobacco ever since I read your first number. I have been praying over the matter, so the other day my good wife said to me, that if I would quit the use of tobacco she would not use any more snuff, so I accepted her proposition, and expect, by the help of God, to keep my promise. Now, if you are willing to send me a smoker you can do so; and if I ever commence the use of tobacco again I will pay you for it.

Covington, Ga., March 21, 1887. J. F. MCCORD.

ABRUPTLY QUIT.

I see that you offer a smoker as a premium to any one who will abandon the use of tobacco. I have been a slave to the use of tobacco for 15 years, and it is injurious to my health. Your offer has induced me to for ever abandon and abruptly quit the use of tobacco in any form. Now, as I am beginning to raise bees to some extent you will please send me a smoker; and I solemnly promise that, if I ever take up the use of tobacco again I will pay you the full price for the smoker. I am responsible for what I say.

B. G. LUTTRELL.

Luttrell, Ala., Mar. 1, 1887.

QUIT PAYING THE NATIONAL DEBT BY GIVING UP TOBACCO.

I take great interest in reading GLEANINGS. I have read and re-read your A B C book until I have it almost learned by heart; but I have had bad luck with bees this past winter. I lost five out of twelve.

I think that I am entitled to a smoker, because I was one myself for 27 years. I smoked in that time about 700 lbs. of tobacco, and the U. S. internal revenue on the same has been quite an item in the reduction of the national debt. I would as soon go to the gallows as to commence smoking again, as I find that I feel much better than I did when I smoked the filthy weed.

S. W. TAYLOR.

Harveyville, Pa., April 5, 1887.

A LETTER FROM ONE WHO HAS INDUCED THREE OF HIS FRIENDS TO GIVE UP TOBACCO.

I have a young friend who is becoming somewhat interested in bee-keeping, and I told him you would give any one a smoker who would quit using tobacco, and promise not to use it again. He says he will promise to quit, and will not use it any more; and if he should he will pay for the smoker. Please send him one, and I will vouch for him. He makes the third one who, with your help, I have induced to quit using the vile weed, and they have so far stuck to their promise. I am always on the watch to induce others to quit using whisky and tobacco, as I think they are two of the worst habits a man can contract.

C. W. PLENT.

Stanton, Ala., March 21, 1887.

Many thanks, friend P., for so kindly helping along the work in the Tobacco Column.

OUR HOMES.

Blessed are the pure in heart; for they shall see God. —MATT. 5: 8.

BEFORE I tell you of my very pleasant visit to Professor Cook and his family, I want to say that it has been characteristic of the professor to rebuke gently but firmly every thing in the line of which I talked to you in *Our Neighbors*, in the last issue. The first time I ever met Prof. Cook, or, at least, the first time I ever had a chance to have any confidential talk with him, was when we visited an old bee-keeper in the neighborhood of the Michigan Agricultural College. In telling something, I related a common phrase of expression. He stopped right in the road to give emphasis to his remark, and asked me if it would not be better to forbear making such speeches.

"But," said I, "it is the truth, is it not?"

His reply was something like this:

"Mr. Root, it may be true; but even if it is, I don't believe it is best to speak it. If we do every thing in our power to encourage the idea that the world is not depraved and low-minded, will it not help the world to be better?"

His talk was, in effect, something like this: If you tell a boy he is a thief, and that you don't expect any thing better of him than a thievish disposition, you help on in that very line. If you tell him you have confidence in his word, and are not afraid to trust him (within the bounds of reason, of course), is it not true that the chances are greatly in favor of helping the boy to be a good deal better boy? Well, a great many times when we shock people by telling something very bad, we reply, "Why, is it not true?"

Now, I heartily agree with Prof. Cook, that the truth in such cases had better not be told. When I sat in the hotel and listened to the indecent talk of those two young men, my mind reverted to Prof. Cook, and I wished that he were there with his weight and influence, and especially his kind, genial way toward sinful humanity, to rebuke these boys in a way that would do them good. May be he would have had to give up the task and take another room as I did; but I do know, however, that he has all his life been in the habit of rebuking faithfully and fearlessly friends and foes alike, whenever they need reproving and rebuking.

I hope the professor will excuse me for relating one little circumstance; and if I don't get it just as it actually occurred, it will be near enough to carry the moral with it.

In his younger days he was once called upon to ride in a stage-coach with quite a lot of distinguished men—members of Congress, and others who stood high in office and in places of trust and intelligence. They began indulging in impure jokes and talk, of which they should have been ashamed. He bore it for a time, but finally ventured a remonstrance. There were so many of them, however (and he was then only a boy), that they tried to turn the joke

back on him. He finally told them firmly that he would stop the driver and get out unless they would stop the kind of talk they had been indulging in. One of them remarked, "If the boy can't stand it, let him get out." If I am correct, the driver was told to stop. When he asked what the matter was, our young college student told him he wished to get out and go on afoot, unless he could have a guarantee from the gentlemen present that the kind of talk they had been indulging in should be stopped. By this time some of the better ones began to come to their senses; and one who had weight and influence declared that the boy was right, and desired the driver to go on, saying that he himself would guarantee that there should be nothing more improper or out of place.

Friend Cook, in speaking of it, said that, when he was a boy at home on the farm, one of the rules that he had laid down himself was to say nothing or do nothing under any circumstances that he would not say or do in the presence of his mother; and when he became a married man, and had a queen of his own to rule his household, he decided that nothing should pass his lips in her absence that he would not say in her presence. And in all my acquaintance with him I can not remember that I ever heard a speech or word that he would hesitate to speak, were she or their two children present.

I have spoken to you many times lately, dear friends, about being acquainted with people, and it has lately occurred to me there is many times great need that fathers and mothers should be acquainted with their own children. Well, the acquaintanceship with different members of the family in Prof. Cook's household is closer and warmer than in any other family relationship I ever saw before. Not only are the husband and wife one in every sense of the word, but the children, Bertie and Katie, are one with father and mother. Papa and mamma share all their plans and pleasures and tasks, and the children, too, know all about papa's and mamma's work. Young as they are (about ten and twelve, if I remember rightly) they are prepared to understand and commend almost any able effort their father may make in his literary work. They share with him most fully in his labors for the uplifting of the people. The sentiment of this entire household seems to be a hungering and thirsting after righteousness; and their lives seem to be a prayer that God's kingdom may come, and his will be done on earth as it is in heaven.

In the *Home Papers* of a month ago I spoke about letting the children get acquainted with the neighbors' children, even if the latter were not all they ought to be, and one of the friends has taken me to task for so doing. I did not talk with Prof. Cook directly in regard to this matter, but I am pretty sure he agrees with me in the effort to have our children brought up so as to be pure in heart, according to the text at the head of this talk. I think we should be careful about going to such extremes that they know nothing of the evil that is in the world; yet I would by no means go so far as

some recommend, and push the children needlessly into scenes of vice and sin, but I would endeavor to so fortify them in the home circle that they may go safely wherever it may be convenient to have a child go. There are parents here in Medina who have kept their children away from school because of the bad boys and the bad talk they learned at school. Now, I think they made a mistake. Sooner or later every boy and girl is obliged to meet more or less evil. I should say, let them meet it when it can not well be avoided; but prepare them for it beforehand, and strengthen them during the trial. Tell them of the responsibilities that rest upon Christian people; tell them of the great harvest, and of the comparatively few laborers. Pray for them as Christ prayed for his own when he said:

I pray not that thou shouldst take them out of the world, but that thou shouldst keep them from the evil.—JOHN 17:15.

Bertie and Katie are by no means ignorant of the great problems that lie before us as a people and as a nation. On our way (from Owosso to Lansing where Prof. Cook's farm and sugar-bush are), something occurred to illustrate this. We were riding on the cars, and a drunken man took a seat right back of Mrs. Cook. As the cars were crowded, our little band was somewhat separated. The drunken man commenced to utter oaths and blasphemy; and as no one noticed him he finally proceeded to obscenity. Prof. Cook has decided, as I have, that it is useless to talk to an intoxicated man. You might as well try to remonstrate or reason with the father of evil himself. Mrs. Cook was obliged to take another seat. This crowded a little upon a couple of fast young men. They occupied one seat while their overcoats and luggage were in the one opposite. In answer to Prof. Cook's inquiry, they replied that the seat containing their luggage was occupied, giving him to understand that somebody else had the seat who would be in presently. I saw their trick, however, and so did the professor.

"My friends," said he, "you are entitled to the seat you are sitting on, but not to this other one. I know my rights; and if you mean it is occupied because it contains your luggage, I shall have to ask you to vacate it."

He said this firmly, but with perfect kindness. One of them finally rose up, with the remark, "Well, now look here, friend; if you won't get into a passion we will give you *both* seats."

The remark about getting into a passion was entirely uncalled for, as Prof. Cook did not show the least trace of disturbance of any kind. While he calmly assured them he never got into a passion at all, one of them remarked:

"We will take our cigars, and go into the smoking-car; and when we have smoked three or four cigars apiece, and have had a couple of glasses of brandy, we shall be in just the trim to deliver a prohibition lecture to these people, if they want one."

As he spoke I caught sight of a flask of some kind of liquor in the side pocket of one of the overcoats. The young men by some

means correctly inferred that our little party were of the class who accept the promise in our text, to those who are pure in heart, pure in speech, and pure in their habits. The last speaker, thinking he had said a funny thing that ought to be applauded, turned to me as he finished the speech. I replied, "My friend, I come from the State of Ohio. Now, is it really true that up here in Michigan those who give lectures on prohibition first fortify themselves with whisky and tobacco?" He was, for the time, evidently taken back a little, but then replied, "Well, stranger, that is just about what it amounts to."

I felt obliged to him for having coupled tobacco and whisky so closely together. Is there not something significant about it? And, again, our gibbering, bleary-eyed neighbor who was too drunk to be decent, on the seat adjoining, furnished us another link. Obscenity and filthiness belong to whisky; and so it transpires that tobacco ultimately leads not only to filth in habit, but to filth in thought.

Would you like to know something about the way this little household is carried on? I presume friend Cook will excuse me if I tell a little about their daily home life. I know he will when he considers that I do it only that it may give suggestions and possible helps to other homes. The morning service is shared by all. Each one has a Bible as well as a hymn-book. By the way, I do think a morning hymn is a grand thing to commence the labors of the day. Well, the Bibles and Testaments at Prof. Cook's were German in one column and English in the column right beside it, verse to verse. All four members of the family read a verse first in English and then in German; and I was astonished to hear ten-year-old Katie give the German accent in her childish voice as easily, almost, as if it had been her mother-tongue. Although she is younger than her brother, her womanly wit grasps a good many things quicker than he does. This confirms me in my idea of woman's fitness for business. Well, why do you suppose the whole family are learning German? I will tell you. Prof. Cook has taught regularly in the college for something like twenty years, without respite or rest, except his vacations during the winter; and even during these winter vacations he works harder, a good deal of the time, at our agricultural colleges in Ohio, New York, Wisconsin, and other States. They are talking of having, in a year or two, a two-years' vacation, and they are going to travel in Germany and other countries of the Old World. The children are as enthusiastic about the vacation in Germany as are the father and mother, and this is why they are pitching into German with such energy. You must not think that this boy and girl are little men and women, for they are just as childlike, and just as full of childish pranks, as any other children, and they sometimes beg to be excused from their lessons and work. Mamma and papa both have to remonstrate and urge, occasionally, just as they do in all homes; but notwithstanding all this it was a rare treat to me to find children of their age so fully posted in re-

gard to general matters of life as were these two. A little picture on the sideboard shows the face of one that was in this household, whom God has called away; but the whole atmosphere of this home is a trust in God, and a reverence and respect for the great Creator of this vast universe, that has given me a lift upward as well as onward that I trust I shall not soon forget.

A great problem lies before us—How shall we manage to have the children of our homes pure in heart? How shall we contrive to have them grow up pure in heart? In the first place, my friend, do as Josh Billings recommended—walk in the path yourself in which you would have your children walk. When you are tempted to be selfish, when you are tempted to relate an impure joke, when you are tempted to do something in the dark that you would not do in broad daylight, consider, first, “If the little ones of my home were right before me, would I do this?” You may be surprised somewhat, my friends, but the above plan has been of great help to me indeed. I once labored about an hour with an intemperate man. He had always been a drinking man, and he declared his purpose of continuing so. When I had got as far as the door, thinking I should have to give up the task, I turned to him once more. “My friend, you say you have been drinking intoxicating liquor all your life, and you propose to go ahead so long as God lets you live—drinking when you please and all you please.”

He frankly declared I had stated just about the truth of it.

“Well,” said I, “friend B—, do you desire to have your boys grow up in just that way?”

He did not answer. I repeated it with more emphasis. When forced to reply, he said, with an evident softening in his tone, “No, Mr. Root, I do not want my boys to grow up to be drinking men.”

Now, then, whatsoever you would that your own boys should be and do, do just that yourself. Set a good example before them, not only when their eyes are upon you, but in the darkness of the night, when no man is near. Do that which you would do were those inquisitive little eyes present; and in the deep recesses of your own heart let no thought get much of a lodgingplace that you would be ashamed to have the little ones look upon. I know it is a hard task; but I know, my friends, it can be done, through the grace of Christ Jesus.

One more word about keeping our children from contamination and evil. We can not get good vegetable plants by greenhouse culture. They must be put outdoors, and gradually get accustomed to the winds and frosts. They must be hardened by exposure before they can be of service. If our children are going to be of use to the world, they must know the world. At one time the schools in Medina were so exceedingly bad that it became a question as to whether it were wise to send the small children. Even our boy Ernest learned to swear before we knew it. The boy he was most in the habit of playing with took the name of God in

vain almost constantly. What was to be done? This was even before I professed to be a Christian. Ernest's mother had to bear the load all alone. She went to her Bible for help; she took the boy into her room and there alone talked with him. She followed him with her prayers when he was absent, and she questioned him about his associates and pastimes and amusements, when he got home. She let him go for a stated period to play with the bad boy over at our neighbor's; but before going he promised her to come back in exactly one hour; and, furthermore, he promised to come home at once unless Edson would stop swearing. He came home repeatedly. Finally Edson called out to him from the street:

“Hello, Ernest! If you will come out and play, I won't swear a bit while you are around.”

For a time Edson would forget; but by and by he played whole hours, and did not swear. Edson is a better boy for having been Ernest's particular playmate, and I don't know but that Ernest is a better boy for having had Edson for a playmate. When he got older, worse things even than blasphemy were brought to his childish ears; but, may the Lord be praised, the close acquaintanceship between himself and his mother, brought about mainly from the fact that his mother had pulled him through these other things, kept him safe from contamination. He told his mother about things he had heard, and his mother fortified and strengthened him against these new evils. He talked with her frankly about things that mothers often feel as if they could not talk about to their grown-up boys.

Dear fathers and mothers, may I suggest a thought to you here? The growth of the vegetable world is a wonderful thing. The germination of seeds is, to every child, intensely attractive. The little downy chickens that come from their shells, in obedience to the instincts and care of the mother bird, are a never-ending wonder and attraction to the little ones of your household. Now, if you can talk with them about these things, and explain to them the wonders of God's creation, as seen in the sprouting of seeds and the bursting of egg-shells, can you not, when these same juveniles are a little older, tell them of the greater wonders that pertain to the matter of human life? God will guide you and give you wisdom and discretion in these matters, if you go to him prayerfully and go to him with your Bibles. Who but a father or mother is so well fitted to explain these things pertaining particularly to this matter of father and mother, and their relationship to the human family? Inasmuch as the Bible does not hesitate to speak of these things plainly, it seems to me that every parent has not only a right, but it is a sacred *duty* before him; and this duty should be taken up whenever the child is able to read God's sacred word understandingly. And, dear friends, is it not possible that this plain, frank way with your children would do much toward preventing them from getting hold of foul language and impure words? Where did those boys whom I overheard in the hotel

learn all this? Surely not from father nor mother.

While speaking about letting children play with neighbor's children, a friend made the remark that evil many times comes from letting the children make too long visits. Let them go for an hour, or half an hour, perhaps, and be sure that they are taught to be prompt and punctual. Be very careful about letting them go away to stay over night. The parents should know exactly when the children retire to rest, and, above all things, the company they are with at such times. Some poor woman may say, in despair, "How can I, with all my cares, keep such unremitting watch as all this demands?" Dear mother, what is the most important commission that God has ever placed upon you? Is there any duty or any task in life that comes any thing near being so important as this one of bringing your children up in such a way that they shall be pure in heart? Those that are pure in heart shall see God. To them is this promise given, and to none others.

REPORTS DISCOURAGING.

A LOSS OF 18 OUT OF 21 DURING WINTER; WHAT KILLED THEM.

IF you really long for some "reports discouraging," I can furnish you with at least one such. If I do not take the "first premium" I shall at least hope my chances for second are very fair in the line of poor success, or, if you please, "awful bad luck," during the past winter. And if you can "help us out of our trouble," as you intimate your ability to do, it will be some compensation for the "doleful story" of my last winter's experience.

I prepared for winter, as early as Nov. 1, 21 colonies, rather stronger than usual. I packed in dry leaves, and covered with carpet two or three thicknesses above, and with sufficient honey, as I thought, said good-by to them for the winter. I did not say farewell for ever, for I thought we should meet again when the "flowers that bloom in spring" should entice them and myself from our winter quarters. But we didn't. Eighteen out of that possible 21 have gone to gather nectar where "everlasting spring abides, and never-withering flowers." At least they have "gone dead," *awfully* dead, and will never again visit any flowers here. "How did it happen?" you say. Well, I wish you would tell me. That is just what I want to find out. If I can, and you thus help me out of my trouble, perhaps I may be able next winter to save more than one out of seven; that is, if I can hope to increase to so numerous an apiary from my remaining trio of brave survivors. Now don't put me in Blasted Hopes. I am not there at all. I am not even discouraged, for—well, haven't I three colonies left? and I dare say that is three times as many as some poor unfortunates can boast who last fall were beginning to calculate what investments they would make of the profits of this year's honey-crop.

I presume you are inquisitive enough to wish to know what manner of hive to attribute this loss to. Well, I use three kinds of hives—the Chaff Eclectic,

the American, and a nameless hive made by a neighbor by the name of Pierce, and I call it, hence, the Pierce hive. It holds six frames, and is very deep—18 inches by 10. My three surviving colonies were in these hives. I am credulous enough to think that the depth of these hives had something to do with the safety of these lucky little fellows—especially as in past winters my losses have been chiefly in shallow-frame hives—Simplicity, etc.

One other circumstance I ought to mention, and that is, that I had my bees on the north side of a board fence, and facing north. Did that have a necessarily fatal effect? I have wintered that way before. Do you ask why? Simply because I do not own the south side of that fence. If I did I would put them there.

Tell me all about the reasons for my "awful bad luck" the past winter, if you can. J. F. PATTON.

New York, May 4, 1887.

Friend P., while I should hardly think that putting bees on the north side of a fence would be fatal to them. I should call it a rather unfavorable location. While reading your letter I was wondering if there were not some starvation about it. You say you left them with sufficient honey, as you thought, but you don't tell us how much was left when you found them dead. I can not tell you where the failure came in, as you state it; but I do think, that if you put up your bees in chaff, packed as we describe in the A B C book, you can succeed in wintering as well as others do.

OUR OWN APIARY.

CONDUCTED BY ERNEST R. ROOT.

BEES IN NICE CONDITION.

OUR bees are in splendid condition, and I think I never saw more brood in the hives at this time of year than now, although the spring is a little late.

These young bees have come in at just the right time, for we notice that the old bees which withstood the hardships of winter so well are now becoming scarce. So far we have not fed, as we desire to let the bees clean out their combs entirely of all remnants of honey fed from last fall and summer. A little later, if apple-bloom should not furnish us honey enough we will feed.

It is over six weeks since we have had a case of foul brood; and if you could look into the condition of our colonies, and see the clean healthy brood, and the number of young bees, I believe the most skeptical of you would acknowledge that, so far as appearances are concerned, we have fully eradicated the disease.

So confident do we feel that we have cured foul brood, that we have decided to put the two loads of bees from friends Rice and Shook into our home apiary. We now have 240 fair colonies, with brood and young bees in all stages of development. I believe we never had a nicer lot of bees, or as nice-looking queens as now, and we certainly never had brood more healthy-looking. Unless some of our customers object, we will fill

orders for bees and queens from the home apiary. All those of you who may see fit to place with us your orders for bees and queens, we feel sure need not fear trouble from foul brood, as certainly the disease would have made itself manifest ere this had there been any trace of it. Those of our customers who would prefer not to have their orders for bees and queens filled from our own apiary, can have them filled from Neighbor H.'s apiaries by so stating at the time of ordering. I believe it is an axiom among those who have had to do with foul brood, that the disease can not be communicated from bees and queens when shipped in cages.

Remember, we are selling bees by the pound for just half what we sold them for last year. We did not bring the price down because we thought the bees were any less valuable, but because we thought our former price of \$2.00 a pound in the month of July was rather too high for those who were desirous of economizing. A few years ago, when we put the price of bees up, we had been sustaining heavy winter losses, and we felt that we could not therefore furnish bees then at a dollar a pound in July; but for the past four or five years we have wintered bees without any loss to speak of; and with 200 or more good colonies to begin with in the spring, we decided that we could easily return to our old prices—\$1.00 per pound for nice young Italians in July and after, and a corresponding increase during the cooler months of the year. For this month our price is \$1.50; next month, \$1.25 per lb.

APIARISTS' HATS.

We have just received a consignment of those nice light summer hats for apiarists, such as was illustrated on page 1001, last year, and described on page 30 of current volume. The covering of said hat is cloth of a light drab color. The brim is held out in position by a light steel hoop. The inside of the crown is so made that it is adjustable, and will fit any head. The lower side of the brim is covered with green cloth. When the hat is on the head, it feels so light and easy that the wearer scarcely knows that he has any covering at all over his pate; and the green color on the under side of the brim has a kindly effect upon the eyes. I have tried quite a number of hats in the apiary, and the one answering the description above is the one I very greatly prefer to all others. I know of no hat that is better adapted for holding the veil away from the face, and I think the apiarist who will give this hat a trial for one season will not wish to go back to the unsightly, uncomfortable, and often ill-shapen straw hat. We can furnish the apiarist's hat folded in a neat package for the small sum of 20 cts. each; 10 for \$1.80; postage, each, 2 cts. extra.

JERKING THE HANDS BACK AWAY FROM THE TOP OF THE FRAMES.

The other day, as I was passing through the apiary I noticed one of our new men jerking his hand nervously away from the top of the frames. I surmised that a bee had bumped against his fingers, with the apparent intention of inflicting a sting. When

I reached him I found that I was correct. I told him to try holding his hand perfectly motionless the next time a bee darted forth and bumped against his fingers. It might require some nerve force, but that if he would try holding his hand still and let the bee know that he was not afraid of it, there were ten chances to one that it would not sting him. He did as I told him, and afterward reported that it worked as I had said. I give this little fact, not for the benefit of the veterans, but for beginners and A B C scholars. You will save many a hard sting by holding your hand perfectly still when one or perhaps a dozen bees strike against your fingers. When you notice the tendency on the part of the bees to dart out that way you should give them plenty of smoke over the top of the frames; and as often as they try to scare you, give them a little more smoke.

CROSS HYBRIDS.

On the 11th of May we purchased four colonies of a farmer residing some two miles from our place. When the bees arrived I told the boys to take out the frames and place them in our Simplicity hives, as they had done with the forty other colonies purchased of friends Rice and Shook. Not suspecting any trouble, I went into the office and was seated composedly. In about half an hour, father came in and said, "You had better go out and see what the boys are doing. The bees are pretty cross. Find out whether there are any pieces of brood or honey broken and lying around." I went out to the apiary immediately. I made my way directly to the spot where the boys were taking the combs and placing them in the Simplicity hives. As I neared the place Mr. S. called out, "Better put on a veil before you come here." I needed no second caution. Taking a roundabout course I went to the house-apiary and procured a veil. On coming up I found that the bees were indeed, to put it mildly, "awful cross." There were perhaps 200 of the little scamps flying around the heads of all three of us, giving that angry hum such as is heard from all cross hybrids. I found there was nothing particularly wrong, only that the bees had not been handled before for a year or more; that being hauled a couple of miles and then stirred up they were determined to vent their spite right liberally. I told the boys that they had better desist for the present. On looking over toward my house which is in process of building (some 300 feet away) I noticed one of the masons striking wildly in the air as if mosquitoes or some other small insects were disturbing his peace of mind. I began to conclude that those vicious hybrids were not content with buzzing around our heads, but were so considerate as to call upon the masons. I immediately went over and inquired whether the bees were bothering them. They replied that they had killed a dozen or so "of them 'ere pesky little pioneers." Not content with bothering the masons they attacked one or two horses on the street, and even entered our saw-room amid the hum of machinery.

Right here, while I am about it, I believe

I have said I didn't care to use a veil. I rarely ever have occasion to resort to their use; but I must confess, that if I had such hybrids as these, and so strong in numbers, I should consider a veil one of the indispensables.

OUR HONEY APIARY.

We have definitely located our Honey Apiary some five miles south of Medina, and we expect to do some wonderful things in that apiary this summer. "Me and my wife" drove down there last week and completed arrangements.

GLEANINGS IN BEE CULTURE.

He that endureth to the end shall be saved.—MATT. 10:32.

T TINS—NUMBER SOLD UP TO DATE.

SINCE the first mention of T tins on page 156, current volume, the foreman of our tin-room informs us that we have so far made 36,000. This makes about 12,000 a month; and the demand, instead of decreasing, seems to be increasing.

MR. THOMAS HORN.

As quite a number of the friends have complained that they have not yet received their notes, as promised by Mr. Horn, on page 111, we wrote to him in regard to it, and here is his reply:

FRIEND ROOT,—I mailed, as promised, all notes excepting a few retained for further investigation, which I have since mailed; and now to the best of my knowledge all have their notes. If I have overlooked any, if they will kindly inform me I will mail them at once.

THOMAS HORN.

FIGHTING THE POTATO-BUGS.

TO-DAY, May 14, our Early Ohio potatoes that were started in the greenhouse are almost knee-high, and are doing splendidly, but the bugs are going for them to such an extent that one of the boys picked 34 off from one stalk. Our potatoes grow as stalks, remember, and not in hills. I have just written to friend Terry to know if I shall keep a boy picking the bugs off, or go back to the old-fashioned way of using Paris green.

TOTAL LOSS BY FIRE.

THE following letter from our friend Dr. J. P. H. Brown has just come to hand, which will explain itself:

I have just had the misfortune to-day of having my residence burned, including all my books, letters, and correspondence. I shall be much obliged to you if you will say that I will esteem it a favor if my customers will please send me at once their address, including a repetition of their orders. All orders will receive prompt attention. The loss of the house including its contents, is fully four thousand dollars, and no insurance. We could not save a thing out of the house, as the wind was blowing a gale.

J. P. H. BROWN.

Augusta, Ga., April 29, 1887.
Friend B., we extend to you our sympathy. We have no doubt, however, that you will be able to meet all your obligations.

PROF. BEAL'S NEW BOOK, "THE GRASSES OF NORTH AMERICA."

THIS is perhaps the most thorough and comprehensive work of the kind in the world. It is just from the press, and covers the whole ground most thoroughly, including the entire clover family as well as the grasses. Prof. Beal's clover-garden was one of the most interesting sights to me at the Agricultural College when there some years ago. He had a little plot of all the clovers known in the world; and near by were plants not exactly clovers, but nearly related to them, such as peas, vetches, etc. Among the subjects treated of in the book are Grasses for Cultivation, Grasses for Meadows, Care of Grass Lands, Making Hay, Grass for the Lawn, Garden, and Decoration; Enemies of Grasses and Clovers; the Fungi of Forage Plants, including corn-smut. Weeds in the Meadow is a department that interested me greatly. The price, \$2.50, may be thought by some a little high; but it is a most thorough piece of work by a most able man. There are 457 pages, and the book is fully illustrated, for the most part excellently. We can mail it on receipt of price given above. The author is professor of forestry and botany in the Michigan Agricultural College.

CAN BEES BE MADE TO HIBERNATE?

SINCE our article on page 343 was published, in regard to the secret possessed by the Indians, of keeping bees from fall to spring in a dormant state, several communications have been received—one from Mr. C. E. Jones, of Delaware, Ohio. Mr. Jones says that an old missionary assured him that he had buried bees in dry dirt, after causing them to fill themselves with honey, and kept them till spring. Friend Jones himself has experimented with bumble-bees in this way, and thinks that, because he succeeded with the latter, it might be done with honey-bees. Of course, this is a mistake. For years past, different individuals have told about bees that were brimstoned, and buried in the ground, but when dug out in the spring (by accident, of course) they came to life and were as good as ever. Now, while there may be truth in these oft-repeated assertions, I very much doubt it. When these statements are sifted it turns out that somebody else did it besides the narrator. If, however, there is a man who has buried bees in dry dirt, and kept them months, and afterward brought them to life, we shall be glad to know it. And when such an individual shall go to work and demonstrate it before good witnesses, we will then give up that bees can be made to hibernate. Now, don't feel hurt, any of you, dear friends. We are not doubting anybody's word. We are only asking for accurate facts in the matter.

HUTCHINSON'S NEW BOOK.

THERE have been some criticisms sent in, in regard to this work. It is true, friend H., in the book, invites the freest criticisms; but some of them are not in as courteous a spirit as they ought to be, to find place in a periodical. On page 233 of the *American Bee Journal*, Prof. Cook quotes me as follows:

"I read Mr. Hutchinson's new book on comb honey, as I came here. It is so good that I have only one criticism—it is too short."

It is true, I did say that, or something very much like it, but I also added, or, at least, intended to add, that I should give it the same criticism I did Dr. C. C. Miller's new book—the absence of engravings to make matters plain. A busy man like myself could

A LAWN MOWER

FOR ONLY \$5.00.

Isn't it true, that a neatly kept lawn is evidence of an intelligent and progressive spirit possessed by the owner? A lazy and shiftless man seldom has any lawn at all. Many whose occupation keeps them indoors a great part of the day, derive health and enjoyment in taking care of a lawn, even though it be just a little one. And what makes life pleasanter than to see pleasant homes as we happen to pass along our country roads or village streets? Where you see a handsome lawn outside, you will almost always find the magazines and progressive journals of the day inside. One impediment in the way of these handsome lawns is the expense of a lawn-mower; and as we have spent some time in looking the matter up, and trying the different kinds, especially those adapted to mowing around bee-hives, I herewith give the result of it.

The one pictured seems to please us best of all for working in the apiary; and another thing that pleases me is that it costs for the 10 inch, only \$5.00; 12 inch, the standard size, \$5.50, and the 14 inch, \$6.00. The 10-inch one runs a little easier, of course, and it may therefore be preferable for a lady or for a child. Its simplicity is an advantage in the apiary, for it will run up close to the entrances, and it will cut weeds and grass of a considerable height without difficulty. We can furnish them promptly at the prices named. As the machine weighs but 50 lbs., it will probably go cheaper by freight.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough to these queens to pay for buying them up and keeping them in stock; and yet it is oftentimes quite an accommodation to those who can not afford higher-priced ones.

FOR SALE.—Five mismated Italian queens to spare, at 50 cts. each, reared from pure Italian mothers. Write soon if you want them.

CHAS. MCCLAVE, New London, O.

FOR SALE.—About 10 hybrid queens, at 40c. each, by return mail.

G. D. BLACK,
Brandon, Buchanan Co., Ia.

I have 3 mismated Italian queens, of this year's rearing, for sale at 35c. each, or the 3 for \$1.00.
A. P. STAIR, Whitney, St. Clair Co., Ala.

I have about 12 black queens to spare—one and two years old; prolific layers; 25 cts. each; or 5 to one address, \$1.00. LUTHER PURDY,
Killbuck, Holmes Co., O.

SEE HERE!—60 black and hybrid queens for sale; are good laying queens, nearly all young, and are sold to make room for Italians. Ready now. Satisfaction and safe arrival guaranteed. Return all dead queens in same cage; all clipped. Price 30 and 45 cts. L. T. AYERS,
Box 657, Kankakee, Kankakee Co., Ill.

I have five black and 10 hybrid queens that I will sell for 20 and 30 cts. respectively, or the whole lot for \$3.00, ready by May 20. W. H. LAWS,
Lavaca, Sebastian Co., Ark.

Hybrid queens, reared from select tested Italian mother, for sale at 50 cts. each. Safe arrival and satisfaction guaranteed. GEO. W. BECKHAM,
8-9 10d Pleasant Hill, Lancaster Co., S. C.

Black and hybrid queens at your own price. First come, first served. D. M. KENZIE,

Two-frame nuclei, \$3.00; 3-frame, \$3.50. If larger nuclei are wanted, add 50 cts. for each additional frame. Full colony in A. I. Root's Simp. hive, \$6.00, each to contain a tested queen and plenty of bees and brood, all on wired L. frames drawn from fdn. To be shipped in May; safe arrival guaranteed. I shall do by all as I would be done by. Address 7-10db. N. A. KNAPP, Rochester, Lorain Co., O.

W. Z. HUTCHINSON,

ROGERSVILLE, GENESEE CO., MICH.,

HAS the permission of the writer to publish the following:

Forest City, Iowa, March 28, 1887.

W. Z. Hutchinson, Rogersville, Mich.—Dear Sir and Friend:—I am in receipt of your pamphlet—"The Production of Comb Honey." It is the nearest little thing I have seen lately. As a work of art it is as near perfection as printers in 'country' offices usually attain to. I venture the opinion that that cover was the work of a bee-keeper, or at least originated in his (your) creative brain. Nobody but a bee-keeper would have thought of such a unique and appropriate covering. The subject is treated in a very readable and creditable manner. I have been practicing substantially the same method, except the non-use of foundation. I shall try that this season. Respectfully yours, EUGENE SECOR.

Reader, if you wish to enjoy the same pleasure as did Mr. Secor, send 25 cts., and a copy of the book will be sent postpaid. 10tfdb.

LOOK HERE!

Dollar queens ready to ship; 500 lbs. of bees; 1000 lbs. comb foundation, and a large stock of supplies. Will be sold at rock-bottom prices. Send for our price list of 1887, now out.

POTATO BOXES

(TERRY'S).

These are made of basswood, bound with galvanized iron. The galvanized iron gives strength, and the basswood strength and lightness. These hold exactly a bushel when level full, and may be piled one on top of another. Although they are made especially for potatoes, they can be used for fruit, vegetables, picking up stones on the farm, and a thousand other purposes. When piled one above the other, they protect the contents from the sun and rain; and from their shape a great many more bushels can be set into a wagon than where baskets are used. They are also much more substantial than baskets.

Price 25 c each; 10, \$2.25; 100, \$20.00. In the flat, including nails and galvanized iron, \$1.75 for 10; 100, \$16.50; 1000, \$150.

A. I. ROOT, Medina, O.

There is Some Fun

And much sense in our beautiful chromo card described on pages 83 and 112. Sense to tell people in a neat way what you have to sell; and fun to take in the money. Look it up, or address

PASTEBOARD BOXES

FOR ONE-POUND SECTIONS OF

COMB HONEY.

This box has a bit of "red tape" attached to it to carry it by. It makes a safe package for a single section of honey for the consumer to carry, or it can be packed in a trunk, if he wants. It can be opened in an instant. The price of the box is 2 cts. each, set up; in the flat, 15 cts. for

10; package of 25, 30 cts.; \$1.00 per 100; or \$9.00 per 1000; 10,000, \$80. If wanted by mail, add \$1.00 per hundred for postage. Colored lithograph labels for putting on the sides, two kinds, one for each side, \$3.00 per 1000. A package of 25, labeled on both sides, as above, 50 cts. By mail, 30 cts. more. They can be sold, labeled on one side or both sides, of course. We have only one size in stock, for Simplicity sections. Sample by mail, with a label on each side, 5 cts. If you want them shipped in the flat, labels already pasted on, the price will be ten cents per hundred for putting them on.

Your name and address, and the kind of honey, may be printed on these labels, the same as other labels. The charge for so doing will be 30 cts. per 100; 250, 50 cts.; 500, 75 cts.; 1000, \$1.00.

A. I. ROOT, Medina, Ohio.

JOB LOT OF POULTRY-NETTING.

Small Pieces at same Rate as full Rolls—1 ct. per Square Foot.

Two or more pieces, 5 per cent off; ten or more, 10 per cent discount.

You will notice in this lot some with heavier wire than No. 19, and some with smaller mesh than two-inch. Both of these are worth more at regular prices than two-inch No. 19; but as it is a job lot we put it all in at the same price.

By dividing the number of square feet in this column by the width in the first column, you can ascertain the length of each piece. These figures give the number of square feet in each piece.

Inches wide.	Inch mesh.	No. of Wire.
6	2	18 10.
12	2	19 91, 85, 50, 41, 40, 25, 25, 10.
12	2	18 70, 15, 13, 13, 1½ mesh, No. 17 wire, 24.
18	2	19 150, 150.
24	1½	20 120, 120.
24	1½	19 220, 64, 28, No. 18, 200, 1½ inch mesh, 62.
24	2	19 300, 170, 140, 130, 100, 100, 88, 82, 64, 64, 56, 50, 50, 40, 32.
24	2	18 225, 224, 58, 58, 56.
30	1½	19 41, 32, No. 18 wire, 90, 40, 30.
30	1½	19 75, 55, 17.
30	2	19 250, 237, 167, 125, 125, 122, 45, 40.
30	2	18 150.
36	1½	19 144, 114, 75 No. 20 wire, 348, 312.
36	1½	18 108, 39.
36	1½	19 27 No. 18 wire.
36	2	19 345, 330, 270, 255, 246, 240, 204, 204, 198, 195, 132, 126, 75, 75, 60, 57, 33.
36	2	18 360, 114, 72, 51.
42	2	19 350 No. 18 wire, 203 No. 18, 1½ mesh, 180.
48	1½	20 40.
48	2	19 264, 200, 68.
48	2	18 172, 60.
54	2	19 450 No. 18 wire, 224.
60	2	19 595, 490, 445, 385, 335, 330, 325, 285, 280, 240, 225, 220, 210, 180, 165, 160, 140, 130, 80, 50.
60	2	18 470, 335, 320 No. 17 wire, 195.
72	1½	19 438, 312, No. 18 wire, 228.
72	2	19 750, 720, 690, 672, 636, 618, 558, 510, 438, 438, 420, 270, 252, 252, 222, 192, 168, 168, 162, 162, 156, 146, 156, 126, 130, 66, 48.

We know of nothing nicer or better for a trellis for creeping vines than the above netting. The 12 to 24 inch is just the thing to train up green peas, fastening the netting to stakes by means of staples. If the stakes are set in substantially, one each 12 or 15 feet will answer. When the peas are stripped off the stakes, netting and all can be rolled up and laid away until another season.

KIND WORDS FROM OUR CUSTOMERS.

FOUNDATION VERY NICE.

The foundation you sent is very nice—or, at least, the one box we looked into is very fine — the nicest we ever received from you or from any one else.

RANDALL & SEARES.

Girard, Erie Co., Pa., Apr. 22, 1887.

THE SMOKER JUST THE THING.

The smoker I ordered March 1st arrived April 2d. It is just the thing I wanted. I tried it this week. My wife says it makes too much smoke. Accept my thanks for your promptness.

M. A. JOINER.

Waterboro, Ga., Apr. 9, 1887.

THE SMITH PUMP PUT TO A SEVERE TEST.

The Smith force-pump has arrived, and has been put to the most severe test. I am perfectly delighted with the result, as it is a much better article than I had any idea could be obtained for so small a sum.

W. B. DILLON, Sec. Coraopolis School-board,
May 11, 1887. Coraopolis, Pa.

THE WHEELBARROW A BEAUTY.

The bill of goods you shipped me came to hand in due time and in good order. The wheelbarrow is a beauty—the nicest that ever came to Southwestern Wisconsin. "Fables and Allegories" is a "daisy." All the goods are No. 1.

G. L. HALL.

Waldwick, Iowa Co., Wis., Apr. 27, 1887.

I commenced getting GLEANINGS something over a year ago. When I saw your Tobacco Column, and how much you were interesting yourself in it, I determined to quit smoking for one year. I had quit chewing something over ten years ago. The year was up some time ago, and I have saved more than the price of GLEANINGS on that.

W. S. CONFER.

Hemlock, Pa., Apr. 11, 1887.

A PLEASED CUSTOMER.

The bees I received from you, shipped on the 19th, arrived on the 26th in magnificent style, and are doing finely so far. Express charges were \$2.70. The extreme care you seem to take in having your bees reach your customers safely is very commendable, and I must express my delight in receiving mine so promptly and in such excellent shape, as these are the first in the country.

J. N. COE.

Lincoln, New Mex., Apr. 29, 1887.

A KIND WORD FROM FRIEND STALHAMMER, AWAY OVER IN SWEDEN.

Your kindness and generosity toward me, in offering me GLEANINGS by way of exchange, with my very humble *Svensk Btidsning* (Swedish Bee Journal), far exceed any thing I could have expected, but when getting so liberal a proposal I can not but gratefully accept it.

I suppose I shall never be able to pay a visit to

you, a man not only a pre-eminent bee-keeper, but also well conversant on any thing pertaining to agriculture, gardening, stock and poultry raising, etc., and trying to spread broadcast all over the world and amongst your fellow-creatures the results of your experience, ingenuity, and faith, thus giving us plenty of material and needed help, only because you are and always will be a true Christian, above all. I hope you will kindly excuse my boldness in sending you my photo. Your good and kind heart will also be sure to excuse me in offering you to kindly accept the two following treatises of mine: "Theoretical and Practical Manual of Bee-Keeping," and, "The New Way of Cultivating Potatoes"—my own way as well as that of Mr. Terry—the one copy of the Manual to be forwarded to Mr. T., that gentleman having already the treatise on potato culture. I am fully convinced those books have only a very small value to you, if any; but I am sending them as a testimony and token of my esteem and gratitude to both of you. I suppose it will interest Mr. Terry very much to know that his book is reproduced in my book, and now is translated into German and spread over all that country. I beg you to kindly read the preamble of the treatise on potato culture. There you will see the testimony of the great esteem in which I hold you.

H. J. STALHAMMER.

Gotheborg, Sweden, March 11, 1887.

[Friend S., it was quite a pleasure to look your books over, even though we could not read them; and it is gratifying to us to know that friend Terry's teachings have gone outside of our own language.]

BEES by the POUND At \$1.25.

Safe arrival and prompt delivery. No queens nor circulars. 275 colonies to draw from.

Address T. P. ANDREWS,
11d Farina, Fayette Co., Illinois.

I WILL SELL combs, drawn from wired fdn., in metal-cornered frames, well covered with bees, over two-thirds filled with hybrid sealed brood, for 75c each; 10 or more frames, 20 per cent discount. Also a few tested Italian queens at \$1.50 each, one year old.

11d H. P. LANGDON, East Constable, N. Y.

DADANT'S FOUNDATION

is asserted by hundreds of practical and disinterested bee-keepers to be the cleanest, brightest, quickest accepted by bees, least apt to sag, most regular in color, evenest, and neatest, of any that is made.

It is kept for sale by Messrs. T. G. Newman & Son, Chicago, Ill.; C. F. Muth, Cincinnati, O.; Jas. Heddon, Dowagiac, Mich.; Dougherty & Wiley, Indianapolis, Ind.; B. J. Vol. XV.

JUNE 1, 1887.

No. 11.

TERMS: \$1.00 PER ANNUM, IN ADVANCE; 2 Copies for \$1.50; 3 for \$2.75; 5 for \$4.00; 10 or more, 75 cts. each. Single number, 5 cts. Additions to clubs may be made at club rates. Above are all to be sent to ONE POSTOFFICE.

Established in 1873.

PUBLISHED SEMI-MONTHLY BY

A. I. ROOT, MEDINA, OHIO.

Clubs to different postoffices, NOT LESS than 90 cts. each. Sent postpaid, in the U. S. and Canada. To all other countries of the Universal Postal Union, 18 cts. per year extra. To all countries not of the U. P. U., 42 cts. per year extra.

FRIEND POPPLETON'S REVIEW.

THE "EXPLANATION AND DEFENSE."

BEFORE me lies a copy of the *Bee-Keeper's Guide* for April, 1886. According to the tables published in this number, its editor had been wintering bees in the cellar only three winters; and the saving in stores by cellar wintering was, upon an average, two pounds and nearly one ounce per colony. I presume some of my readers are ready to exclaim, "I guess you were a little wild! Two pounds and one ounce of honey will not pay four times over the expense of cellar wintering." Not so fast, my friends. Have you any idea what it costs to winter bees in a cellar? You, Mr. Editor, put it at 25 cents per colony, when you were reporting the Michigan State Convention, held in Lansing two or three years ago. Well, I'll tell you, my friends, the conclusion I arrived at, and I reached it in neither a wild nor a careless manner, but by careful inquiry, by correspondence and otherwise, and it is this: Bees can be wintered in a cellar at a cost of *three cents per colony*! Counting a man's time at one shilling per hour, they can be carried in and out of a cellar for 2 cents per colony, and the interest upon a cellar or repository will vary from half a cent per colony to one and a half cents. My cellar under my house will hold 100 colonies, and it cost not far from \$10.00. The soil is hard clay, the walls are given a slant, and no stone walls are needed. Mr. R. L. Taylor has a new cellar under his honey-house. The walls are stoned up. The cellar cost \$50.00, and will hold 250 colonies. Mr. J. H. Robertson has an outdoor cellar made of boards, and the walls are filled with sawdust. I think it cost him about \$40.00, and I at one time saw 250 colonies inside of it.

After having made the assertion in regard to the

saving of stores by cellar wintering, I then said: "But, of far greater importance, it is only by the cellar method that the wintering of bees can ever be reduced to a *perfect system*."

With all the care that I took in writing my book, to have it so worded that readers would be compelled to understand it, I now see that the above is liable to be misconstrued. If I understand Mr. Poppleton he has, I think, misunderstood me upon this point. By a "perfect system" I mean one that secures *uniform* results. Prof. Cook, in his article in the May 1st issue, covers this point so completely, and in so few words, that I will quote them. He says: "Now, why I prefer a cellar is this: If the cellar is right, we are always safe, providing we look out for food. With chaff hives, we are not safe; at least, it so seems to me, even in the latitude of Central Ohio. Occasionally a long, severe, uninterrupted winter comes, and the bees are swept away, when those in the cellar are as safe as ever."

Friend Poppleton says: "I do not think that yourself, or any one else who practices your general system of management, will, as a rule, be successful in outdoor wintering." No reasons are given for this belief (I wish there had been), and I have puzzled over it quite a little without being able to so much as arrive at a *guess*. I have always worked a few colonies upon the old plan (the same as almost everybody works them), and have wintered part of them upon the summer stands and part in the cellar, and also wintered, upon their summer stands, part of the colonies worked in the new way, and I have failed to see that the latter wintered one whit behind the others, whether in the cellar or out of doors; while those worked upon the "Hutchinson plan" have always yielded a greater profit. Mr. Donane lives $2\frac{1}{4}$ miles from here. He does not believe in "contraction" nor "starters

only," nor does he practice "sugar feeding" in the fall. He came over a year ago and bought my empty combs. He hives his swarms on ten L. combs, and winters his bees in chaff hives. His percentage of loss the last winter is much greater than mine, with many weak colonies, while almost every colony of mine is "booming." I fail to see why the cellar method of wintering is any more essential to success with my methods of management than with any other method; but, even if it were, I should still adhere to it because it is more profitable, and, by cellar wintering, stores can be profitably saved, and more uniform results secured.

In the next paragraph Mr. P. brings up a point that I had overlooked; viz., that spring protection will enable us to successfully practice the spreading of brood; and Mr. Doolittle, in the last number, gives an excellent article on—well, I should call it *contracting* the brood, but I still feel that I have no desire to change the following, taken from page 14 of "The Production of Comb Honey."

"Judging from my own experience, and the reported experience of others, it is my opinion that an experienced apiarist, *having more time than colonies*, may sometimes, by exercising great caution, practice to advantage stimulative feeding, or spreading of the brood, in the spring; but in a very great majority of cases, if not in all cases, I think it much better to simply see that bees have an abundance of sealed stores, then pack them up warmly and let them alone."

I wish to call attention to the words that I have italicized. If an apiarist has more time than colonies, and can get no more colonies, it will be profitable for him to so manipulate the ones he possesses as to receive the greatest amount of honey per colony; but when the question is viewed in a broader light, viz., that of securing the greatest amount of honey with the least expenditure of capital and labor; when we attempt to combine capital, labor, and the honey-producing area, in the *most profitable* manner, I believe that the spreading of brood must step down and out.

In regard to separators, I have so many times given my views to the public that I will not repeat them. When my honey takes first premiums at fairs, and is pronounced by dealers as the "finest," and they "didn't know it *was* raised without separators" until I so informed them, why should I trouble with separators? I have explained, in my book, their advantages and disadvantages, the conditions under which they are needed, and the methods necessary to their abandonment.

I have never seen a two-piece section; but if, as friend P. says, "it has the good but none of the bad points" of other sections, I am for it.

Friend P. takes a "square and decided issue" with me in regard to using empty combs in the brood-nest when hiving swarms, if we are raising *extracted* honey. Candidly, I thought the taking of swarms, either comb or extracted, from the brood-apartment was one of the things of the past. It is much more convenient to have the brood in one apartment and the honey in the other. If Mr. P. would use no larger brood-chamber than one that will contain sufficient stores for winter, and *desires* to winter his bees upon *natural* stores, I then see no objection to using empty combs in the brood-nest when hiving swarms, in raising *extracted* honey; i. e., if the bees will store just as

much honey in the aggregate; but I prefer to have autumn find the brood-nests nearly free from honey, because I can then fill them with sugar syrup at a *profit*, and feel certain that the bees have the best of food for winter. I will admit, that, in raising extracted honey, the profits arising from wintering bees upon sugar are very slight—not sufficient, perhaps, to be of any great account; but the safety attending the use of sugar for winter stores is very great; and, in raising *comb* honey, the profits are considerable.

In regard to Italians vs. blacks, I have noticed this: When the honey resources are poor, and much work must be done to get any honey, the Italians are superior, and will store the most honey; but in the "short, sharp flows of honey," which is the way we get most of our surplus here at the North, the simon-pure blacks have no superiors. It is surplus honey that we are after, and I have always secured just as much surplus from the blacks as from the Italians, and, as explained in my book, some of the manipulations are much more easily performed and the honey has a finer appearance.

The references to the pages of the *A. B. J.* should read "for 1884," instead of 1886.

Mr. P. has my sincere thanks for the fair and kindly manner in which he has criticised.

And now, friend Root, a few words in regard to your editorial remarks on page 408.

I do not think there is an idea in the book that could be made clearer by using an engraving. When reading it, was there any thing you failed to understand, that a cut would have made plain? If there is any obscurity that pictures will clear away, I hope the friends will point it out, and engravings shall be forthcoming in the first re-issue; but if pictures are not needed, why use them?

And now about the price being too high. I hope I may be pardoned for the apparent egotism with which I explain its cost. The book contains 45 pages of reading-matter, they being about 3x4 inches in size, aside from the margin. To write these pages I spent one whole month, writing scarcely two pages a day. Before writing any thing I tried to be certain that my facts *were* facts, in *fact*; then I set to work to give them in the fewest words possible. I wrote and re-wrote, and re-modeled sentences and paragraphs over and over again, until I felt that there was no redundancy, no froth, and that my readers *must* understand me; and having worked in this manner, I presume you well know, friend Root, how pleasant it is to have Dr. A. B. Mason say: "You just more than boiled it down, didn't you?" and Mr. G. W. Alves say, "The clearness with which the author states his ideas, together with his enthusiasm, raises his performance at times to some degree of brilliancy;" and Prof. Cook says, "This book shows him at his best," etc. I could have left the book at twice its size with one-half the labor. To condense is *work*. I agree with Mr. R. L. Taylor, that the value of a book or paper does not depend upon the number of words it contains, but rather upon the information; and if you, friend Root, would be willing to pay *double* price to have a book well illustrated, as a matter of saving in time, why not, for the same reason, pay at least an equal price for one that is "boiled down"? How many times have I laid down a bee-paper with the thought, "All the information that paper contains might have been

printed upon *one* page, and I would give more for the paper if the information were all on one page, and that that were all there was to it, as I should then have been spared wading through the froth." Have you never felt this way? Am I not right?

Well, when it came to publishing, the only first-class publishing house near here was at Flint, and that one was overburdened with work, and could work in a "form" only occasionally, and I had to go to Flint, and go to Flint, for another *month*, until it almost seemed as though I lived there. Then the getting-up of that cover, which has received so many compliments, was an experiment, or, rather, the result of a good many experiments; but then I put my *whole heart* into the work, spared neither time nor expense, used new type and the best of paper, and was determined that the book should be a little typographical *gem*; and how I did enjoy the work! but when it was finished, and I had figured up the cost, I found that I could not sell the book at less than 25 cts. and have a fair profit left. But I will say this much: If any purchaser is dissatisfied, and thinks the book is not worth the money, he may return it, unsoiled, and I will cheerfully refund the money.

I am more than willing to give friend Doolittle, or *any one*, all the credit that belongs to him; and if having given him credit in "two places" is not sufficient, I will continue to do so until everybody is satisfied.

W. Z. HUTCHINSON.

Rogersville, Genesee Co., Mich., May 20, 1887.

Friend H., if you think there is nothing in your book that can be made clearer by the use of engravings, then you and I will have to agree to disagree. On page 12 you speak of one section of Mr. Heddon's hive. I would by all means show what said section looks like; and then under the picture I would name it, "One Section of Mr. Heddon's Hive." I like pictures, and I always want a title to them—something to tell what the picture is intended to represent or explain. It always vexes me when I am compelled to read a couple of pages to tell what the pictures in any book are intended for. On the next page you speak of spring protection, and mention a rim 2 x 3 feet in size by 18 inches deep, made of cheap thin lumber. Well, it requires a mental effort on my part to build up in imagination something 2 x 3 feet in size and 18 inches deep. In the first place, I have to study over the matter somewhat to know whether you mean a box of the above dimensions, without top or bottom, or whether it is something else. You say, again, its front edges should rest on the end of a little bridge. I would have a picture of said bridge. A few lines further you speak of a shade-board. Show us a picture of the shade-board also. A while ago Mr. Heddon and myself wrote a column or more in regard to a misunderstanding about the flat cover of his hives. When I came to see a picture of the cover, however, it was as plain as could be. He had one thing in mind, and I another. If I am correct, some of the rest of the brethren dipped into our controversy too, all for the want of a picture. On page 14, you say, by tacking a strip across the two boards used for sides of the rim, they may be united and used for a shade-board. I should say, by all

means give a picture of said shade-board, put together as you describe. I can not even conjecture now what it would look like.

It is not worth while for me to go through the whole book in just that way; but I think I should want at least a cut for every page. These cuts cost money, of course, and it requires the personal supervision of the author of the book to get the engraver to understand exactly what the writer has in mind. But, suppose it does—what of that? And now to the other point. You say your time on the book amounted to so much that you could not afford to sell it for less than 25 cents. I know a great many people differ with me right here. But I presume no one will object if I again tell the way I feel about such things. In deciding what to sell a book for, I would not pay any attention to what it cost. I would put it like this: What will people be willing to pay for the book, comparing it with other similar books? Last summer a man sold me some pears. I tried to pour them into our own bushel boxes; but his bushels were so large, I couldn't get them in. I asked him if he was not giving too many pears for a bushel. He said he always liked to give good measure in every thing. There may be extremes in this, but I think it is a pretty good plan to go on.

There are three things we sell that people are always pleased with. In fact, this has been so invariably the rule in years back, that we send any one of these three things to anybody, without pay. The reason is, because we give so much for the money, that even a dishonest man feels he has got a bargain, and remits with a "thank you." The three things are, the A B C book, the cold-blast smoker, and GLEANINGS. Practically speaking, nobody ever has to be dunned to get him to pay up for these three. Where you say you will return the money to anybody who is dissatisfied, we come practically on to the same ground; for after a man has read the book through, you give him his money back, providing he simply pays postage. Now, I do not mean by the above that one is to continue selling a book he has put out, at a price that will not pay cost. I mean simply this: Give good measure compared with what the world usually gives in a book, and the large sales that will result from so doing will eventually pay you a better profit than the other way with smaller sales. The book is surely valuable. It is boiled down in the way you state; but if, in addition to this, you could have made the pages attractive with nice pictures, right in line with the valuable suggestions on every page, the book would have started out with a great boom, and this boom could be kept up by additions in the way of an appendix or otherwise, as fast as improvements come up.

I have taken some space for these suggestions, because I know they will be valuable to many of our book-makers. I have published books that have been quite a success, and I have also published some that have never realized a tenth of the money put out upon them. I was thinking a day or two ago, that if I ever felt called upon to write

another book it should be good measure, full of pictures, and I would lay my plans for a new edition, with additions just as fast as the book began to get the least bit stale or out of date.

OUR P. BENSON LETTER.

HIVIN JENNY'S SWARM.

THE summer Jo Stull bilt his 2 story hen house, 1 hot day Jenny Hutchisen see a swarm of bees a cummin lickity brindle, rite strate for thair house. It so happend that day that she was all alone and not a sole at home but her. Jenny's 1 a them girls whitch aint afeerd a nothin if she doant git flustered, and the 1st thot whitch cum into her hed, as she shet her teeth 2gether, was "Them air bees is mine." The bees was a slow-in up sum, and a kinda sailin roun & roun like, and Jenny diddent no much about bees but she heerd Carry Davis say that if you made a big noise so the bees cooddent hear the king, thade settel. So she just put both hands onto her waist, settled herself back a little, shut her ize $\frac{1}{2}$ open, opened her mouth to its fool cumpass, and let out sitch a yell yuda thot it was 25 locomotives & a wild Sue injun. That started out the Wilsons whitch jined farms with the Hutchasens. That was before Jack was married, and he was a running the farm that yeer on account of his father had fell and unjointed his thie bone. So when Jack heer Jenny a screechin and a screemin like the injuns was a scalpin of her, he made for his gun, thinkin they must be burglars to Hutchasens. Mary cum a tarin acrost the paster with a tin pale & a tirky egg into it, whitch she hed bin huntin tirky nests. Sid see Jack git his gun, so she called the dogs & followed, and Em she got the ax & cum pirty neer outrunnin them all. The 4 got there pirty much together, Mary's pale pirty well painted over the inside with the yallow of the tirky

minnit onto the hoopin & hollerin but jest jirked her hed towards where the bees was. Then thay noad what was the matter. Mary diddent waist enny time a considerin, but turned her tin pale upsdown and took a stone & went to poundin for deer life, the tirky egg a streamin down her dress. Em sez to Jenny, sez she "Shut yure big mouth and get sum pans and things. Thattle bring em down quick-ern shootin." "Will it?" sez Jenny, and then she tore into the house like mad and grabbed up the tin pale, the tongs, the dish pan, and a pan of sower milk a standin onto the table, whitch she deliberately upset the milk onto the middle of the floor, whitch she mite jist as well throad it out door, but then Jenny was flustered.

P. BENSON, A. B. S.

(To be konklooded.)

T. P. ANDREWS' APIARY.

MORE ABOUT IT.

IT is seventeen years since I became interested in bee culture, through the publications of H. A. King, whose hive, the American, I adopted and used for a few years. When I had increased up to about 80 colonies I transferred all my combs into the standard L. frame, and have used it since, exclusively. My main honey-crop has been gathered from tickseed (coreopsis), though usually called Spanish needle. I have never had any surplus from clover or basswood here, the absence of which has caused our annual honey-crop to average only moderate, as compared with more favored localities. Our bees have shown but little disposition to swarm, even when run for comb honey.

During the honey-yield this fall I had my bees, 300 colonies, all at home. I had 130 hives out about four miles; but about the middle of August, just before the coreopsis bloomed, the drought had become much more severe at my out apiary than at home, where we had had some local showers. I accordingly moved the bees home; notwithstanding, there were 300 or 400 more colonies owned within about 2 miles of my apiary. With 600 or 700 colonies in this locality I hoped to be able to throw some light on the question of overstocking, but I am not sure that I have reached any definite results. My honey-crop, mostly extracted, does not exceed 20 lbs. to the colony, fall count. That looks like overstocking. But, on the other hand, at some points a few miles away, bees have done no better than here; while at other places near the timber, where they had a run of honey-dew during June and July, bees have secured a larger crop.

In regard to the picture which appeared in GLEANINGS, page 14, perhaps I should explain that the apiary is arranged in squares of 16 hives each, with broad alleys running each way. The alleys run east and west. The view was taken from the south, and does not show very well in the picture. The smaller building on the left is my honey-house, where the extracting is done, and the surplus combs are stored when removed from the hives. The larger building is the shop where I manufacture and store my hives. The absence of large trees is due to the fact that, when I bought this 10-acre field, adjoining town, three years ago, there was not a tree on it. I have put up the buildings, but have to wait for the trees to grow.

Farina, Ill.

T. P. ANDREWS.

A WHOOPIN AND A HOLLERIN.

egg and they found Jenny a hootin away as loud as ever, standin right into the middle of the yard, her ize kinda sot like. "Whair is he?" sez Jack. Sez Mary "Whair's the fire?" sez she. Jenny wuzzent a goin to take no chances, and if noise was a goin to make them bees settel she woodent risk stoppin. Besides she was encurridged by seein sum of the bees begin to lite onto a jim. So she never let up a

RED CLOVER COMING UP WHERE ALSIKE HAS BEEN SOWN.

FRIEND MUTH SUBMITS TO US SOME CORRESPONDENCE ON THE SUBJECT.

FRIEND ROOT:—It happens once in a while in business, that an unpleasant feature turns up, even between two well-meaning men. A hasty conclusion, to which all of us are subject, is often the sole reason for an ill feeling and an unpleasant controversy. The object of this letter is to enlighten some of our friends on the subject of alsike-clover seed. Wherever I am wrong, I will stand corrected.

A few years ago you sold to our friend Demaree some alsike-clover seed, which, according to his statement, turned out to be red clover. I believe that every word friend D. said in the matter was the whole truth and nothing but the truth, to the best of his judgment. You claimed that the seed sent was alsike. I can understand that your clerks may have made a mistake, for mistakes are made by the best of us, and why not by our clerks? But I can not see why a farmer, being used to sowing red-clover seed, would sow it for alsike, or *vice versa*, without knowing the difference, as there is such a great difference in the looks and the size of the seed.

Again, I can not comprehend why that farmer should not remember, the following season, whether the seed in question had the appearance of red-clover seed, or whether it had not. Yourself and friend Demaree will find my article interesting, I believe, as I have just now a case exactly like yours, with the only difference that I can prove *my* side of the case.

In February, 1885, we sold to O. A. Cory, Frankfort, O., 1½ bushels of alsike-clover seed. My son put up the seed, and remembers exactly of putting it up for friend Cory, because it was the rest of the alsike seed we had purchased in the spring of 1884. We had new seed in already, but closed out to our friend Cory the tail end of the old seed. This fact serves us now as the best reminder that we shipped, to O. A. Cory, seed which we had bought and sold for alsike, which looked like alsike seed, and which we would hereafter buy again for alsike seed.

June 2, 1886, Mr. Cory wrote me that the seed I had sent him in the spring of 1885 had proved to be red-clover seed, that he had sown the seed himself on the field of a neighbor who had now a large field thickly set with red clover, but that he (Cory) was minus the value of his money sent me, and that I should refund part of the money.

Now, I will give you a copy of my letter, and his reply:

Friend Cory:—Your favor is at hand, and contents noted. To-day's mail brings you two papers of clover seed. The paper I. contains alsike seed; II., red-clover seed. The seeds are so different in appearance that no mistake should be made between them. However, neither you nor I am as infallible as the pope, but each one of us means fair business, I believe. Now, as you sowed the seed yourself, you can't help but remember whether it resembled the alsike or the red-clover seed, mailed and marked for you to-day. If you say that the seed looked like the sample mailed you in paper II., then one of our young men made a mistake, for which I am liable, and we shall credit your account with \$6.00.

Waiting for your reply we are, etc.,
JUNE 12, 1886. CHAS. F. MUTH.

COPY OF CORY'S REPLY.

Dear Sir:—Yours of June 12th is at hand. In answer to your questions, I will say, first, the seed

was not a green nor a bright yellow, as your sample of red clover sent me, but was quite dark, as if it had lain on the ground too long before thrashing, and was about five-eighths the size of your sample, and more than twice as large as the alsike got of you this spring; second, the sample of clover sent you is what grew from the seed you sent me, as sure as there is day and night. I believe I make it explicit this time. Remember, I don't question your integrity. O. A. CORY.

Frankfort, O., June 15, 1886.

You will notice that our friend Cory does not answer my questions as direct as would have been desirable. He sent me afterward an order for some goods, and stated that his clover measured 5 feet ¾ inches. I wrote him, July 24, 1886, as follows:

Friend Cory:—Inclosed find invoice and bill of lading. I have seen, more than once, alsike 4½ ft. high. It grows longer than "sapling" or "English" clover, but its stems are more slender. We therefore recommend you to sow timothy with it, so as to have something to lean against. You never saw red clover 4½ to 5 feet high, as you now say your alsike is (5 ft. ¾ inches). Seed is taken from the first crop. You can thrash it, and find the straw as acceptable food to your stock as the first crop of red clover. My son remembers most positively that the seed we sent you finished our lot of alsike of the previous season. So we are sure that it was alsike seed we sent you. I am certain that you would have told me, in reply to a former question, "The seed I sowed looked like red-clover seed," if such had been the case. You did not say so, because you are an honest man, and you really thought that yours was red clover. Alsike is a hybrid, and may not grow every time alike. Our controversy throws some light on an unpleasant experience between two friends—brother Root and brother Demaree. The latter had bought alsike seed of Root, and claimed also that it was red-clover seed which grew up. I shall accommodate both friends by writing them our experience, and I really believe that Mr. Root was no more to blame in theirs than I am in our transaction. It is the hybrid in the clover which causes the variety of growth. C. F. MUTH.

Now I must let follow, for a better understanding, friend Cory's letter of July 30th, and a copy of my reply.

Mr. C. F. Muth:—I am surprised to find a man of your intelligence and experience making the statement that alsike clover is of much larger growth than red or English. My father was one of the first to introduce it in this country, about 25 years ago, and discarded it on account of the high price of seed and its small growth, not being desirable for anything else than pasture for the farmer, of which it makes abundance, if pastured judiciously, which also improves its bloom. I am surprised, also, that it so lately produces a large red bloom, and that the stalks have reached the prodigious size of a common pen-holder, for I had always looked at it as possessing many of the characteristics of white clover. If, from your statement, the largest clover is the best proof of its being the genuine alsike, then what you sold me for alsike two years ago was no alsike, and I was fooled again; but I must say that is the way I want to be fooled, for it filled the design for which its purchase was intended. Will say, further, that its maximum growth did not exceed 15 inches, and the ground was of alluvial soil, none better; and the stems were not so fine as white clover, but not large like our common red, or sapling either. But in reading your very explicit letter, I am reminded that the clover seed you sent me was a "hybrid." Now, that makes all things plain. Am I justified in buying, and you in selling me hybrid seed for pure alsike? If you think it just, then I prefer to purchase a cheaper kind, and it may happen to prove as satisfactory for my purpose as any—I am sure as well, or better, than the pronounced hybrid. O. A. CORY.

Chillicothe, O., July 30, 1887.

COPY OF MY LAST LETTER TO CORY.

Dear Sir:—Inclosed please find receipt. Accept thanks. I have read your letter, and am surprised at the animus. I am positive in telling you that the alsike seed we sent you looked like alsike exactly, and not a bit like red-clover seed. I shall buy again for alsike seed such as we have sent you. The difference in the looks of the seed is too great

to be overlooked by an experienced hand. You *know* that the seed you sowed did not look like red clover, and *we know* that the seed we sent you looked like alsike seed. Both of our statements are truthful. This matter will not create hard feelings between us, but it should convince us that, if your statement is correct, tall and low clover is raised from the alsike seed; and we know (and if we don't we ought to know) that alsike is a hybrid plant. We have raised alsike clover for several years, and it was taller than red clover every time. A friend on the River Road, within two miles of our city limits, had alsike clover 4½ feet long. He invited me to come down and see the bees "swarm" on it, which I did. Will you tell me now that your bees, this summer, did not feed on the clover in question? And will you tell me that you ever saw red clover as tall as your alsike of this summer, which you say is 5 ft. 3½ inches long? Reading over your letter once more, I notice that you may sell the seed of that clover in question for alsike. This looks like an exhibition of good sense, for I verily believe it to be alsike-clover seed. Please send me a sample of the seed, when I will make you an offer for the lot.

C. F. MUTH.

Cincinnati, O., July 31, 1886.

Friend Muth, I can not suggest any good explanation for the difficulty between you and your customer. I will, however, say this, that quite a good many have complained that red clover came up when they sowed alsike seed; and my opinion is, that the red clover had been in the soil, and, owing to some accidental conditions that were just right for its germination, it started vigorously, while for some other reason, perhaps accidental, the alsike did not start as freely. I suggested the above explanation to friend Demaree, but he rejected it rather vehemently. A neighbor of ours sowed alsike a number of years ago, and it did not seem to amount to any thing; but several years afterward, I can not now tell just how many, by accident the ground was plowed up and every thing happened to be especially favorable for the germination of this alsike seed, and he got an excellent stand—better than is often secured when we do our best. The same thing has happened a good many times with red clover.

The seed of alsike is so unlike the seed of red clover that I do not see how anybody who has had any experience at all with the two clovers could ever make a blunder in sowing the seed. The seed of red clover is so much larger it can be easily sifted out with almost any ordinary sieve. There is no need of any admixture ever being found in the market. We have just purchased the best mill that can be found, for separating clover-seeds. This mill is to be placed in the basement of our new factory, and it is to be run by power. By means of it we expect to be able to give pure clean seed, of any of the clovers in use by bee-men.

I am afraid friend C. did not exactly understand your meaning when you said that alsike is a hybrid; that is, it is said to be a cross between the white and red clover. Now, although it is a common thing for hybrid plants and animals to revert to one or the other original parents, I hardly believe alsike is guilty of such a trick, for the reason that it has been for so many years an established variety of clover, and it is not given to sporting any more (so far as I can discover) or perhaps not as much, as different kinds of large red clover. Perhaps Prof. Beal or Prof. Cook will be so kind as to give us a hint on this matter. I should very

much like them to say whether they consider my position on the question a right one. I have never seen alsike so tall as you mention; but on very rich ground I have seen it a tangled mass of vines, perhaps fully five feet in length.

ADVERTISING; WHY IT PAYS, AND WHY IT DOES NOT PAY.

BEE-JOURNALS "REDOLENT OF WAX AND SAW-DUST," ETC.

DEAR BRO. ROOT:—Some things in GLEANINGS suggest a few thoughts, and this happens often and always; but I seldom get so far as to put pen to paper to give you the benefit, or to bother you, as the case may be. I do not report progress in business or personal matters, as my success has not been remarkable, but moderately fair. I have built up a fine apiary, in which I have great satisfaction, but have not established a trade or a name that extends very far. Here comes up the question of advertising. I have not advertised much, and I might say, as some do, that advertising does not pay. We have advertised in our county papers, perhaps ten dollars' worth, and I know of only two customers that we got thereby—two or three dollars' worth of honey sold, and more than half of that to the printers. We advertised in GLEANINGS about fifteen dollars, I believe, besides ten pounds of paper with printed heading, and some printed postal cards, the income of which is a continuous flow of circulars and price lists from those who have bees and supplies to sell, and very few inquiries from any who wish to buy. Our sales of such wares as we deal in have been to men near by whom we know personally, who visit us, and whom we visit, and who have not known of our advertising. Now, I think it unjust and foolish to turn round and blame and abuse the publisher for this. The fact is, we did not advertise enough. It is not those who make a sudden and spasmodic appearance in print that get hold of the attention of the public, and keep it, and increase and extend their business, and make advertising pay. It is those who follow up the fickle public, and take them by the button-hole by judicious advertising from month to month, who make their names and business familiar as household words; and if they are reliable, prompt, and progressive, those who are attracted to them by the printers' aid will stay with them on account of their own worthiness; and if not—not.

It may have been an error, but I decided, soon after coming to this place, that I could more profitably devote my energy to building up a strong and good apiary, and the production of honey, than to attempt much in the way of selling queens, bees, and supplies, though had I been associated with a thorough business man instead of a professional man, things might have taken another turn.

Here follows the question of bee-journals as connected with the supply-business, or wholly separate from it. This comes up once in awhile, and I have seen some publications that harped upon it continually, in a very unlovely and unhappy strain. I do not think there are many bee-papers in our country that are thus entirely disconnected, nor do I think there is any thing particularly meritorious in such a position, or any thing unfair in the opposite. I look at it from this point; It

seems to me a fine thing for a man in the supply-business to publish a price list, and a journal too, if he is able; and it usually comes to pass in that way, though some who have undertaken to issue a bee-paper apart from the supply-business have found it necessary to add that also, and to do the very thing they had so much condemned in others. I do not believe that the great multitude of *bee-keepers* find fault with such arrangements. It is, as I think, chiefly some publishers, or their sympathetic friends, who complain; and I hope I am not uncharitable in attributing to them an envious spirit.

Other things being equal, the bee-keepers prefer a paper that comes to them all redolent of wax and sawdust, of honey and the honey-comb, echoing the clang and buzz of the planer, the saw, and the anvil, the throb and jar of the press, the stir of men and women at work, and the hum of happy bees, and that which ennobles the whole, a voice of daily prayer and praise, and counsel and encouragement in general business, and in all that affects our homes and social life, in virtue and piety a helper and a guide. I say, the people, the men and women, the boys and girls, prefer such a paper and love it, while few, comparatively, would have any thing like the same interest in articles of a more impersonal style, however scientific and correct and useful, and perhaps rather theoretical than practical. D. F. SAVAGE.

Casky, Ky., Feb. 7, 1887.

A DEVICE FOR REMOVING SECTIONS FROM WIDE FRAMES.

HOW OUR CALIFORNIA FRIEND WM. MUTH-RASMUSSEN DOES IT.

THE description and picture in April GLEANINGS, of Dr. Miller's method of removing sections from the T super, as well as the same description which I had previously read in his own book, but did not quite understand until now, lead me to send you an article which I wrote for the *Pacific Rural Press* nearly two years ago, describing my device for removing sections from wide frames. As many bee-keepers, no doubt, like myself, are using wide frames, and, having once invested in them and got used to them, do not care or feel able to change for what may or may not be a better arrangement, perhaps my device may be of interest and usefulness to them. You will notice that my device operates very much like that of Dr. Miller's, only that the sections must be taken off before the wide frame can be removed. The only objection I find to it is, that the space between the guide-back and the nearest upright occasionally gets clogged with wax or propolis. Instead of hinging the uprights to the bottom-board, as mentioned in the article, to facilitate cleaning, the guide-back with guide-posts attached might be made removable for this purpose.

Against wide frames, as got from you, I have only this objection—that they are not exact, being generally too large, and leave too much space for propolizing. In many there is as much as one-eighth to three-sixteenths of an inch space between the under side of the top-bar and the top of the upper tier of sections. Next winter I shall overhaul them all and form them over a block of just the size of six sections, with merely play enough to insert and remove the sections without crowding.

In favor of wide frames, I must say that, after using them for five or six years, and gradually increasing their number, until I now have about 700, I have yet to find the first cell of brood in any section placed in a wide frame, and I do not think I could find one cell with pollen in 1000 sections. I use no honey-board, but simply have a bee-space between the brood-frames and wide-frames. I use full sheets of worker fdn. in the sections, and I find that it pays me, as my combs are perfect, plump, and full weight; whereas the first year when I used only narrow starters, nearly every comb fell 2 to 4 oz. short of a pound.

WM. MUTH-RASMUSSEN.

Independence, Cal., Apr. 18, 1887.

Below we give the article referred to:

One of the difficulties in the production of comb honey is to get the sections out of the wide frames without injury, and with as little loss of time as possible, to prevent the bees from uncapping the cells, which they will do if they are given time enough. If the separators and the wide frames could be made so exact that the former could clasp the latter and keep their place without falling off, the separators might be removed and the bees brushed off before they had time to do any harm. But such accuracy seems to be out of the question; besides, separators are now made of such thin, flimsy material that the turned-over ends have no strength in them, and it therefore becomes necessary to nail them permanently to the frames. This increases the difficulty of removing the sections, and to obviate this difficulty I have devised, and all through the present season used, the following implement, as shown in the engraving:

MUTH-RASMUSSEN'S DEVICE.

Two boards, $12\frac{1}{2}$ inches long, $3\frac{1}{4}$ inches wide and $\frac{1}{4}$ inch thick, and one board of the same length and width, but five-eighths of an inch thick, form the uprights with the thick board in the middle, and spaced so that they will slip easily through the frame, between and outside of the separators. They are joined together and held in place at each end by a strip $\frac{1}{4}$ inch thick, $1\frac{1}{2}$ inches wide, and $8\frac{3}{4}$ inches long, let into the uprights, flush with the bottom.

A one-inch dressed board, $16\frac{1}{4}$ inches long and nine inches wide, is provided with two strong cleats underneath, and to one edge is nailed a thin board, which forms the guide-back, and projects three-eighths of an inch above the uprights. To this back, and coming even with its top edge, are fastened two upright guide-posts, five-eighths by seven-eighths of an inch thick, the narrow side nailed to the board. To the two outside uprights, even with their bottom edge, and projecting inward, are nailed two strips of ordinary frame-material (not shown in the engraving). By these strips the uprights are fastened, with nails or screws, to the one-inch board in such a position that, when a wide frame is laid on top of the uprights, the bottom bar of the frame will slip easily down between the guide-back and the nearest upright.

TO USE THE IMPLEMENT.

First brush off all the bees you can, trim off any comb or honey sticking under the bottom of the frame, again brush off the bees that have come out from under the separators, then lay the frame down on the uprights, separators downward, bottom of frame between the two guide-posts, and snug against the guide-back. Now press on the

corners of the frame, alternating from the bottom corners to the top corners, and the frame will sink down and out of the way until the separators strike the two connecting strips at the ends of the uprights, and leave the sections lying free on top of the uprights, when they may be quickly picked up with the fingers and any bees remaining on the under side brushed off. And here let me say, in parenthesis, that for brushing bees nothing is better than a single large feather from the wing of an eagle or a vulture, the shaft of the feather inserted in a short piece of broom-handle, which makes it convenient to manipulate, and prevents the feather from being blown away and lost.

TO REMOVE THE WIDE FRAMES.

Place the thumbs on top of the guide-posts, and, with the other fingers grasping the side pieces of the frame, lift it out of its place.

To facilitate cleaning the implement the uprights might be hinged at the front and fastened with two iron pins at the back, but would then require a substantial bottom (instead of the two pieces of frame-material above mentioned) to prevent them from getting out of shape.

The device with the above dimensions is for wide frames holding "Simplicity" sections, as used in the "three-quarter Langstroth" hive. By making the implement one-fourth longer it will answer for the standard Langstroth frame.

Independence, Cal.

WM. MUTH-RASMUSSEN.

THE IMPORTANCE OF GIVING YOUR COUNTY.

A LITTLE STORY FROM REAL LIFE.

IF the friends who are so careless and heedless as to send orders without giving their county, as well as town and State, could see this thing as we see it, it seems to me they would make the dust fly until they could get the name of the county in which they live, printed on their stationery. Let me give you one illustration among many. A neighbor of ours purchased our forty-horse-power engine, and told us to load it on the cars and he would send directions for shipping. When the directions came they were simply "Osceola Junction, Michigan," and nothing further. Now, the Postal Guide, the railroad guides, Bradstreet's Directory, and, in fact, every thing we could hunt up on the subject, made no mention whatever of such a town as Osceola Junction; and in despair we started the car containing the engine, hoping that, when it got into the vicinity of Michigan, somebody would know where Osceola Junction was. Very soon, however, came back a telegram, saying the engine was stopped until the county could be given. Meanwhile the owner of the engine had loaded up his household goods and marked them the same address he gave us, while he went forward to make arrangements for setting up his new sawmill in the town of Osceola Junction. We could not send him any bill of lading, because we did not know where his postoffice was; but we finally found (from the railroad guide) there was a town called Osceola, in Houghton Co., Michigan; but it is a new town, and there is no postoffice established there. To make sure, we wrote to the two nearest postoffices. Pretty soon came a telegram from our friend. But even this telegram did not tell us the county either, and it was started from a point different from any of the three heretofore tried. Finally our friend was obliged to take an expensive trip from the center of Michigan

back to Medina, to find out where his engine and goods had gone to, only to learn that they had gone away up into the northwestern part of the State of Michigan, in the Grand Traverse region, while Osceola Junction is really in the central part of the State. It will probably cost him hundreds of dollars before he gets his stuff where he wants it, and gets his sawmill started—all for the want of a county!

It now transpires that Osceola Junction is in Osceola County, in the central part of the State of Michigan, and the nearest postoffice is Tustin; but the town of Osceola is located in Houghton County, in the northwestern part of Michigan, about 360 miles from Osceola Junction.

Now, then, quite a number of you have written back saucily and sometimes mad, because we told you we could not ship goods until you would tell us what county you live in; and the very worst place in the world to find is some new town on a railroad. Many seem to think, that if they give the name of the railroad and station it is enough; but if you will try shipping goods as we do, you will find it is not. Now, once more, inasmuch as the railroad companies refuse to receive goods unless the county is given, and as there are a good many towns of the same name in almost every State, we must emphatically refuse to be in any way responsible for errors in shipment, unless you give the name of the county you live in. I presume you will be astonished when I tell you that we have letters from people who do not know what county they live in; and one poor friend didn't even know the name of his postoffice—at least, he did not know how to spell it so we could identify it. If you can not do any better, ask your postmaster the name of your town, county, and State; then go to the nearest printing-office and tell them to print it on your envelopes and stationery. You can then send money without loss, and write letters, and not bother your head about any thing but your signature. By the way, I think you had better have even that printed on your envelopes and on every sheet of paper. If you would only all do it, it would save you hundreds of dollars and ever so much vexation and disappointment and ill temper.

MORAL PATENTS.

A KIND LETTER FROM THEODORE O. PEET, THE INVENTOR OF THE PEET CAGE.

SEE by April GLEANINGS that you have placed to my credit \$25.00 as a deserving remuneration, in addition to the \$25.00 paid to me some years ago for the privilege of making and selling the Peet queen-cage. This is very gratifying to me—not so much that I get the money (as at present I am not particularly in need of it, although we all, and especially bee-men, can find a place for all the dollars they can capture honestly), but it is a satisfaction to know that my little invention is appreciated and spoken of in so kindly a manner. You know I did not ask for the first \$25.00, but offered to allow you or any other man, who felt inclined, to use it and make and sell all he could; but as you insisted on paying for it, I consented to take

a \$25.00 watch, which I hold and carry to-day—the best timekeeper I ever owned, and which is a perpetual reminder to me of yourself and my own bee-life in former years, when my wife used to say I had bees on the brain. I must say, that I admire your manly way of treating the fraternity. I have been so absorbed of late years in my business in New York that I have had to drop out almost entirely from the cluster of bee-keepers; and but for the fact that I receive a call now and then from some of them I would forget all I ever knew of bee culture. But I am a good deal like the old war-horse that came to be hitched to an old dirt-cart in his latter days. When hearing a bugle-call in the street he jumped to answer it, and cart and all bounded through the streets as though charging an enemy in battle. I remember with great pleasure you and Scofield making me that little call last fall on your return from the convention, and I thank you for it, and shall, if opportunity ever occurs, return it at the Home of the Honey-Bees. I am pleased to see that GLEANINGS is still prospering, and that her *child* has grown so much like its mother that she is recognized only by the date and the juvenile department. I well remember the first issue of the children's GLEANINGS; and, if I mistake not, I put my thought in complimentary shape in an editorial in the *Bee-Keepers' Exchange*, using, as a boom, Longfellow's poem, "The Children's Hour." Well, God has blessed you, friend R., and I rejoice with you, and I give you my hand in hearty shake, and say, with all my heart, "May he continue to bless you, not only with this world's goods, but with his Holy Spirit, that you may glorify him in this life and enjoy him for ever."

THEODORE O. PEET.

Arlington, N. J., May 5, 1887.

HIVING SWARMS.

HOW LONG IT TAKES A BEE TO GO AND RETURN WITH A LOAD.

FROM the A B C book and Cook's Manual I have gained more knowledge of apiculture in one year than I should have gained in a lifetime of experience without aid from any other source. I could not think of going without GLEANINGS. Especially do I like the Home Talks and My Neighbors. I have been able to keep my tobacco pledge. It will soon be two years since I threw away my pipe. I feel better, and am able to do better mental work without it.

During the past two years, when bee-hunting, and at other times, I have carefully timed bees, and find that, on an average, they will fly 100 feet to their hive (or tree), unload, and return in 2 minutes. They will fly half a mile and back in 7 minutes; one mile in 12 minutes, and $2\frac{1}{2}$ miles in from 27 to 30 minutes. From this it will be seen that bees will fly one mile in 5 minutes. Of course, on a very windy day it would take them longer. Trips within 2 miles were made with surprising regularity.

On page 20 of his work on comb honey, W. Z. Hutchinson says that the brood-nest should not be contracted so as to be tall and thin, but should be low and flat, but he gives no reasons. I should be glad to hear them. Would it not be an advantage in increasing artificially to leave the queen and the fullest comb of brood in the old hive, on the old stand, the remainder of the contracted brood-nest

to be filled with starters only, and the super to be placed above a zinc honey-board, the remainder of the brood and combs to constitute the new swarm? By this means all the advantages of the empty brood-nest are secured, the same as in natural swarming. I should like to know, also, if it pays to hive the new swarms in an empty brood-nest, why would it not also pay at the beginning of the honey-harvest, when working for extracted honey, to proceed as above, but, instead of making a new colony of the removed brood, to place it in the super, of course using a queen-excluding honey-board. I have tried Doolittle's queen-cell protector. It works like a charm.

WILLIAM E. GOULD.

Fremont, Mich., May 5, 1887.

The facts you give us in regard to the length of time it takes a bee to go and return are very valuable, friend G., and we will try to have them embodied in the next edition of our A B C book. I have made some similar experiments, but I was inclined to think a bee would fly rather more than a mile in five minutes, unless hindered by the wind, intervening forests, or something of that sort.

THE NEW SOUTH.

THE EFFECT OF GRADUAL ELEVATION ON THE HONEY-FLOW.

THE reason that I gave last fall why this section should prove to be favorable for bees, that the sides of the mountains prolong the flowering season, seemed to be questioned by a friend in Tennessee. I would reply, that I know not how small a difference in his section would result from a very gradual slope for a long distance; but it is a fact here, that an elevation of nearly 2500 feet in 3 miles does make a difference of from 4 to 7 days (according to the weather in the spring); and to the top of "Flat Top," which towers above us 1000 feet higher, the flowering and leafing out of the trees is several days later still; so that the flowering of the top is delayed often two weeks after the trees in the valley. This prolonging of the flowering season I consider constitutes the slope of this mountain ridge a desirable place for bee-raising, besides being adapted to most of the varieties of fruits. Pure air, the best of water, a mild climate, cheap land, good soil, and low taxes, are reasons enough to invite industrious and enterprising farmers and apiarists to come and settle. As some proof, in 1850 Virginia reported more honey and wax than Ohio; and in 1860 she raised almost as much; but since the days of improved hives, of course Ohio has taken the lead. Bring this same enterprising spirit into the South, and I see no reason why she should not again equal if not surpass the North, having longer summers and shorter winters. I am not a bee-keeper. It is only because I am fully occupied otherwise; but I am not the less an interested reader of GLEANINGS. In fact, it is my preference of all the fourteen papers I take. I could heartily wish its subscription-list were 70,000 rather than 7000. Now that I am telling my likes, it will not be transcending the department of "home interests" if I name the next best. It is the *Sunday-School Times*, published weekly at 1031 Walnut St., Philadelphia, Penn., 11 by 15 inches, 16 pages. To new subscribers, \$1.00 per year. Though intended mainly to explain the

Sunday-school lesson, with articles from about fifteen different authors, it has other practical subjects; but, as I take it, it makes the best Sunday reading, especially where one does not have a chance to attend the preached word. I must not forget to state, that of the mountain slope some of it is steep and rocky, but the most of it can be plowed, and there is but very little that is not suitable for fruit-growing. There are two or three cheap properties for sale now; and since the South has taken such a new start forward, it will not be long before prices go up here as they have in Georgia and Alabama.

A. H. VANDOREN.

Mons, Bedford Co., Va.

THE SINGLE-TIER VS. THE DOUBLE-TIER CASE.

THE DECISION OF THOSE MOST COMPETENT TO DECIDE.

AS there seemed to be a little variety of opinion as to whether the double-tier shipping-case is preferable to the single-tier case, or vice versa, we submitted the matter to those who quote prices on honey in GLEANINGS. We accordingly sent them the following note, together with a list of questions to be answered:

Dear Sirs:—As you quote prices regularly in our journal, GLEANINGS IN BEE CULTURE, we take it for granted that you are competent to decide what kind of a comb-honey shipping-case sells best with you. We shall therefore be very greatly obliged if you will answer, briefly, the following questions, as we desire to publish the same, together with your replies, in GLEANINGS:

1. Do you prefer the single or the double tier shipping-case for retailing and shipping comb honey? In other words, which kind of shipping-case is the most salable, and the most easily handled—the one having only one horizontal tier of sections, or the one having two horizontal tiers of sections? Please give your preference in either case, and your reasons therefor.

2. Do you prefer to have the shipping-case glassed on one or both sides, and why?

3. What size of shipping-case do you recommend—that is, in your opinion how many pounds of honey should they hold to sell the most readily?

By answering the above questions you will not only confer a favor upon bee-keepers, but a benefit to yourselves as well. What we want is an expression from those most competent to decide in this matter of shipping-cases, in order that bee-keepers may crate their honey according as the market seems to demand.

Very truly yours, A. I. ROOT.

1. We prefer the single-tier. It is less liable to damage by leaking.

2. One side, because we believe in selling as little glass as possible.

3. Twenty to 24 lbs. CLEMONS, CLOON & CO.
Kansas City, Mo., May 7, 1887.

1. I prefer the single-tier shipping-case. It has all the advantages of any other, and none of the disadvantages.

2. Glassed on one side is sufficient; and, indeed, I am of the opinion that it has advantages over double, or two sides.

3. For trade in general, crates should contain 12 to 24 lbs. each. R. A. BURNETT.
Chicago, Ill., May 9, 1887.

1. We prefer single-tier shipping-cases. Honey

carries better, and is easier to take out of the cases, and is preferred by retailers.

2. In regard to glass ends, it does not make much difference, if honey is packed straight, whether one or both ends are glass.

3. Twelve and 24 lb. cases suit our market, as they are lighter to handle, less liable to breakage, and are more convenient for family use; 12-lb. packages are usually sold in cases as they are. Parties in putting up honey should be careful to mark their packages correctly—gross and tare, especially the tare. The gross weight we can get if omitted.

W. B. WESCOTT & CO.

St. Louis, Mo., May 7, 1887.

1. We have handled two-tier shipping-cases from the beginning of the time when comb honey was shipped to our city in quantities and in good style. As soon as some of our enterprising friends commenced to ship us single-tier cases, we found that honey would arrive in better condition, and was, consequently, of better sale. We are decidedly in favor of single-tier honey-cases which hold no more than 24 one-pound sections, or more than 15 two-pound sections. If they hold less, it is nothing against them.

2. They should have glass on each side, not on their ends, so that the most part of the contents of the case is exposed to view.

CHAS. F. MUTH & SON.

Cincinnati, O., May 7, 1887.

1. I very much prefer the single-tier case for shipping and retailing honey, as it is much more safely shipped, and not so liable to be daubed with honey from broken sections; and on account of its smaller size, customers will often take a whole crate when they intended buying only a few pounds, and I think they show off honey to better advantage, and are always the first to be sold when side by side with the double-tier in commission-houses.

2. I also prefer glass on both sides, as I think it helps the sale by helping the appearance.

3. The size that gives the best satisfaction in this market holds 12 one-pound sections.

M. H. HUNT.

Bell Branch (near Detroit), Mich., May 10, 1887.

1. I prefer the single-tier case. It is more salable, easier to handle, less liable to break, and the bottom tier is not soiled by leaking.

2. I prefer my shipping-cases glassed at the ends; the glass being smaller, it is less expensive, and not so liable to break.

3. Small cases sell best from 12 to 24 sections, $4\frac{1}{4} \times 4\frac{1}{4}$.

The importance (in my experience) of glass is this: I had about 2000 lbs. shipped by freight, in cases that could be easily seen, which came through in good shape, in cases holding 50 lbs. Again, I had 600 lbs., in cases of the same size, with one small glass about 3 inches square in one end, and could not be easily seen. The honey was about two-thirds broken down, and the rest badly soiled. That is my reason for single-tier cases, well glassed.

EARLE CLICKENGER.

Columbus, Ohio, May 9, 1887.

1. We have no decided preference; have handled the single and double tier crates largely, and found good demand for both. We would rather indorse the double-tier crate for one important reason;

namely, a dealer, purchasing or ordering honey, will just as readily take a large crate as he would a small one. This way more honey would be disposed of at less expense to the producer.

2. We prefer to have the crates glassed on both sides (provided the sections are unglassed), as the honey will show up to better advantage, besides improving and adding to the appearance of the crate.

3. For a single-tier crate, we prefer the crate to hold 24 or 25 combs, either 4x6 or 5x5.

For a double-tier crate we would recommend a crate to hold 32 combs, 16 to each tier, 4x4, showing 8 combs on each side. We can not indorse a larger crate; for instance, one holding 48 combs, as it is too heavy to be handled carefully while in transit.

H. SEGELKEN,
Manager of Honey Dep't of
THURBER, WHYLAND & CO.

New York, May 9, 1887.

After receiving the replies above, and as the answers seemed to favor the single-tier case, we wrote to Dr. Miller, knowing that he rather preferred the double-tier case, and requested him to give his preferences, and briefly how to construct the case. His answer appears below:

1. The double-tier shipping-case has the objection that there is danger of injury to the lower tier of sections by the upper tier resting upon them. It also presents a bad appearance, to have the bottoms of the upper tier and the tops of the lower tier show in the center of the glassed side. These are the two principal objections to the double tier; but by putting a bar across the middle of the glassed side, and using, instead of a single piece of glass, two pieces of the same size as are used in the single-tier cases, the second objection disappears. The first objection is removed by using a false bottom between the two tiers, so supported that no weight comes upon the lower tier. We have, then, in favor of the double tier, less cost per section, and a finer appearance when piled up, as a greater proportion of glassed surface appears in the double-tier pile. Thus the double tier has the preference.

2. On one side, as it shows just as well and costs less.

3. Twenty-four one-pound sections.

Marengo, Ill. C. C. MILLER.

CALIFORNIA.

HONEY-YIELDING PLANTS AND TREES OF ELDERADO COUNTY.

OUR honey season in Eldorado County commences about the first of February, and ends about the last of June. July, August, and September are the dry months. In October the fall flowers commence to bloom, and continue in bloom until about November 15th. The first thing that the bees work on here is the willow, from which they obtain a great amount of pollen. Manzanita commences to bloom a few days later, and continues to bloom for about six weeks. Manzanita is a pretty good honey-yielding bush. I never saw a season yet that bees did not work on it. Chaparral is next in bloom after manzanita. Bees worked pretty hard on chaparral this season. California lilac commences to bloom after chaparral. There are five or six different species of California lilac, all of which are good honey-yielding

bushes. California lilac is the most important of all the honey-yielding bushes of the Sierras.

Maples, dogwood, wild cherry, and plum are good honey-yielders. There are several species of wild clover which the bees work on. The most important one is Indian clover. About the 15th of March, madrona commences to bloom, and continues for about two weeks; bees work very hard on it some seasons. Sometimes thousands of bees are at work on a single tree.

Poison oak, sage, pennyroyal, and cardinal flower are good honey-yielders. Folocio commences to bloom in May, and continues until the last of June. It is the best honey-plant that we have here. California lilac yields more honey, but it is not as good. The honey from folocio is of a beautiful straw color, and weighs about 11 lbs. to the gallon. Holly, buckeye, and wild coffee are good honey-bushes. In July and August, bees do not work much—just enough to keep out of robbing each other. Mints, smartweed, and hartshorn bloom in the fall. Hartshorn yields considerable honey. Italian bees stored several pounds of honey from it while the black bees did nothing. S. L. WATKINS.

Grizzly Flats, Cal.

HOW I DISPOSED OF 4600 POUNDS OF HONEY.

SOME GOOD SUGGESTIONS FROM G. F. ROBBINS.

FRIEND ROOT:—I have about finished my crop of honey for 1886, and now shall I tell you how I did it? When the gathering season closed and the marketing season opened, I had gathered in what I had carefully estimated at 4600 lbs., of which 3050 was comb honey and 1550 was extracted. Squads of honey had been raised, and city and village markets were alike glutted. How I should dispose of this, the largest crop I have had, with more competition in a day than I had ever had before in a week, was the problem. This is how I solved it:

1. I got one or two merchants in the three villages near, to sell for me. They did from a little to nothing for me. They sold for me about 250 lbs.

2. I worked my home market by personal effort for all it was worth. No one, to whom I thought I had any chance of selling, escaped me. I was more successful. I sold nearly 800 lbs. in this way. Much of this patronage was secured in exchange for work and various commodities—nearly half, perhaps, in which no money was handled.

3. By corresponding with parties in Kansas, with whom I had had some business or personal acquaintance, I sold 430 lbs. Another man in that State ordered, through a relative here, 115 lbs. of extracted honey.

4. I canvassed the hotels of Springfield. At only one did I succeed in making a sale. That concern took in, at different times, nearly 200 lbs.

5. I worked, when convenient, with private parties in Springfield, including business men. I even tried peddling a little, commencing with reluctance and quitting with disgust. My efforts in these directions were the most barren of all. I sold in that way, and traded, about 175 lbs.

6. I shipped about 635 lbs. to Cincinnati, about the holidays, in 48-lb. cases. It was the finest of my honey—the very pick. But being in large cases it seems to have dragged along until in March, when I

was willing to settle up at 9 cts. per lb. for the lot. It netted me less than 8 cts. I shall not ship much more at that rate.

I worked hard among the groceries of Springfield. They took something over 1600 lbs. Here was the field of battle. Here I wrestled hard for prices. Generally I either compromised or surrendered. I had to. The Muth 2-lb. honey-jars took fairly well. All I sold to grocers, of extracted honey, some 600 lbs., was in this shape. I realized from 10 to 12 cts. for comb honey, and about 8½ cts. for extracted. I got 12 cts. at the hotel. To private parties I charged 14 cts. for comb, and 10 cts. for extracted. At home my price for nice comb honey was 12½ cts. Competition compelled me to come down to that. I sold extracted at 8 and 10 cts. For broken and some very inferior comb honey, I got 8 and 10 cts. I obtained 13 cts. for the comb honey I shipped to Kansas, and about 8½ cts. for extracted, packages thrown in. I shall try that kind of shipping again.

I gave away about 125 lbs. to relatives, brothers chiefly. All this foots up to about 4150 lbs. Allowing 50 lbs. for leakage and shrinkage, there are some 400 lbs. yet unaccounted for. What became of that? Why, bless your heart, we ate it.

You see I have worked hard to sell my honey to advantage. I did not pack it up and lump it off to a big city, and take the chances. Yet one will have to produce cheaply indeed to make a living at even the prices I obtained. My sales footed up to \$422.85. I obtained about \$22.00 for beeswax — in round numbers, \$445 from 57 stands of bees in a flush season, with glutted markets, or less than \$400 net.

GEORGE F. ROBBINS.

Mechanicsburg, Ill., May 5, 1887.

SWARMING, ETC.

SOME SEASONABLE HINTS FROM G. M. DOOLITTLE.

PICKING up a bee-paper lately I found this statement given by quite a prominent apiarist, regarding swarming: "If we allow bees to swarm they will cast their first swarm on or about the commencement of the honey season; and in about twelve days we may expect the second swarm; and in four days more the third. I think this is the average time of swarming; therefore it is sixteen days from the time the old queen leaves the hive with the first swarm until the third swarm issues." Having allowed natural swarming in my apiary during all of my 18 years of bee-keeping, and believing that the above is not correct, also knowing that much of the interest of bee-keeping hovers about the natural swarming of bees, I thought I could please the readers of GLEANINGS no better at this time, just as swarming is about to commence in the Middle and Northern States, than to tell some facts as I find them, relative to when swarms may be expected.

To the beginner this is a matter of much importance; for by them, hours and days are spent needlessly in watching bees, which a little knowledge of the matter would save, as well as to do away with much anxiety in the matter. As to when the first swarm of the season will issue, be the apiary large or small, I have never known it to fail that such a one came with the sealing of the first queen-cell, this being the rule with all swarms; but after

swarming gets under headway in a large apiary, especially with the Italian bees, some swarms issue without any preparation for swarming at all; others, when eggs are laid in queen-cells, etc.; but I never knew such a case with the first swarm of the season. Understand, I do not say that a first swarm of the season never did issue without this preparation, but only that I never knew one to do so. Then we have the sealing of the cell as the indication of a first swarm. Now, all persons familiar with queen-rearing know that the time the queen remains sealed in the cell does not vary much from seven days; hence in seven days after the old queen leaves with the first swarm, the first young queen is hatched. If a second swarm is to issue, this queen begins to peep or pipe when from 6 to 8 hours old. If she commences to peep I never knew a swarm to fail to issue, unless the object of the bees was thwarted by the keeper or exceptionally bad weather. This piping is kept up for from 36 to 45 hours, when, unless kept back by foul weather, the second swarm issues.

An item worthy of note is, that the weather must be very bad to keep after-swarms from issuing, for they often issue on cloudy days, or on the least streak of sunshine in a rainy day. Then, again, they come out at all hours of the day, from five in the morning till seven at night, while the time of issuing of first swarms is usually between 9 A. M. and 4 P. M. Then, as a rule, all second swarms may be expected in 9 days after the issue of the first swarm, instead of 12, as our friend quoted tells us. If the bees conclude to swarm still further, after the second swarm has issued, another queen is allowed her liberty while the rest are kept confined in their cells, being fed through holes in the cell, so they are virtually of the same age and strength as the one which has her liberty. The queen let loose at once begins peeping, keeping it up for about the same length of time the others did, so that the third swarm comes two days after the second, or 11 days after the first. If a fourth, fifth, or sixth swarm issues they come out the next day after the third, and each other, so that, should the sixth swarm issue it would come on the 14th day after the first. Five swarms is the highest number I ever knew cast from one colony during our swarming period; but I believe as high as six have been reported.

As I believe all after-swarms are a disadvantage, I wish to tell the reader, before closing, what I consider the simplest way of stopping them when the first swarm is hived on a separate stand, instead of on the Heddon plan. If the first swarm issued according to rule, the first young queen will be hatched in 7 days, and, unless prevented, lead out a second swarm on the 9th day. Taking advantage of this fact I wait 8 days after the issue of the first, when the hive is opened and all the queen-cells are cut off, when we have a sure thing in the matter, which can not be said regarding any other plan dependent upon the cutting of queen-cells. Where a person has not too many hives I find it as good a way as any to listen for peeping in the evening after it is thought a young queen has hatched; and if the queen is heard you are certain of her presence among the bees. If not heard, then listen the next evening, and so on till she is heard, when you know you are safe in cutting all cells. In cutting these cells it is well to shake the bees off the combs or else you may fail to see all of them, in which case, if one remains a swarm is sure to issue.

This article is written mainly for beginners, for all of the older heads have established plans of one kind or another, which—ahem!—are probably any of them better than the above. If so, won't they tell us about them? G. M. DOOLITTLE.

Borodino, N. Y., May, 1887.

THE T TINS.

THE NEW MACHINE FOR MAKING THEM.

WHEN the T tins were first made they were simply two L tins soldered together thus:  in fact, this was the only way  in which they could be constructed with ordinary tinner's tools. As soon as there was a demand for the T super, it became evident that the T's must be made of one piece of tin. However desirable this might be, there was the difficulty of bending the T's out of one piece of tin. We studied on the matter for some time, and finally Mr. I. R. Good, of Nappanee, Ind., said he would sell us the T-tin folder which he had constructed. We told him to send it on, partly because we needed just such a machine, and partly because we were curious as to its construction.

Before we describe the machine itself it will be necessary to explain how the T's are bent, and we will therefore refer the reader

to the diagrams below, all of which are full size.

THE T TIN AND HOW MADE.

We first cut out a lot of tin into strips $1\frac{3}{4}$ in. long and $1\frac{1}{8}$ in. wide. A quarter-inch fold is made on each side of the tins, as in Fig. 1. While the gauge of the folder is set we will fold all the troughs we need. So far, common tinner's tools are equal to the requirements. It is now necessary to bend Fig. 1 at the point *y*, into Fig. 3. In order to bring the fold to the right place it will be necessary to have some sort of a projection, as in Fig. 2, shown by the heavy black line. This projection should be held firmly, for the folding of the tin produces considerable strain. We next want some kind of device whereby we can easily, quickly, and accurately make the fold at *y*. To illustrate more clearly, we will suppose that we have procured two boards whose double thickness is such that they will slip snugly between the folds in Fig. 1. They should be hinged at *y*. Now, then, having the metal projection as in Fig. 2 secured in the proper position, we simply open the two hinged boards as we would the covers of a book. When nearly half open, the T

tin will be bent as in Fig. 2; finally it assumes the form of Fig. 3.

This is, in fact, precisely the manner in which our new T-tin folder operates, a cut of which we give below. It is represented as in the act of bending a tin which is now bent as in Fig. 2, below. F and G are two cast-iron frames hinged on the sides, as shown, so as to revolve on the line at A. The lower iron frame G is also hinged to a piece of plank at the opposite side. A strip of heavy strap iron (the purpose of which was described and is represented in Fig. 2 by the black line) of the length of the machine is screwed on to the piece of plank upon which the frames rest below A, as shown. It projects just high enough to make a $\frac{3}{4}$ fold, as illustrated in Fig. 2, and should then be on a level with the crack between the iron frames.

To operate, grasp the lever shown on the left; press downward so that the front side of the two frames is raised above the strip of strap iron. Hold the lever down until you can pick up a trough as H, and slip it on to the rabbeted edge, which is just wide enough to allow the trough to fit snugly. Release the hand from the lever, permitting the point A to drop into position. The strap iron is now just right to make the fold at *y*, Fig. 1. Now with the right hand grasp the handle C. When revolved as in the engraving, the tin A is folded as shown in Fig. 2. While C is revolving, the foot should press on the treadle attached to the rod B, to hold the frame from slipping above the strap iron. When C is revolved to E, the tin is bent into Fig. 3. The lever is now grasped, a downward motion frees the frame from the strap iron, when the T tin can be slipped off and thrown upon the pile E.

The machine friend Good sent us, although made of wood, did not differ substantially in principle from the iron one we have just described. We found, however, that where a large quantity of tins is desired, wood is hardly firm enough to stand the strain of folding, hence necessity compelled

GOOD'S T-TIN FOLDER, WITH OUR IMPROVEMENT.

us to make one of cast iron, as shown above. One who desires to fold T tins sufficient for his own use will find the wooden machine ample for all his purposes, and we will fur-

nish it complete for \$3.00. On the contrary, a supply-dealer will need an iron machine as above, and we will furnish it for \$10.00.

With either of the above machines you will need a common tinner's folder, and, for that matter, a tinner's squaring shears, to make the tin troughs as in Fig. 1 and H. Moreover, it will be absolutely necessary that the tin be cut up into strips accurately, and that the folds be made perfect. If you purchase a T-tin machine you had better instruct your tinner to make the tin troughs. Home-made machinery, which you might be able to construct for the purpose, would not generally be accurate enough.

In this connection I may mention why we prefer to have our T tins made as in Fig. 3 instead of as in Fig. 4. It has been found by experiment, that where the upright of the T is not pressed together tightly, as in Fig. 3, it will be a great deal stronger; consequently we make all our T tins like Fig. 3.

KRETCHMER'S T-RAIL SECTION-CASE.

HOW CONSTRUCTED, AND SOME OF THEIR ADVANTAGES.

THE illustration below will be recognized by many bee-keepers of the West, it being the T-rail section-case, composed of two horizontal rims, or hoops, arranged for two-pound sections, first illustrated in 1880. In order to space the sections correctly, the upright stem of the inverted T rail is made of wood, while the horizontal part is a strip of tin, fastened to the upright wood, making a stiff T rail which supports the sections *K*; separators, *I, I*, are set between the sections, resting on the T rails; a wedge, *O*, within the beveled case, clamps all closely, while a Simplicity half-story covers the exposed part of the sections, with proper bee-spaces above and below, as they may be tiered up and alternated.

THE T-RAIL SECTION-CASE.

About the year 1879 I constructed the same style of section-case for the one-pound, or $4\frac{1}{4} \times 4\frac{1}{4}$ sections, with the T rails made of two pieces of tin, which has since been improved, and of which I give the following illustrations:

SECTION-CASE FILLED AND CLOSED.

SECTION-CASE OPEN; PART OF SEPARATOR H BROKEN AWAY.

This is composed of two horizontal rims, or hoops, *F, F*, beveled on 3 sides from the center to the outer edge (the side opposite the wedge being straight); adjustable tin T rails support the sections; any width of the $4\frac{1}{4}$ section may be used. Separators, *P*, may be set between the sections, resting on the T rails; a wide wooden separator, *H*, closes the ends of each row of sections, which also prevents the sections from being attached to the case; and a double-beveled horizontal wedge, *O*, presses all sections tightly. The pressure, being near the center, holds the sections square, with equal pressure at both top and bottom. This pressure leaves no space for deposit of propolis. The inside bevels of the case assist in adjusting the sections; the last sections can be inserted or removed as readily as the first one. The upper rim of the case is beveled exactly like the lower one, and slips readily over the sections, while the upper unbeveled edge holds the sections tight and close, like a hoop on a barrel. These section-cases are invertible, and may be alternated and tiered up, with a bee-space at either top or bottom, at pleasure.

As the case is made of two equal hopper-shaped rims, the sections may be removed therefrom *either side up*. We simply lift off the rim that is uppermost, draw the wedge, and any or all sections may be removed in the easiest possible manner; none are cracked or broken, none are attached to the case; and, being wedged, no room is left to propolize the edges.

These cases fit *inside* of any Simplicity or L. hive now in use, sitting either directly on the top of the brood-frames, with or without a honey-board under it, or can be made to fit even with the outside of any hive. In the construction of this case, as above described, strips of boards full $2\frac{1}{4}$ inches wide (usually too narrow for other parts of the hive), are first ripped slanting in two, thus forming the upper and lower part, and beveling them at the same operation. Where the bee-space is desired above the sections (as shown in one of the illustrations), we cut on the inside a saw-kerf $\frac{3}{8}$ from the upper edge all around. Into the end pieces we slip strips of tin, and nail through it, securing at once the proper distance. Projections from the T rails enter into the grooves cut into the sides, and in which they are movable, to either the $4\frac{1}{4}$ or 6-to-L-frame sections; and by it, the upper T rails are removed with the upper rim; or, if loose T rails are desired, a piece of heavy tin, $\frac{3}{8}$ inch square, is inserted and nailed into this groove, which supports the rails, securing proper distance and uniformity. E. KRETCHMER.

Coburg, Montgomery Co., Ia., May 9, 1887.

Your arrangement is quite ingenious, friend K.; and, as I have said before, if we were really satisfied that it is advisable or desirable to reverse our sections, your plan

would be, perhaps, one of the simplest arrangements that can be devised. We do not notice any arrangement to clamp the hopper-shaped rims. F, F, together, but perhaps none is needed.

HEADS OF GRAIN FROM DIFFERENT FIELDS.

SWARMING OUT IN MAKING ARTIFICIAL SWARMS.

I DIVIDED a hive for a neighbor, and every thing went on nicely until the queen hatched. She destroyed all the cells and swarmed out the next day, taking with her about half of the bees. I was not there when they swarmed, but came along about six hours after. He had managed to hive them nicely, and left the hive about 30 feet from where they settled. The bees were passing from one hive to the other at a rapid rate, but were quiet. I examined the hive they came from, and they had not a queen. I took them back to their old home, put them in, and in a few minutes they were all quiet. What I do not understand is, why the young queen should swarm out. It was not for the want of honey, for they were in a new hive, and every thing was tidy, and they had some brood.

WHY THE BEES DID NOT WORK IN AN ARTIFICIAL SWARM.

I also divided a hive and put in a queen-cell. The bees would not come out when the entrance was open, and would have stayed there and starved had they not been fed. After the queen was 24 hours old they began to stir out a little. They seem to be doing nicely now. They had plenty of bees to keep the brood warm, and work at the same time. Why did they act in such a manner? J. F. BLENETT.

Smithville, Monroe Co., Ind., May 16, 1887.

Friend B., it is a little hard to tell why the young queen swarmed out the next day after she was hatched. Such things sometimes happen in making artificial swarms.—In regard to the worker bees that would not go out of the hive, it was because they were not yet old enough. When you divide a colony, the flying bees will almost always go back to their old stand—that is, if the old stand is not moved at all. Consequently no stores will be brought in until these young bees are old enough to take their flight, and go to work. In such cases, unless there is honey in the combs, they are liable to starve right in the height of clover or basswood bloom. The only way is to feed them until they get old enough; but a better way is to do your dividing in such a way that you will have at least a few working bees that will stay in the nucleus. See directions for dividing, in any of our text-books.

RELATIVE AMOUNT OF STORES CONSUMED IN OUT-DOOR AND CELLAR WINTERING.

On page 892, 1886, Dr. C. C. Miller asks, "Does cellaring lessen the vigor of bees?" Having experimented on that point, also as to the amount of stores saved, I give you my figures. Nov. 20, 1885, I put in the cellar 76 colonies and left 6 good strong ones on their summer stands in double-walled hives, with $\frac{3}{4}$ -inch dead-air space and 5 inches cut straw over the frames. I weighed all the same day. Apr. 20, 1886, I took the bees from the cellar, and weighed all again. To make the average a fair one, I took

the weight of 37 of the best colonies from the cellar against the 6 wintered out. The 37 in the cellar consumed 9½ lbs. each; and those out, 13 lbs. each. To sum up, cellaring increased their vigor, and in 5 months used 26 per cent less stores.

Albion, N. Y.

G. H. ASHBY.

CAN OLD MOLASSES-BARRELS BE USED FOR THE STORAGE OF HONEY?

How would it do to take syrup-barrels, say those such as we get 6 or 10 lbs. of syrup in, wash them out and put extracted honey in them? Would it injure the honey in any way? I don't intend to ship the honey in them, only I want something to answer the same as a tank. If they can not be got clean enough by washing with water at the bung-hole, I could knock one head out and then cover them with a cloth and lid. If they won't injure the honey it would be a big saving, as I can save the barrels when I empty them of syrup for the honey season. They do not cost me any thing, and they will hold about 600 lbs. apiece, and 10 of them will hold the amount that I would want a tank to hold. I am told that such a tank would cost me 20 or 30 dollars. I have so far been keeping my honey in the largest stone jars, also in large tin cans; but they are too expensive. If you have had no experience in putting honey in such barrels, or can't answer it to a certainty, perhaps some of the readers of GLEANINGS can. C. M. HICKS.

Fairview, Md., Feb. 14, 1887.

Friend H., there is no way to make molasses-barrels, or wooden barrels of any kind, keep honey as nicely as tin cans or stone crocks, unless they are coated with wax or paraffine, or something similar. You may wash the wood ever so clean, and dry it ever so dry, and when it becomes soaked with honey the wood will give the honey more or less of a woody flavor; and where the barrels have been once used for molasses the honey will be sure to have a molasses taint. I would not undertake to use them without waxing them, according to the directions in the A B C book. You might try one or two, to see if you do not find it as I state.

HONEY MADE BY FEEDING SUGAR.

I inclose an advertisement which I cut from one of our local papers. You will notice what a pretty insinuation it contains regarding our "Northern" honey. Perhaps some of the readers of GLEANINGS can tell us a little something of this extensive or celebrated bee-farm. CHARLES H. SMITH.

Pittsfield, Mass., April 30, 1887.

NOT ONE FLAKE OF SNOW.

And over 300 different varieties of flowers in bloom all winter long, at

DR. D. R. FOX'S CELEBRATED APIARY, OR BEE-FARM (of 400 hives), Jesuits' Bend, La. His Northern agent has just received 1000 lbs. of this pure extracted orange-blossom honey, fresh from the apiary. This honey is as fine flavored as any ever introduced into Massachusetts, and is warranted strictly pure it being gathered from nothing but flowers and has a much nicer flavor than Northern honey made by feeding the bees on sugar. Samples of this honey can be found in all the leading grocery stores in Pittsfield and vicinity.

Thanks, friend S. To be sure, we want to know all about Dr. D. R. Fox, of Jesuits' Bend, La. But is it not possible, and altogether likely, that it is the advertiser in your town who is responsible for these slurs, and that friend Fox knows nothing of it? In any case, however, he should be notified that he is reflecting on good and honest men. Perhaps some of our readers can tell

us more about it. If they don't have one flake of snow, they do sometimes have serious frosts, even in sunny Louisiana.

CUCUMBER PEELINGS FOR DRIVING OFF COCK-ROACHES.

D. C. McLeod, of Plena, Ill., asks for a remedy for cockroaches. Years ago it was asserted by some bee-keepers that the roaches do no harm. As they were then numerous in some of our hives, I watched them and found their habits really predatory; but it seemed impossible to exterminate them. When pursued they will dart from comb to comb and from cell to cell with astonishing rapidity, and never seem to cease incubating, winter or summer. At that time I could find no remedy, but have since been assured, by several, that the thin peelings of green cucumbers placed on the frames will utterly destroy them. You might try it, friend McL., on a small scale at first, to find if it injures the bees, and be sure to report progress to GLEANINGS.

W. A. J. BEAUCHAMP.

Orange, Tex., Apr. 23, 1887.

Friend B., I can not have very much faith in any remedy that does not seem to have either reason or sense about it, and I can't see why cockroaches would not eat cucumbers as well as their natural food. If the cucumbers were to have some Paris green sprinkled over them, or something of that sort, there would then be something rational in the proceeding; but as this Paris green might kill the bees too, I presume that will not do.

A NOVEL WAY OF GETTING A GOOD PRICE FOR HONEY.

I went into winter quarters with 72 colonies, lost 5. Last year I raised 1300 lbs. of extracted honey, and sold it for 8 cts. per lb., or 15 lbs. for one dollar. I raised 1500 lbs. comb honey, and sold it for 10 cts. per lb. You may think that too cheap, but I think it better than raising wheat at 75 cts. a bushel. I know it is. Now a little about the way I sell my honey. One year ago last winter I built me an ice-house and cooler, that I can keep eggs in. It cost complete about \$75.00. About the first of last Aug. I set my extractor on the spring wagon, filled it with honey, put on about 2 egg-crates and some comb honey, and away I went. Last year eggs were from 8 to 12 cts., while I peddled, and traded honey for eggs. I kept my eggs until Nov. 1, and sold them for 18½ cts. So you see I got a good price for my honey after all. I have room in my cooler for 3000 or 4000 dozen, and expect to fill it next fall in that way. I can sell about 2000 lbs. of honey in two weeks.

Sebewa, Mich.

H. M. BROWN.

Friend B., your suggestion is an excellent one. Your cold-storage room keeps the eggs in good order from August 1st to November 1st, after which little or no ice will be needed. If you succeeded in making such a cold-storage room for \$75.00, you did extremely well.

A PLEA FOR HIVES ON LEGS.

I have come to the conclusion that the best way to winter bees is *outdoors* on their summer stands. The past winter has been a pretty severe test for the "little fellows," at least in this neighborhood; and yet I never have wintered bees so successfully; in fact, I think they came through stronger, if any thing, than they were last fall! During summer

and winter my hives are set on a bench about 1½ feet from the ground, thus avoiding one great objection to bee-keeping—stooping. I can imagine some skeptical bee-keeper mentally asking me this question: "Would not the frogs and toads of the neighborhood become fat over the weary, heavily laden bees who missed the entrances to their hives?" My answer is, most emphatically, No; not if you do the way I do—scatter a little coal-ashes round about and under the hives; leave no hiding-places for the pesky "frogs and toads;" that's the idea. Try this, and I'll warrant that you will soon declare my "old, but good" plan the best. Where the hives are up so high it is a good plan to have a "windbreak" of some kind on the windward side of the apiary. Since I began wintering bees by this plan I have never lost a colony. W. M. BARNUM.

Angelica, N. Y., May 7, 1887.

WILL THE SCENT OF MICE ON SECTIONS OTHERWISE UNINJURED PREVENT BEES FROM OCCUPYING THEM?

I have quite a lot of old sections with foundation pulled out, ready for work, which were left over from last season; but as I had no honey-house, they were left where the mice could have access to them. They are not eaten by mice, nor in any way spoiled, only the scent, perhaps, where they have run over them. Now, I have been told by an old bee-keeper (how much he knows I can't tell), that bees will never work in sections or comb that mice have run over, and I do not want to lose the time in experimenting, to see if it is the case. Supposing you know, I thought I would find out at once. It will be a great loss to throw away all of my old sections with comb in them, but I suppose I had better do that than lose all. GLEANINGS has just come; and to say that I value its aid, and that it is one of my most welcome visitors, would be but expressing things mildly. I never expect to try to do without it while I keep bees. L. S. HAINES.

Greenville, Ill., May 3, 1887.

Your informant is entirely wrong, friend H. We have had hundreds of brood-combs eaten into more or less by the mice, and have put them into hives, and the bees took hold of them and filled up the holes as promptly as one could wish. They also have the knack of entirely removing the odor of mice; for when the combs were put into the hives, with the peculiar mouse smell (which is decidedly offensive to me), at the expiration of 24 hours, or about that time, the bees had cleaned out the combs and put in new pollen and honey. The offensive odor had disappeared entirely, and the combs smelled as sweet and clean as if they had always been in the bee-hive. I have never tried it for sections, because we never let the mice get into our comb honey; but I think the bees would fix the sections up all right, sweet and clean, if you thought best to set them at it.

SEALED COMBS OF NATURAL STORES VS. FEEDING GRANULATED SUGAR, ETC.

As we have wintered our bees successfully the past winter, we will present you with a few thoughts on that subject. During the first five years of bee-keeping we always set aside sealed combs of best clover honey, and scarcely knew a loss from wintering during that time. But so many of the leading bee-keepers declared in favor of

sugar stores, we became induced to feed largely of granulated sugar, but have lost a great many colonies so fed. Last season we returned to our old practice of saving sealed honey for stores; and the result is, we have lost but two out of fifty put in the cellar. Now, if all would practice this method instead of feeding sugar, how much honey would be taken from the city markets, thereby raising its value that much! On this matter of using honey in every way we can, and in developing the home market, depends the future price of honey; and to illustrate what I have said in another article I will give you a case in point. Mr. P.'s apiary of 80 colonies is five miles from us. Mr. H. lives within 20 rods of Mr. P.'s house and apiary. On one of our trips we saw Mr. H.; and by showing him some fine clover we took his order for \$5.80 worth. Mr. P. saw us deliver it, and hailed us with "How did you sell that man that honey? He has lived here for years, and I have never sold him a pound." I asked Mr. H. how this was, and he replied, "He never offered me any." Our books now show that we have sold Mr. H. three times since then, to the amount of \$18.00, but have never sold him a pound except when we offered it to him. Friends, do you see the point?

W. W. MCKEE, 50-48.

Dyersville, Iowa, May 13, 1885.

WHAT TO DO WHEN BEES GET A NOTION OF CLUSTERING ON TALL TREES.

My place is surrounded by tall oak-trees, and bees seem to have a mania for settling in the utmost tops of them when swarming, notwithstanding there are plenty of bushes all around whereon they might settle. This causes me to lose every year the greater part of my swarms. Now, I think I have read somewhere of some device to be placed in front of the hive when the swarm issues, by which the whole swarm can be caught up. If there is such a thing as a successful swarm-catcher in use, I wish you would advise me of it. State price, and say whether it can be sent by mail.

Atlees Sta., Va., May 9, 1887.

D. A. KUYK.

The Alley drone-trap, shown on page 5 of our catalogue, will cause the swarm to return shortly to the hive. If, then, the trap be detached from the entrance, and be placed among the flying bees, the latter will soon cluster about their queen in the trap, and the swarm may be hived. On page 258 of the A B C of Bee Culture an automatic device is described for catching swarms while in the air. I think, however, if the bees trouble you very much about clustering on the tops of tall trees I would clip the wings of all the queens. When a swarm issues, catch the clipped queen at the entrance, cage her, fasten her cage upon a pole (to which is attached a leafy bough), and hold her majesty among the flying bees before they cluster on the highest limb of the trees. In a word, friend K., I would do all I could to discourage the bees from clustering at all by the methods I have given.

HOW MUCH COMB HONEY TO THE GALLON?—MAKING BEES GO TO WORK.

I have sold 350 lbs. of comb honey, each customer asking me to bring a stone jar that will hold 50 lbs. What size of jar must I get to hold 50 lbs. in the comb? As you well know, the jar never holds what it is marked. What does honey weigh to the gallon when in the comb, well filled, capped over nicely?

How much to the gallon when extracted? I am trying to start in the bee-business, but my bees will not swarm, which bothers me very much, as bees are what I am after. I do not understand artificial swarming enough, or know enough of it to try. If my bees lie out on the outside of the hive, please tell me the cause of it, and what to do. J. O. BARNES.

Hickman, Fulton Co., Ky., May 16, 1887.

It is commonly considered that there is about 11 lbs. of extracted honey to the gallon. If the honey is very thick, 12 lbs. should be allowed. About an ounce of comb will hold a pound of honey, so that it would generally take about 12 lbs. of comb honey to make a gallon. A crock to hold 50 lbs. of honey in the comb should then have a capacity of something over 4 gallons. — In regard to preventing the bees from clustering outside, give them plenty of room inside. If bees act lazy, and disinclined to work, right in the height of the honey season, I would contract the brood-nest, but give them an abundance of room in the surplus apartment. I would refer you to the heading of "Comb Honey," in the A B C book, for further particulars about starting bees to work. You say that your bees will not swarm, and you seem to think this an undesirable trait. The veterans would be very glad indeed if they could prevent bees from swarming. If you have a strain of non-swarming bees, friend B., you do not need to be at all alarmed. What you want to do is to make them go to work.

THE NAMELESS BEE-DISEASE, AGAIN.

What is the matter with the bees? In some colonies the main force of the working class seems to be engaged from about 10 o'clock in the morning until about four in the afternoon in driving out and killing a small bee about a size between a house-fly and a common black bee. These bees are very black, except occasionally one with a little mark of Italian. This trouble is confined entirely to the hybrids, so far as I have discovered yet. One colony will soon be ruined. That one I have examined closely, and I find these little intruders hatching. There seems to be about every fiftieth bee that has just emerged from the cell of that stripe. I took 25 box hives last fall to transfer, and keep for five years. They were all blacks, and of a very low grade of hybrids, and this trouble seems to be confined alone to the hybrids. I transferred them this spring, and never discovered any thing wrong until about two weeks ago. D. B. BRYAN.

Desota, Ga.

Friend B., your bees have the disease described under the above head in our A B C book. It is a little discouraging, that no one has as yet been able to suggest the origin. The remedy is to give each hive thus affected a new queen from a healthy colony, then your bees will be all right again. I think it is only by accident that you find it among the hybrids only. It usually affects all kinds of bees alike. I have sometimes seen small black bees hatch out as a result of letting the brood get partially chilled while transferring. Your concluding sentence suggests that this may possibly be the trouble in your case, and not the nameless bee-disease, which it very much resembles, from your description.

FRIEND TERRY'S ADVICE IN REGARD TO POTATO-BEETLES—SEE P. 408.

You see you are ahead of every one else, and have got to take all the beetles from all the neighborhood. I think you will find picking an endless job. I once planted very early and got into about the same fix. I had to use poison. We delayed planting a little this year, partly because we did not want to get ahead of our neighbors and take all their beetles. If all potatoes come up at once, we get only our share. I think you will find poisoning the cheaper way.

T. B. TERRY.

Hudson, O., May 14, 1887.

But, friend T., we are ahead, and we did not use poison either, although it might have been easier. I took Blue Eyes, Cad-die, and Huber, and one of the neighbor's children, down into the potato-patch; and while the children took one row apiece I took two rows, Huber carrying the tin cup for me to drop the bugs in. We went through the whole patch in about an hour and a half. I paid the children 5 cts. an hour, or 5 cts. a hundred for the beetles, as they might choose. Blue Eyes and her schoolmate got 200 during the hour. I did not count mine, but there was a big lot, I tell you. The next day one of our hands followed them up again, getting every bug, and picking every leaf that had eggs on it; and now the patch is pretty well cleared. It cost some money; but if it is as you state it, haven't I benefited the neighborhood by making such thorough work of the first crop of bugs? I know you get less bugs; but while you get 40 cts. a bushel for your potatoes, I get 40 cts. a peck or more for mine.—It is now May 20, and those potatoes are the greater part of them, budded ready to blossom, and I tell you they are handsome.

BEES CRAZY FOR WHISKY.

Do bees need whisky? As our well water is so much impregnated with minerals as to render it unfit for domestic use, I have to haul water from a spring about one-half mile distant. As my old barrel was almost dilapidated, I purchased one of a saloon-keeper (the only thing which I think is worth buying of a saloon-keeper). As the barrel for some time retained a sufficient quantity of whisky to impregnate the water with its offensive taste and smell, the bees seemed almost crazy after it. As long as they could gain access to the whisky-water they would not notice pure water, though it was placed all around them. I have heard of box-hive bee-keepers putting whisky in hives to keep swarms from absconding when hived, but I do not know whether whisky is any benefit to bees or not. I abhor it too much to try it for any thing. I never drank more than a quart in my life.

QUEEN-CELLS NOT HATCHING.

Can any one tell me why queen-cells will not hatch? I have had no less than 40 fine cells reared under the swarming impulse, and have had only one cell hatch. I had a great many cells last season that failed to hatch. I do not know the cause. The queen larva begins to dry up or decay before it comes to maturity. There is generally a great quantity of royal jelly in the bottom of the cells. Not much surplus honey yet, but bees are unusually strong at this date. It is getting too dry for bees to do much. We have had only one shower in 53

days. I never saw it so dry here at this season of year since I have been here, about 20 years. I have not seen many reports from Texas in two seasons. What is the matter? Are bee-keepers too busy in gathering and selling their honey, and counting their money, to write, or are they all in Blasted Hopes?

G. W. BEARD.

Milano, Texas, May 2, 1887.

Friend B., I am inclined to think the trouble with your queen-cells is only a transient one. We have sometimes had a lot of cells that seemed to act as you state; but they hatched out all right soon after, and you have probably had the same experience by this time.—We are very sorry to hear that the dry weather is commencing again this season in Texas.

NOTES AND QUERIES.

A HIBERNATING BUMBLE-BEE.

Q N p. 302 friend Doolittle asks where and in what state bumble-bees pass the winter. While digging a hole in the ground, about the 1st of April, 1879, when at a depth of 18 inches I threw out a bumble-bee which soon came to life. There was nothing, apparently, for her to eat, so with friend Clarke I say it must have been hibernation.

F. D. CULVER.

Quincy, Mich., May 11, 1887.

[To be sure, it was hibernation, friend C., and the real genuine hibernation too; but if you will bury up some honey-bees—queens, drones, and workers—and have them come to life in the same way, we will pay you \$100 cash. You must, however, bury them on our premises, and dig them out in our presence.]

WHAT TO DO WITH A SWARM THAT HAS REDUCED ITSELF.

Please tell me what to do when a colony of bees is about to go to nothing, after swarming. It has swarmed three times this year—April 6th, 12th, and 14th.

J. B. FOLLETT.

Divine, Tenn., May 7, 1887.

[You have nothing to do, friend F., but to see that they have a queen. Don't you need the A B C book?]

CARNIOLANS VERSUS ITALIANS.

I wish to learn something about the Carniolans and albino bees. What points of superiority are claimed for them over the Italians? Do you consider them as good or better than the Italians?

Trempeleau, Wis.

W. M. ALLEN.

[We did not consider the Carniolans, after testing one colony one season, as good as the Italians—see p. 551 for 1886. However, some of our good friends do not agree with us.]

WAS IT FOUL BROOD?

I had every symptom of foul brood, such as has been described in your journal; but I stopped it before it advanced to a virulent form, by simply removing the queen and introducing a young one. In about 17 days after, the young queen had all dead brood removed, and not one of the cappings of brood was perforated. All looked healthy and clean.

GEORGE STRANGWAYS.

Elora, Ont., Canada.

[Some of our foreign friends claim that the removal of the queen will sometimes cure foul brood. But we feel pretty sure it would not have cured ours.]

turns the edges of the burlap up all round, and makes it tight all round. I then fill the crate full of chaff, and put on the $\frac{1}{2}$ -story cover, and all is done. I did not look at my bees until May 2d. I found them all right. Queens were all alive, combs bright, and lots of brood. I find the crates *better* than any cushion, as I can lift off the cover any time without disturbing the bees. J. EASTMAN.

Fallsington, Bucks Co., Pa., May 9, 1887.

REPORTS DISCOURAGING.

WINTER LOSS.

YOU ask for "reports discouraging." I went into winter with 18 colonies, all in Simplicity chaff hives. I now have 11 left—2 good colonies, the rest very weak. The best colony is Carniolan, a daughter from an imported queen from Frank Benton. Why they dwindled down this spring I can not explain. I lost some in the latter part of February, as the first two weeks of February was warm. The bees began to raise brood very fast, using all the honey in brood-nest, then there came two weeks of steady cold weather, and the bees starved with plenty of honey just out of their reach. The others dwindled away too quick, with brood and honey, but no old bees to nurse them.

SAMUEL HEATH.

Rimer, Armstrong Co., Pa., May 7, 1887.

UNFAVORABLE TO MRS. COTTON.

I am trying as hard as I can to make a success in keeping bees. I have tried twice, and have failed under the way Mrs. Lizzie Cotton manages bees, and I have also lost money by her by following her plans. I am now managing bees under your plans, and things are looking more favorable. I use your hives, and am a reader of the A B C book.

S. Woodbury, Vt., Apr. 13, 1887. W. F. ANGELL.

OTHER WINTER LOSSES.

I see that you want more reports discouraging. If all who have had bad luck in this part of the State would send in their reports it would fill GLEANINGS half full. Last season was wet and cold here; but little clover honey, considerable milkweed honey. Some have spoken of it as beautiful golden honey. I consider it the poorest honey I ever saw, and to that and pollen I attribute the great loss the past winter. I don't think that the winter was severe. Louse nectar, as spoken of by Geo. Wright, I know nothing about. My bees gathered but little if any thing late in the fall. At the close of the swarming season I had 34 swarms. I took about 600 lbs. of comb honey, most of it the miserable stuff spoken of. I use Vandervort's chaff hive. The 34 swarms were well packed in chaff; and with what honey they had in the brood-frames there was enough and to spare. The poor quality of the honey, and too much pollen (not the winter), reduced them to 15, and then from rather weak to very weak. I do not think the cellar is made in which they would have wintered on such stores.

S. B. SAFFORD.

Amasa, Pa., May 7, 1887.

IS IT FOUL BROOD?

I am not dead myself, but my Italian bees are dead—all died last summer with foul brood. It's the fourth attempt I have made to get a start with Ital-

ians. I can not account for it. None of the native bees had it, and I did not know what foul brood was till I got some Italian bees. I had thought I would write you about it ere this, but neglected to do so. I have 20 hives in good condition. J. J. KEITH.

Louisville, Ga., Feb. 25, 1887.

I can scarcely conceive how your Italians could have foul brood, and not your black bees. It is commonly considered that the disease is no respecter of persons—at least a bee personage. If it is a fact that you have foul brood, I should suppose that you had just purchased your Italians of some one who already had the disease in his apiary, and when the Italians were shipped you they brought the disease with them. One thing, however, is certain: If you have the real virulent foul brood it will attack the brood of black bees just as quickly as it will the brood of Italian bees. If you do not think so, try it once. If, upon trial, it does not have any effect upon the black bees, then you certainly have not foul brood.

BLASTED HOPES.

LOCALITY OVERSTOCKED, AND NO MARKET FOR HONEY.

I HAVE wintered 136 colonies of bees out of 162. Those lost were nearly all nuclei. Bees have wintered well here. This locality is overstocked with bees. I believe there are 2000 colonies within six miles of this place. But the worst part is, a good friend has purchased property here and located an apiary of nearly 100 colonies just eight rods from my apiary. Last season our bees when swarming would very often get together and cluster together. Sometimes we would not see them swarm, and find them after they had clustered; then we could not tell whose they were, but we are good friends all the same.

There is no sale for honey here. Markets are overstocked. One of our merchants told me a few days ago that they had about 1000 lbs. of honey, for which they would take 6 cts. per lb. They paid 10 cts. The outlook is gloomy. I should like to sell out. I am discouraged. Put me in Blasted Hopes. Nappanee, Ind. I. R. GOOD.

Why, friend G., I do not believe the matter is so very bad, after all; and as you have generally done pretty well with your bees I don't believe I would think of trying some other calling. Other industries have their times of depression as well as ours.

75 PER CENT OF THE BEES DEAD.

As I am a young subscriber to GLEANINGS, and see there "Reports Encouraging," I must join the "Blasted Hopes" column. Schoharie County is an excellent place for bees in summer. Last season was very poor, and the past winter memorable for losses. Perhaps 75 per cent of the bees are dead. I had 15 last fall, and shall have but 6 left. I know of one old veteran in the business, who, out of about 80 colonies, lost all but four, which he sold, including his old hives, for \$8.00. A very few may not have lost more than a third. A man told me that he had 14, and lost every one.

J. VAN WAGENEN, JR.

Lawyersville, N. Y., May 7, 1887.

MYSELF AND MY NEIGHBORS.

They that turn many to righteousness shall shine as the stars for ever and ever.—DAN. 12:3.

OF course, you have noticed, dear reader, how bright and happy you feel after having encouraged some fellow-being in the ways of righteousness; and I suppose you know, too, how dismal and dull one feels when he has hesitated or neglected an opportunity of speaking a word for righteousness. Well, when I left those boys in that hotel in Michigan and went into another room without saying a word to them, I had just that sort of feeling—I felt blue and dull; I was in a sort of spiritual darkness. Even the precious promises of the Bible seemed to be dim and obscure. There was a kind of feeling that wickedness was going to keep on, and, may be, ultimately prevail, and that there was not very much use in trying to do any thing about it any way. Well, did you ever feel that such thoughts are wicked? I know they are wicked—they are Satan's promptings. But whenever you sit still and let things go on from bad to worse, without making a movement or opening your mouth by way of protest, you will be sure to feel this spiritual darkness; and doubt and want of faith in regard to God's promises, and dim perceptions of spiritual truths, seem to be the consequence. I made up my mind that I would do better when another such opportunity should offer.

I reached Owosso promptly; but Prof. Cook was watching at one depot, and I came in at another, as I have explained to you. As soon as I learned that the two depots were one-fourth mile or more distant, I hastened to the one where I was expected. A man informed me that Prof. Cook had just been there, and that he had heard him say that he was looking for somebody who did not come. I inquired in the town for him, but they had not seen him, and finally I ascertained he had gone to his farm.

"Well," said I to myself, "if my plans are frustrated, what plans has the Master for me, under the circumstances?" The only thing for me to do was to go to a livery stable and get somebody to take me out to the farm, about four miles.

Did you ever notice, dear reader, how many people there are in towns and villages sitting around idly? In cold weather they sit down by a stove, and neither move nor speak for hours. I have often wondered how it is possible that people can sit still, doing absolutely nothing at all, when this bright world is open before us, and when such grand and wonderful opportunities spread themselves out before every human being. Why, if I were out of a job I could think of a hundred different things that I should delight in doing at once. I can remember a few times in childhood when I had nothing to do; but since my teens the hours have been very scarce when there was not something I wanted to do very much indeed, just as soon as I could get a spare moment.

Let me digress just enough to tell you

what it is I should like to do just now. There are a great many things that I mean to do this afternoon; but there is one thing that I have for several days been proposing I would do as soon as it gets dark. It is this: About a week ago, in crossing a plank near the carp-pond I heard a sort of ticking or snapping. Perhaps you would not have thought any thing about it, but passed right along. Now, I have learned by experience that dear old Dame Nature has wonderful secrets to unfold; and oftentimes the only hint she gives you is some unusual noise or strange occurrence. I should have supposed the noise was the work of insects; but insects are not very plentiful just yet, and it was down on the side of a bank near the water. Even though somebody was waiting for me, I climbed down; and by listening at different points I decided pretty nearly where the faint sound came from. Sure enough, at the side of the bank where the water trickled out from the carp-pond there was a sort of bubbling in the mud. The bubbles came with great regularity, and their bursting made the ticking or snapping sound. It was gas of some kind, issuing from the earth. It did not take me long to build air-castles in the way of lighting our manufactory and running our machinery by means of natural gas found on our own premises. I am sorry to say, however, that, when tested by a lighted match, when I had more leisure, it did not prove to be the illuminating gas that has made such a stir in different parts of Ohio. Nevertheless, I enjoyed my discovery, and I am not through with it yet. Now, then, how *can* people sit still when there is so much to be seen, so much to be discovered, so much to be studied out, so many wonderful things of interest all round about us? When I started for the livery stable I wondered if livery stables were pretty much the same thing the world over. I am afraid they are the same, dear reader. By the stove sat a boy, and he was a fair type of many of the boys in America. He was not doing a thing while he sat by the stove. I am not sure that he even looked up when I came in. In answer to my inquiries, he replied briefly. A few minutes later the proprietor called this boy by name and directed him to drive me to Prof. Cook's farm. Although it was near the first of April, it was a wintry day, except that every thing was bright with a flood of sunshine. For some time we rode together in silence. What should a boy in his teens have to do any way, with a man toward fifty? What ideas could they be expected to have in common? Unless I made an effort our whole journey would be one of silence on both sides. Satan whispered, "This boy has no intelligence, and he probably is not even thinking at all. There is not any use in wasting your breath in trying to wake him up out of his characteristic stolid indifference to the world in general." Another voice said, "Christ died for him, whoever he is. You behaved in a cowardly way but a few hours ago, and you resolved to do better next time. Now, then, old fellow, if you really do love God and humanity, show your faith by your works."

I spoke to him in regard to different things; but he replied by yes or no, without even looking at me. When I was in the jewelry business I always prided myself on my ability to sell goods. If I wanted to sell a man a watch, the first thing was, in ordinary cases, to get acquainted with him and make myself agreeable. When people became acquainted with me they usually were willing to trust my statements. What I said would have but little weight until I had made myself agreeable and pleasant. It is a trade to sell watches; it is a trade to sell goods of any kind, and an expert salesman usually commands a large salary. It occurred to me that I should have to use much the same energy in getting acquainted with this boy that I used to in selling goods. Finally I turned to him, determined to see whether I could break the shell of indifference or bashfulness (was it the latter?). I asked him his name. He replied, briefly, "Henry." Then I turned myself toward him and commenced something like this:

"Henry, we are going to ride perhaps an hour together, and I want to get acquainted with you. I wanted to know your first name because I want to talk with you as if we had been friends a long while; and I can't talk with anybody easily unless I call them by their familiar name as other people do. Perhaps you would like to know why I wanted to get acquainted with you at all. Well, Henry, it is because I love all the boys. I want to see them grow up to be good men; and, most of all, I want them to become Christians."

At this he looked me full in the face in some astonishment; but when he fully understood that it was in regard to his soul's salvation that I intended to speak, you should have seen the transformation that came into that boy's face. I had not seen him smile before at all; but now a faint smile lighted up his boyish features. But that smile was worth every thing to me. There was in it a look of innocent wonder such as a baby shows in its first smile of recognition. Now he was willing to talk. I asked him about his father and mother. The mother was a Christian, and it was the old, old story. He had been in the habit of going to Sunday-school; but for a year past, or more, he had decided he was getting to be too old. I wonder if Henry will forgive me if I tell how he passed his Sundays. With boyish frankness he admitted he had learned to swear just a little; he had also commenced to smoke cigars just a little; and he knew how to play cards just a little. He knew about other things too, just a little, that I need not tell of here. I presume his mother did not suspect what he frankly confessed to me. I asked him what he thought about the Bible and Jesus, and a future after this life is past. He was not thinking very much about them nowadays; in fact, these other things had driven them out of his head. He had heard men speak sneeringly about such things, and he was fast learning to do so himself. Well, I worked hard during that hour.* I plead with Hen-

ry; I held up before him the future if he kept on in the downward road; then I told him, on the other hand, of God's love and of his promises. I told him of our little band of Christian workers in Medina—of our prayer-meetings; I told him of the boys I had met in jail, and I spoke of the habits that had brought them to prison. He was deeply interested in all this, and I was surprised that I could interest a boy in his teens if I tried hard. He asked me many questions, and I told him as much as I could about the great world, with its opportunities that lie before him. When we were ready to separate I felt that Henry was my friend, and I *knew* that I was his friend. I told him I might never see him again, but that I should think of him often and pray for him.

"Henry, does your employer give you any rules in regard to money you receive from strangers? What I mean, is it yours, independent of your wages, even if you tell him about it?"

He replied that it was.

"Well, Henry, here is twenty-five cents, which you are to use just as you please, only use it for some good purpose. Buy something with it to remember me by, if you choose; and please don't forget the promise you have given me, to go back to Sunday-school; to stick closely to your mother, and follow her advice. Try hard to talk to her as you have talked to me here to-day. Don't keep back any thing; and, above all things, my boy, don't forget Jesus who died for us all. Don't ever again let his dear name pass your lips in vain. Don't go with bad boys; don't stay where you hear bad talk; and may I hope to hear some time that you are not only a good man, but a good *Christian* man."

Now, dear reader, how do you suppose I felt as I took his childish hand in mine and bade him good-by? I hardly need tell you that the darkness and clouds of the morning were gone. My faith was as bright and clear in the Savior's love and the Savior's promise as is the clear blue sky after a summer shower. And I was happy too. A peace filled my heart that comes from no other service or work. It was the peace that Christ Jesus and he only can give. Why, the memory of that forenoon's work was as a sweet perfume pervading my whole being, even when I was thinking of something else. Over and over again I would forget myself and be wondering what it was I was so glad and happy about. It made my whole visit pleasant; it made me love everybody—even the sinful and wicked. And do you not see now that it was nothing more nor less than the fulfillment of the little text at the head of this talk? You may verify it in your own experience, for you probably have just such neighbors right around you. May God help us to remember the boys! May he help us to remember, too,

this case I was working unselfishly. In fact, I had no thought of any pay in any shape whatever. It was simply for *Christ's* sake; and without being aware of it I was standing where the promise reached me when Jesus said, "Inasmuch as ye have done it unto one of the least of these my brethren, ye have done it unto me."

*Yes, I had worked as hard and earnestly as I used to work in selling a high-priced watch; but in

that a little earnest work may be the means of stopping some of these little ones from that which may end in shame and disgrace and ruin.

They that turn many to righteousness shall shine as the stars for ever and ever.—DAN. 12:3.

TOBACCO COLUMN.

SOMETHING MORE FROM FRIEND STOKELY.

OUR friends will recognize friend S. as the bee-keeper who had lost his wife (see Our Homes for March 15).

Friend Root:—I have just finished reading the Tobacco Column in GLEANINGS for April 15, and the idea of giving you my experience occurred to me. Some time in the autumn of 1843, at which time I was 13 years of age, I commenced upon a very small chew; but, I am proud to say, I never finished it. Before we returned any of our jewels to the Master, we numbered nine—the youngest member being now 10 years old, and that little chew covers the extent of our indulgence in the habit, and a few dimes' worth given to a good old mother, is about the extent of our expenditures for tobacco.

Your zeal for the elevation of the human family is laudable in the highest degree, and we trust that it will find appreciative hearts. G. C. STOKELY.

Arnoldville, Ind. Ter., Apr. 27, 1887.

I am very glad to hear of this, friend S., and we are all glad to know that you are really among those who are seeking the kingdom of God and his righteousness. And so there are several of you to mourn the loss you told us about before. We are very glad indeed to find you are on the right side of the tobacco question. If the youngest is 10, it is hardly likely that any of you will take to tobacco in the future.

I have quit the use of tobacco; and if I begin again, I will pay the price of the smoker.

Planter, Ga., Apr. 10, 1887. T. M. O'KELLY.

I promise to quit the use of tobacco in any form; and, if I resume its use, I will pay for the smoker sent me.

E. J. GOULD.

Lawrence, Kan., April 26, 1887.

My brother has quit the use of tobacco; and if you think he is entitled to a smoker, send one to him, and if he commences to use tobacco again I will pay for the smoker.

S. E. SIMENS.

Upland, Grant Co., Ind., Apr. 26, 1887.

John Trego, the man you sent a smoker to for quitting tobacco, requests you to send one to James Wells, at Filley, Cedar Co., Mo. Mr. Wells promises to quit tobacco or pay for the smoker.

Virgil City, Mo., Apr. 21, 1887. E. LISTON.

A friend of mine wants to quit using tobacco, and he says he will pledge himself to quit if you will send him a smoker. He will pay you for it if he does not quit. His name is T. K. Roberts.

Boyce, La., Apr. 12, 1887. T. G. MORGAN.

Will you please send a smoker to Theodore Freeman, Tioga, Pa., who has given up using tobacco, and promises never to use it again? Should he break his pledge I will remit for smoker.

MRS. W. E. NICELY.

Mitchell Creek, Pa., May 1, 1887.

OUR OWN APIARY.

CONDUCTED BY ERNEST R. ROOT.

FOUL BROOD—OUR OLD FRIEND THE ENEMY, AGAIN.

I AM sorry to be obliged to give a sub-head like the above. I had determined that I would not again bring up this disagreeable subject of foul brood; but in justice to our readers and patrons, I must tell the facts. In the last issue, in this department I reported no foul brood, and I believe I rather conveyed the idea that we thought we had entirely eradicated the disease; but just about the time that GLEANINGS had reached our readers, bringing this intelligence, foul brood broke out. I was just passing down the central apiary when one of our young men who was examining a colony called out, "What do you call this?" I nervously examined the comb, and with a toothpick I poked into two or three cells, which my eyes told me too plainly contained foul brood. On drawing out the toothpick, the same ropy, sticky, stringy matter adhered to the end. The disease, however, was then in only its incipient stage, and probably a day or so before would not have been apparent. I now said to the boys, "We shall be almost sure to find other cases adjacent to this one." A little later in the day, when flying bees had dispersed, I threw off my coat, and, with smoker in hand, proceeded to investigate. I singled out first the hive that had its entrance opening in the same direction, and in other respects similarly situated. On opening it I was not surprised to find that it was diseased. I shall again refer to this point further on. We soon discovered two or three more diseased colonies, and, in the course of a week, twelve or fifteen cases of veritable foul brood were found.

Now, the question that will naturally arise in the minds of many of you will be, How was it, that, for six weeks, with no foul brood, the disease should break out so suddenly, and almost simultaneously? The answer is this: I had previously instructed the boys to allow the colonies to reduce their stores almost to the starvation point; that is, I desired to have the bees consume all the stores left over from last season. If said stores contained any diseased matter, they would soon reveal their true condition. It seems that the bees at the time foul brood broke out had reached the very bottom of the cells, where, evidently, some of the honey was still diseased from last year, but which, during the six weeks of no foul brood, had been covered up by the few stores the bees were gathering from fruit-bloom and other sources.

I know that some of the readers will condemn us for being so sure that we had cured foul brood; but it seemed to us then that six weeks of healthy brood, and the colonies nearly on the point of starvation, and still no evidences of foul brood, we had really conquered our old enemy. We are reminded strongly of this fact: That, during the height of brood-rearing, foul brood, where an apiary has been diseased previously, may

disappear for a period of as long as six weeks, possibly longer, and yet reappear. We are reminded, also, that foul brood is a subtle enemy. He will hide himself away, and then when you have just drawn a breath of relief, thinking that you have conquered him, he will rise up with renewed strength, and let you know, if you never did before, that he is almost one of the invincibles.

In last issue, we had decided to fill orders from the home apiary. We had not, however, sent out more than two or three before the condition of the apiary was discovered, so that the friends who may have purchased of us do not, I think, need to be alarmed; for, as we have repeatedly stated, foul brood can not be communicated by shipping bees and queens by the pound.

As soon as we became aware that foul brood had reappeared, we immediately decided to reinforce the Swamp Apiary. On the supposition that we had cured foul brood in the home apiary, the former had been abandoned. Word was immediately sent to friends Rice and Shook, located some twelve miles south of us, to bring us a couple more loads of bees, in order that we might continue filling orders as heretofore, but with bees which *we knew to be entirely free* from any traces of the disease. In response to the order sent, early yesterday morning (May 24th) they arrived with the bees. We then drove over to the Swamp Apiary, and in the course of the day you might have seen 57 colonies scattered here and there among the blackberry-bushes and young beech-trees. In the evening of the same day, orders for bees and queens then on our books were filled, without causing a delay of more than one or two days.

To me, the location of this new apiary is rather pretty. There is quite a growth of underbrush, long grasses, and weeds. The wild and uncared-for appearance of the place is peculiarly attractive; and the shrubbery, together with small trees, will give the bees sufficient landmarks by which they can easily locate their own entrances.

In this connection I wish to make mention of the chief factor which I think spread foul brood in the home apiary. In the latter place, the readers of the ABC book, and those who have seen the picture of the apiary, will remember that the hives are arranged with geometrical accuracy. The grapevine trellises and general surroundings of each hive are almost identical in appearance—so much so that the bees of the several hives are very frequently confounded as to their real entrance. On almost any bright day in early spring, when the bees are out, we find scores and scores of them buzzing around at the back side of some hive, having mistaken it for their own hive. This general symmetry in the arrangement of hives causes the bees to become mixed, to a very great extent. Now, then, if one colony is diseased, almost all the neighboring hives will be pretty sure to have the disease sooner or later, because the young bees from the diseased colony, not being able to distinctly locate their own hive, will enter other hives, the entrances to which have almost

the same appearance. In this way the infection is carried. In the Swamp Apiary we decided to abandon all rules of symmetry—make the entrances and the general surroundings of each hive peculiar to itself. We did not do this because we feared foul brood in the Swamp Apiary, but because young queens, if the entrances of different hives are alike, are quite apt to get into the wrong hive and so be killed. I am well aware, that an apiary which has a symmetrical appearance looks nicer, and has a more pleasing look to the eye, but I have felt confident for some time that we ought to have sufficient distinguishing features about each hive and its location, so that the bees will not be continually getting into the wrong hive, and so waste valuable time, in the height of the honey-flow, in trying to determine where they belong.

THE BINGHAM SMOKER.

Some three or four months ago, at my request Mr. T. F. Bingham sent me one of his "Doctor" smokers. At first I did not like it. I followed the directions which accompanied the smoker—that is, to use sound hard wood for fuel. For some reason or other I could not make it work. That kind of fuel was hard to light; and when I succeeded it had a fashion of going out. I next tried sawdust fuel. The latter material was so combustible that the Bingham sent a tongue of flame out of the nozzle for a distance of three or four inches, along with a goodly number of sparks. Some of the sparks lodged in my clothing, and a few in my face until I actually became afraid of the thing. After several unsuccessful attempts I laid the smoker on a shelf in the house apiary, and it remained there for a couple of months. One day I concluded I would give the thing a most thorough trial. I knew that good bee-keepers had used it and liked it, and so instead of using hard wood I determined to try Dr. Miller's plan; *i. e.*, fill the fire-box with planer shavings, and stuffing the nozzle with green grass. As the Bingham seemed inclined to send out a volley of sparks when shavings or other light fuel was used, I thought that the idea of stuffing the nozzle with green grass seemed reasonable. I accordingly grabbed up a handful of Excelsior, mixed with fine sawdust, lighted it, and shoved it down the barrel. I then crammed in more Excelsior, packing it down tightly. Into the nozzle of the smoker I crammed a handful of green grass, and adjusted it on to the barrel. The results were highly satisfactory. I used the smoker from three o'clock until seven in the evening while I watched for foul brood. I had a good volume of smoke, but not a single spark. I have since used it, and will now say, even at the risk of hurting our trade in the Clark smoker, that the Bingham is a first-class implement. The valve works quickly, and a slight compression of the bellows will send a very gentle whiff of smoke. It is always the same, as there is nothing in its construction to become clogged up with soot. But without the green grass in the nozzle, I certainly could not tolerate the sparks. The grass not only arrests sparks, but prevents too great a draft for the shav-

ings, which otherwise would be ignited into flame, and shoot out at the nozzle. Friend Bingham, why don't you recommend shavings and green grass, instead of hard wood? But possibly I haven't caught the knack of making it burn. May I venture to suggest, that *you* haven't learned how to use shavings and grass?

In favor of the Clark, I must say that it will send a stream of smoke to a greater distance than the Bingham. It will fill easier, and light more quickly; but it has not the lasting qualities of the Bingham. At present we are working to remedy some of the defects in the Clark.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER,
MEDINA, OHIO.

TERMS: \$1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, JUNE 1, 1887.

He which converteth the sinner from the error of his way shall save a soul from death, and shall hide a multitude of sins.—JAMES 5: 20.

GLEANINGS now has 7314 subscribers—more than it ever had at any other time in its history.

THE "KENTON BEE-HIVE."

THE above is the title of a monthly bee-journal, just started at Kenton, O. The editors are Smith & Smith, whose names our readers will doubtless remember having seen very frequently in our advertising columns. The first number has 12 pages, and can be obtained by corresponding with the editors, Kenton, O. Price 50 cents a year.

THE NEW JAPANESE BUCKWHEAT.

THE demand for this new buckwheat has been enormous; but by repeated purchases we are still able to furnish it at prices given in our issue for April 1; viz., \$1.75 per peck; half-peck, \$1.00; 1 lb., 25 cts.; $\frac{1}{4}$ lb., 8 cts. If wanted by mail, add 5 cts. per $\frac{1}{4}$ lb., or 18 cts. per whole pound, bag and postage. We mention it again, because it is now approaching the time to sow it, in most localities. We think no bee-keeper can afford to neglect giving it a test. A quarter-pound package will give you quite a start for next year, if you don't care to go into it any further. For a picture and full description of the plant, see page 167, March 1, 1887.

FULL COLONIES AND NUCLEI OF ITALIAN BEES AT GREATLY REDUCED PRICES—A SPECIAL LOT.

FOR certain reasons, it is desirable to dispose of at once 40 colonies of Italian bees and about 100 nuclei in the possession of Mr. G. A. Beach, of Quitman, Nodaway Co., Mo. These bees are in Simplicity frames, are guaranteed to be good Italians, and there has never been any foul brood within 200 miles. Until they are closed out, we will make the very low price of \$5.00 for a full colony, or \$2.00 for a

two-frame nucleus, or 50 cents less with hybrid queens. Further particulars can be obtained by writing to Friend Beach, as above. Remember, these prices are given only on bees to be shipped from Missouri, and you must state at the time of ordering that you wish to take advantage of this offer. Full colonies are ready to be shipped at once, and nuclei any time after June 15. Send orders and money to us.

VARIOUSLY MARKED HYBRIDS.

A SUBSCRIBER sends us a cage of bees which he says are from an untested queen. Some of the bees are nicely marked Italians, and some of them are almost black, while others have two yellow bands. The queen, of course, proved to be hybrid. Our correspondent wished to know how this can be, as the bees in question are all from one queen. In private correspondence we have explained this several times; but for the benefit of beginners we will say it is not uncommon, when bees are hybrids, that variously marked bees will be found, all the way from pure Italians to pure blacks. We would refer our correspondent and others to the article on "Hybrids," page 123 of the ABC book, where the question is fully discussed.

COMPLICATED SURPLUS HONEY ARRANGEMENT.

EVERY few days some one sends us a surplus arrangement which he has invented, and about which he desires our opinion. In general, we can say they have been sent in by those who have had but little experience with bees, and as a rule they are altogether too complicated for practical use. One came to-day, marked on the side, "Patent applied for." We should say it would *cost* to produce honey on a large scale, with this sort of arrangement, fully what honey will sell for at the present quotations. We should remember that the idea nowadays is to construct surplus arrangements which will produce honey at a minimum cost. The simplest device that can be gotten up, consistent with the objects sought and habits of the bees, is the one destined to produce honey at the lowest possible cost. The surplus arrangement referred to above has separators, which we should say would cost two or three cents apiece to make. Then there are wedges, several sizes of sections, besides other complications, which would make the case altogether too expensive for the average honey-producer. The ideas sought after by the inventor are good, and his invention ingenious; but we hope our friends will try to remember that we don't want a surplus arrangement which can be adapted to every hive, invertible or non-invertible, contractible or non-contractible—in short, one which will do almost any thing any bee-keeper ever suggested. A patent medicine which will cure all diseases known under the sun is worthless; and I think we can say, for the same reason, that surplus comb-honey arrangements which will accomplish every thing ever dreamed of are likewise worthless. As a rule, our largest and most successful honey-producers are using very simple arrangements.

FOUL BROOD IN WINTER.

A CORRESPONDENT writes us that his bees died of foul brood during the last winter, and he is located in the Northern States. Of course, this would be impossible. Foul brood always disappears for the season at the approach of winter, or, at least, when bees cease rearing brood. Our correspondent

should remember that foul brood does not in any manner affect the *bees*, but it is wholly a disease of the *brood*. When brood-rearing ceases, of course there is nothing for the malady to work on. For the same reason, removing the queen removes the disease as soon as the brood is all hatched; and it can not commence again until more brood is started. The bees referred to above probably died from causes usually ascribed to wintering.

"OUR LITTLE NEIGHBORS."

We are pleased to inform our readers that the Rev. John Dooly, 395 Broome St., New York, has been giving a lecture, entitled as above. Friend D. has sent us an admission ticket, and on the back of it we find it reads as follows:

OUR LITTLE NEIGHBORS.

Who they are; the houses they live in; the way they live; what they gossip about; their love; their hatred; their riches—how they gain and lose them.

N. B.—Some of "our little neighbors" are invited to be present. If they do not come, THEIR EARS WILL BURN; if they come, they may make OUR EARS BURN.

Friend D. is an evangelist. He is and has been holding services nearly every day in the week, in the great metropolis of America, as above stated. He takes up the subject of bee-keeping simply as a recreation from his arduous duties. We sincerely hope that he may find in bees sufficient rest to help him in his glorious work.

"TRADE SECRETS."

THE above is the title of a new work just out, written by John Phin, of the Industrial Publication Co., 15 Day St., New York. It contains a large amount of valuable information that can not be readily found elsewhere. It gives not only formulae for manufacturing an immense variety of articles, but important and trustworthy hints. In the introduction there is information, full of interesting incidents, explaining the whys and wherefores. The book is arranged in the convenient form of an encyclopedia, and each recipe can be found in its alphabetical place. We will take a case in point. Under the head of "Microscopes" the author gives a very simple plan for making a simple lens, and one, too, that has considerable power. On page 67 the author says, in speaking of one of the little microscopes which he made, "We have one now before us by which we can easily see corpuscles, or globules, as they are sometimes called, of human blood, and we can readily see the difference between the blood of a man and that of a frog. We can also see clearly the construction of the *sting* of a bee and the eye of a fly." John Phin is well known as a skilled microscopist, and we feel sure that, when he makes the foregoing statements, he knows what he is talking about. These microscopes can be made for a very small amount of money, and we have no doubt that an enthusiast on the subject of microscopes could, with a small outlay, make just such a microscope as there described. Under the head of "Honey" we find various recipes for making the artificial product. The author very wisely says, along with the recipes he gives, that pure honey can now be produced so cheaply that it is almost impracticable to adulterate it to any large extent. We have no doubt that the work will be found valuable to many of our tradesmen, and to others who would like to know how some things are made. The price of the book is 60 cts., postpaid, and can be obtained of the publishers as above.

SPECIAL NOTICES.

6-INCH PELHAM MILL FOR SALE.

WE have on hand a new 6-inch Pelham mill that we took in exchange for one of our mills. I believe it does not have the latest improved frame, but it is in first-class condition, and does good work—that is, for a Pelham mill. We will sell it for \$8.00, although the retail price of one of that size is \$9.00. If necessary, we can send you a small sample of its work by mail.

A 15-INCH POWER DRILL FOR SALE.

THE work in our machine-shop has increased to such an extent that we have been obliged to purchase some new and expensive pieces of machinery. Among them is a new power-drill. We now offer for sale our old power drill which we have used for several years. It has a 15-inch swing, an automatic or hand feed, and may be run by power or by hand. It is just the thing for an ordinary blacksmith shop. It cost originally \$75.00; but as the price of iron-working machinery has come down considerably within a year or two past, we will offer this drill at the low price of \$15.00, boxed on the cars at Medina. Any of you who would have use for such a drill will find it is a rare opportunity. Let us hear from you at once.

CIRCULARS RECEIVED.

The following have sent us their price lists:

J. B. Hains, Bedford, Ohio; an advertising sheet of bee-supplies.

J. W. Clark, Clarksburg, Mo.; a 4-page circular of apiarian supplies.

F. W. Holmes, Coopersville, Mich.; a 10-page circular of Dunham and Vandervort foundation, with a few other supplies.

G. W. Bercaw & Bro., Fostoria, O.; a 16-page price list of rubber stamps, especially designed for bee-keepers.

SYRIAN, ITALIAN, AND ALBINO BEES *and* QUEENS.

Untested queen, 75c; tested, \$1.50; bees by the pound, 75c; hybrid queen, when we have them, 50c; frame of brood, 75c. Please don't send stamps.
11-12-13d N. E. COTTRELL, Fayette, O.

Costs less than 2 cents per week.

THE CANADIAN BEE JOURNAL.

THE FIRST DOLLAR WEEKLY IN THE WORLD.

THE D. A. JONES CO., PUBLISHERS, BEETON, ONTARIO, CAN.

D. A. Jones is its editor, and this fact is a guarantee of its worth. It is thoroughly practical and contains weekly excellent articles from leading bee-keepers in the United States and Canada. Fifty-two numbers make a volume of 1040 pages. American currency and stamps at par. Samples free.

QUEENS.

I have them, bred from a best selected queen of Root's importation, 90 cts. each; 6 for \$4.50. I can give all orders immediate attention, and ship by return mail. Send postal for dozen rates.

11tdb B. T. BLEASDALE,
983 Woodland Ave., Cleveland, Ohio.

ITALIAN QUEENS, Untested.....75 cts.
11tdb T. A. PEW, Middletown, Mo. Six for.....\$4.00

Italian Bees

Two-frame nuclei, both frames containing brood, with all adhering bees, and untested queen, from imported mother, \$2.25. Bees, per pound, \$1.00. Untested queen, \$1.00. Safe arrival and satisfaction guaranteed.

Wants or Exchange Department.

Notices will be inserted under this head at one-half our usual rates. All ads. intended for this department must not exceed 5 lines, and you must say you want your ad. in this department, or we will not be responsible for any error. You can have the notice as many lines as you please; but all over five lines will cost you according to our regular rates. Of course, this department is intended only for bona-fide exchanges.

WANTED.—To exchange for good horses and mules, 200 colonies of bees in Simplicity frames; also 40 acres of land adjoining the city.
20tfdb ANTHONY OPP, Helena, Phillips Co., Ark.

EGGS for hatching.—Wyandottes, Polands, Hamburgs, and Leghorns, in exchange for section boxes, or foundation. Circulars free.
4tfdb. A. H. DUFF, Creighton, Ohio.

WANTED.—To exchange Barnes foot-power saws and bees, for steam-engine, honey, or beeswax.
7-12db C. W. & A. H. K. BLOOD, Littleton, Mass.

WANTED.—To exchange 15 Simplicity hives (2-story) half comb and half foundation, all in good condition. Make us an offer.
10-11d J. D. HALSTED, Rye, N. Y.

WYANDOTTE and Houdan eggs or birds in exchange for bee supplies; see adv't in another column. JAMES EVANS, Box 89, Schaghticoke, N. Y.
10tfdb

WANTED.—To exchange a second-hand Hall typewriter for extractor, Italian bees, or bee-keepers' supplies. E. P. WEBSTER, Gambier, O. 11d

WANTED.—To exchange three city building lots, 25 x 102, in the city of St. Andrews Bay, Florida, for Italian bees, comb foundation, or any kind of apianary supplies. Titles to property are good.
Address B. G. LUTTRELL,
Luttrell, De Kalb Co., Ala.

WANTED.—To exchange eight thoroughbred Newfoundland pups or eight Yorkshire pigs, for hives, sections, or foundation. Satisfaction guaranteed.
D. C. SULLIVAN,
11d Ridgeway, Orleans Co., N. Y.

WANTED.—To exchange English lop-ear rabbits, Guinea pigs, and water-spaniel dog pups for bees by the pound.
F. GROSSMAN,
11tfdb Kamm, Cuyahoga Co., O.

WANTED.—To exchange tested, untested, or mated pure-bred Italian queens, for a watch.
11d A. P. STAIR, Whitney, St. Clair Co., Ala.

WANTED.—To exchange 400 two-piece and 400 one-piece 5 $\frac{1}{4}$ x 6 $\frac{1}{4}$ V-groove secs., for 1000 4 $\frac{1}{4}$ x 4 $\frac{1}{4}$ Forncrook one-piece secs. (send sample); or for 5 purely mated Italian queens, daughters of imported mothers. J. M. YOUNG, Rock Bluffs, Neb. 11-12

WANTED.—To exchange, a good rifle and an opera-glass for Italian, Cyprian, or Albino (imported or home-bred queens) bees. Address
11tfdb OTTO KLEINOW, Detroit, Mich.

WANTED.—To exchange a pair of bantams for tested Italian or Holy-Land queen and a pound of bees.
FRANK SHILLING,
Jewett, Harrison Co., O.

WANTED.—Situation at once by a first-class bee-keeper who thoroughly understands his business.
FRANK CURL, 414 8th St., Des Moines, Ia.

WANTED.—Price lists from importers of Italian queens; also your names and address on postal for my circular of queens, etc., for 1887.
11d S. H. BLOSSER, Dayton, Rockingham Co., Va.

WANTED.—To exchange my new catalogue of bees, queens, new section-case, for your address on a postal card. Address F. A. EATON,
11-12d Bluffton, Allen Co., O.

WANTED.—To exchange, hives, sections, frames, crates, etc. (either flat or nailed), for white paint, box nails, foundation, belting, or any thing I can use. Send for free catalogue.
9-11-13d C. W. COSTELLO, Waterboro, Me.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will insert notices free of charge, as below. We do this bee-use there is hardly value enough to these queens to pay for buying them up and keeping them in stock; and yet it is often times quite an accommodation to those who can not afford higher-priced ones.

I have five black queens I will send to one address for one dollar. W. P. DAVIS, Goodman, N. C.

I have half a dozen mismated Italian queens for 40 cents apiece, or \$2.00 for the lot.
J. T. VAN PETTEN, Linn, Kansas.

I have a few good hybrid queens, ready by return mail, at 40 cents each.
JAMES H. EATON, Bluffton, O.

I have some fine Italian hybrid queens now ready to mail at 50 cents each, and guarantee safe delivery.
N. A. KNAPP, Rochester, Lorain Co., O.

Hybrid queens, reared from select tested Italian mother, for sale at 50 cts. each. Safe arrival and satisfaction guaranteed. GEO. W. BECKHAM,
8-9-10d Pleasant Hill, Lancaster Co., S. C.

SEE HERE!—60 black and hybrid queens for sale; are good laying queens, nearly all young, and are sold to make room for Italians. Ready now. Satisfaction and safe arrival guaranteed. Return all dead queens in same cage; all clipped. Price 30 and 45 cts.
L. T. AYERS,
Box 657, Kankakee, Kankakee Co., Ill.

During the coming summer I wish to requenee my apiary (almost entirely), and would sell my present stock of queens (all reared from imported mothers, Root's importations) from at 35 to 50 cents each, or 3 for \$1.00, to one address; and if any one gives me a trial, I will give satisfaction for any thing reasonable.
ELIAS COLE, Ashley, Delaware Co., O.

A Cheap Smoker.

MARTINSVILLE, O., Apr. 11, 1887.
Messrs. Bingham & Hetherington, Abronia, Mich.:
Enclosed find \$2.50 for two large 2 $\frac{1}{2}$ -inch Bingham smokers (wide shield). They are for my neighbors. I have one of the Bingham smokers that I have used for six years, and it is as good as ever. Send for half-dozen rates.
Respectfully, AMOS R. GARNER.

KIND WORDS FROM OUR CUSTOMERS.

I received the tin separators and foundation, and think the latter is exceedingly fine. Freight charges were 87 cts. CLYDE BELL.

Clarksville, Ind., May 13, 1887.

THOSE SPECTACLES.

I received the spectacles I ordered from you, and they suit me better than any other that I have yet found, although I have bought several pair at a higher price. G. B. SHANKLIN.

Zoneton, Ky., May 8, 1887.

THE NEW LAWN-MOWER AHEAD OF ALL OTHERS.

Mower received Monday night at 5:30—quick work. It is the nicest-working machine I ever used, and I have worn out some that cost \$12.50 to \$20.00. You can say for me, that, no matter what the price may be, no mower of the size can surpass it in any point. J. E. POND.

Foxboro, Mass., May 23, 1887.

THE FINEST MAPLE SUGAR.

Inclosed please find check to balance account. The goods sent me were satisfactory in every way. The maple sugar was the finest I ever melted in the N. E. corner of my mouth. I judge your impression of Holly is not very good. I live three miles from there. It is like most other towns—good and bad, and too much of the latter.

Holly, Mich., May 11, 1887. GEO. F. BRONDIGE.

A PLEASSED CUSTOMER.

I am under obligations to write to you, and words are inadequate to express my sincere thanks for your kindness in sending the A B C book. I don't feel that I ought to accept it for the damage to the saw, as the book is worth twice the amount the saw cost, and I am willing to pay you something for the work. I would further say, it is a truly wonderful treatise on bee culture. It is a delight to read it, besides the great information it gives in every department pertaining to the subject. A. CROOK.

Rosamond, Ind., May 30, 1887.

"A LONG WAY AHEAD."

I am just in receipt of goods ordered from you by freight. Everything is satisfactory and first class. I know it is a good long distance to send for this class of goods; but when you come to put them together, and use them, they are a long way ahead of any thing else I have seen manufactured in this region and I am more than pleased with your prices and goods. Accept thanks. J. SWIFT.

State Center, Ia., May 17, 1887.

I received your card, stating that you would ship the bees May 16. I received them May 18th at night, in good condition. Thanks for your promptness. I put the bees up in a hive that had been robbed. They went to work immediately, and are still at work. I am well pleased with them. If I can learn how to keep my bees from being robbed, I shall be very thankful. E. W. PETTYS.

Windsor, Broome Co., N. Y., May 20, 1887.

[See "Robbing," in the A B C.]

POTATO BOXES

(TERRY'S).

These are made of basswood, bound with galvanized iron. The galvanized iron gives strength, and the basswood strength and lightness. These hold exactly a bushel when level full, and may be piled one on top of another. Al-

though they are made especially for potatoes, they can be used for fruit, vegetables, picking up stones on the farm, and a thousand other purposes. When piled one above the other, they protect the contents from the sun and rain; and from their shape a great many more bushels can be set into a wagon than where baskets are used. They are also much more substantial than baskets.

Price 25 c each; 10, \$2.25; 100, \$20.00. In the flat, including nails and galvanized iron, \$1.75 for 10; 100, \$16.50; 1000, \$150.

A. I. ROOT. Medina, O.

Choice Italian Queens.

One untested, 75 cents; six, \$4.00; twelve, \$7.00. Tested, \$1.00, from natural swarming. 12-16db

HONEY COLUMN.

CITY MARKETS.

DETROIT.—*Honey.*—There is no good comb honey in the market to quote. *Beeswax*, 23 to 24c.
June 10. Bell Branch, Mich. M. H. HUNT.

CHICAGO.—*Honey.*—Very little comb honey here now; but what is offered is not prime and prices are unchanged. The demand for all grades is small. Extracted 5@6; selling more freely.

Beeswax, 22c. R. A. BURNETT,
June 3. Chicago, Ill.

PHILADELPHIA.—*Honey.*—Honey is in very light request and prices merely nominal. The only inquiry whatever is for 1-lb. sections of choice goods; in other descriptions there is absolutely no movement.

Beeswax is in light request and quotable at 22@24c per lb. for pure Southern; and 20@22c per lb. for pure Western
PANCOAST & GRIFFITHS,
June 10. 122 Dock St., Philadelphia, Pa.

BOSTON.—*Honey.*—No change in prices. Sale very slow.
BLAKE & RIPLEY,
June 10. Boston, Mass.

KANSAS CITY.—*Honey.*—Our market is almost bare of honey. Waiting now for the new crop.
June 11. CLEMONS, CLOON & Co.,
Kansas City, Mo.

CLEVELAND.—*Honey.*—The market is dull, there being no movement in honey; dealers are awaiting the new crop. Prices unchanged.

June 11. A. C. KENDEL,
Cleveland, Ohio.

ST. LOUIS.—*Honey.*—California has advanced her price on extracted honey which I think will give us a little better outlet for our home product in the near future. Extracted is already a little firmer. Comb honey, a large stock still on hand; choice white comb, 1-lb. sections, 10c; off, 8@9c. Broken comb, 6@7. *Beeswax*, 21; selected, 23@25.

June 10. W. B. WESCOTT & Co.,
St. Louis, Mo.

MILWAUKEE.—*Honey.*—The old crop is getting nearly out of sight; supply very small, and demand limited; and values have undergone very little change. Choice white comb, 1-lb. sections, 12@12½; choice white comb, 2-lb. sections, 10@11. Dark comb not wanted; entirely nominal. Extracted, finest white in kegs and pails, 6½@7c; same in bbls. and half-bbls., 6@6½; finest amber in bbls., 4¼@5; dark in bbls., 4@4½. *Beeswax*, nominal, 25c.

June 10. A. V. BISHOP,
Milwaukee, Wis.

ST. LOUIS.—*Honey.*—We quote choice comb 9@11 cts.; latter is for choice white clover in good condition. Strained in bbls. 3¼@4 cts. Extra fancy, of bright color and in No. 1 packages, ¼ ct. advance on above. Extracted in bbls., 4¼@4½ cts.; in cans, 5 cts. Market dull and receipts increasing.

Beeswax steady at 21 cts. for prime.
June 10. D. G. TUTT & Co.,
206 N. Commercial St., St. Louis, Mo.

CINCINNATI.—*Honey.*—Demand for comb is slow and prices are nominal. Demand for extracted honey from manufacturers is improving. No change in prices. It brings 3@7 cts. a lb. on arrival. There is a good demand for *Beeswax* which brings 23@22 cts. a lb. on arrival.

June 13. C. F. MUTH & SON,
Cincinnati, Ohio.

I have 400 lbs. of nice comb honey in one-pound sections, for sale cheap, if bought soon.
LOUIS WERNER, Edwardsville, Ill.

LOOK HERE!

Hayen sells tested queens for \$1.25; untested, 75 cents. 2 frame, \$2.10; 3 frame, \$3.00; 4 frame, \$4.00. Full colony, \$6.00. Bees 75 cents per pound. All prepaid. Add queen you want to the above.
12tfdb W. G. HAYEN, Pleasant Mound, Ill.

CARNIOLANS.

GENTLEST, BEST HONEY-GATHERERS, AND THE QUEENS THE MOST PROLIFIC OF ANY KNOWN RACE.

TIMELY SUGGESTIONS ON THE USE OF THE T SUPER.

WHEN TO PUT ON AND WHEN TO TAKE OFF THE HIVE, ETC.

SINCE the T super has taken such a boom, beginners and others have requested more especial instructions as to how to put in the sections, exactly when and how to put the first super on, when to add another, about how many a colony could take care of to advantage, and when to take the supers off, and finally when to remove them all. As there seemed to be no one more fitted or competent to answer the foregoing questions, we requested Dr. Miller to give minute directions, and to give every little manipulation just as if he were talking to beginners. We fancy that some of the veterans will find some directions from the doctor that will be of some service to them. Without any preliminaries whatever, he proceeds as follows:

Until you get the knack of it, putting sections in T supers is a little awkward. Have the supers on some plane surface, where the sections can't fall through if the tin T's are displaced. Place the T's not very carefully over the sheet-iron supports. Put a row of four sections (I'm supposing you use $4\frac{1}{4} \times 4\frac{1}{4}$ sections) along the side, which will fix the T's in their places at that side of the super; now a second row next the first, but leave a little space between them, and then slip a separator in the space. Continue in this way, pushing the rows close together as more room is needed. Supposing that you commenced filling the side of the super next to you (the *side* and not the *end* of the super must be next you), the rows will be pushed togeth-

er till only two rows are lacking, then put in a row close to the side next to you; then put two sections at one end of the last row, and one at the other, leaving the super full, all but one section. Putting in this last section is the hardest part; and unless your super is roomy, you will give up T supers in disgust and say it is too hard work to fill them. Don't hurry the section in, but push it down steadily, holding it square in its place, and it may go in with no trouble. One end, however, may catch on one of the T's, and you must raise the section the least trifle and crowd it enough to one side to allow it to pass down beside the objecting T. Sometimes it may be necessary to use a case-knife, pushing down the section till one side is caught inside its T, then pushing down the knife inside the T at the other end of the sections, when the latter can be crowded into its place. My assistant, who has had more experience than I in filling supers, says she latterly prefers to put first a row of sections in the side of the super furthest from her, the same as I have already described, and, next, to put a row in the side next to her, thus holding the T's in their place for the rest of the work. Then the last two separators can be coaxed into place, commencing at one end, but taking care that this end does not get much the start of the other, or the separator will be wedged fast. Possibly there may be so loose a fit that one or both of these last two separators may be put in before the last row of sections.

The general rule given for putting on sections is when bits of white wax are seen along the tops of the frames. I would rather not wait for this. Where clover is the first surplus crop it is well to put on supers when clover-bloom is out in full. This, at least in my locality, occurs ten days or two weeks after the first clover-blossoms are seen; but

if you do not keep a sharp lookout you may not see these first blossoms. It is a decided advantage to replace one of the central sections in the first super with a section partly filled that has been kept over from the previous season. You will find such a section occupied very promptly; and although the bees may empty all the honey out of it, they will still remain, at least a few of them, on it; and as soon as they have a surplus to dispose of they will commence refilling this section. It is possible that an empty section from which the honey has been emptied the previous fall may do nearly or quite as well, but I have never tried it.

When the first super is well filled with bees, and the work well started, the sections perhaps half filled, a second super should be added. Perhaps that does not give exactly the right idea. On one hive the super may be almost filled with honey, and the colony not yet ready for a second super, while another colony may be ready for a second super before its first super is more than a quarter filled. If a colony is very strong, and seems to have more than enough bees to occupy one super, if the honey-flow is good and likely to continue, it may be well to add a second super in a short time after the first, even if little has been stored in the first. This second super is to be placed under the first, which is raised for this purpose, and the bees will immediately occupy it. Indeed, I have added supers thus in rapid succession, always putting the empty one next the brood-nest, until the bees were working in six supers at once, and, as a result, I had six supers mostly filled with unfinished sections. The strongest colonies will not often need more than three supers at a time; for before the fourth is needed, the first is ready to be taken off. Don't wait for every section in the super to be finished before taking off; for if you wait for the outside ones to be finished, the central ones will become dark. When all but six or eight of the outside ones are sealed over, take off the super and return the unfinished ones, to be finished in another super. Whilst at the beginning of the harvest, the effort should be to urge the bees to occupy a large number of sections as quickly as possible; when the harvest begins to wane, the opposite course should be pursued. Here is a colony, for instance, that has about filled all its sections, but they are not capped over. If these are raised up, and a super of empty sections put under, the bees will commence work on the empty ones, and the honey-flow may stop before the upper sections are finished. On the other hand, if no empty sections are given, the honey-flow may continue longer than anticipated, and the bees become crowded for room. So, toward the last of the season, instead of putting the empty sections under, put them on top. The bees will go on finishing the sections already occupied, nearly if not quite as well as if no super had been put on top. If the bees need more room they will go up into the upper super, and if they don't need it they will let it alone. When the honey-flow ceases (and you will tell it by the bees becoming cross, and robbers troubling), it is best to take off all the sections, making a clean sweep of it.

Friend Root, you said my little book was lacking in pictures, and I never jawed back a word. But, now, you have put Hutchinson's book along with it, and I don't think that's fair. I don't think I ever so fully appreciated the educating power of an illustration as I have since your insisting upon

it so strongly, and I know of more than one place in my book where I studied how to clearly describe something till my head ached, that a picture would have cleared up in a twinkling. But in Hutchinson's book I can hardly see the same need of pictures. It is merely a new use of old things, and I am not sure that illustrations would help much. The chief purpose of the book was to give in full a peculiar system of management, and I am glad, very glad, to add it to my small collection of books on bee culture. He has told his story very concisely; and whether I follow his plan or not, if I want it at any time I can find it in compact form without hunting through all the pages of the periodicals. Then if you must have pictures, the cover of the book is itself a beautiful one. I know I wouldn't take 25 cts. for my copy. C. C. MILLER.

Marengo, Ill.

SOMETHING SEASONABLE AND VALUABLE FROM M. S. ROOT.

SWARMS ENTERING EMPTY HIVES.

MY brother, M. S. Root, now of National City, San Diego Co., California, sends me the following letter, which was written to himself. Some of our readers will doubtless remember, that on page 608 last year, my brother related an experience similar to the following:

M. S. Root:—In reading GLEANINGS I saw you had some notion of embarking in the bee-business. Now, let me give you a little circumstance that may be to you a benefit. My nephew and I kept bees, but concluded to divide, so he took his off and sold all the bees; but there were some boxes left, and some comb. To save the comb from the moth he put three or four in a box spread out evenly, so they did not touch by 2 inches. He then piled the hives or boxes four and six high, so that it looked like the stump of a tree. This is the way we save comb in or out of doors, in this country.

One day, in course of time he walked out to see if his comb was keeping all right, when he saw some bees in one tier. On lifting the lid there was a veritable swarm of Italian bees, so he took the box, put in some more frames, and set it out for business. He concluded to go through and see if there were any more, and kept on till he fixed up six good swarms. In a few days he went back again and found some more in. About the time swarming season was over he had 17 good swarms, with no effort on his part to collect them. There was no chance for the old bees to come back, as they were hauled three days' journey off. This may be too late for your neighborhood for this season, but I have been very busy. My bees have not swarmed much—only about 8 or 10 this season.

J. N. GILCHRIST.

El Montecito, Santa Barbara Co., Cal.

Many thanks, brother Marsh. The item you furnish is, I opine, one of much value. I suppose your correspondent uses the terms "boxes" where he means hives—or, at least, we would call them hives. The point is this: He by accident stacked up his empty hives in tiers, so they resembled trees in the forest. Each hive contained three or four combs, placed far enough apart to be safe from the moth-miller. The entrances to these hives were also left open. Now, it is

my opinion that the arrangement will work in any neighborhood where many bees are kept. I would suggest, however, having the hives in the shade of trees—say scattered through an apple-orchard, or run the tiers up so as to be among the branches of the trees. There will be little or no danger from moth-millers, for the combs are kept at least two inches from each other. I should suppose the bees would be more likely to occupy the hives toward the top, or those up among the limbs of the trees. Many of our readers will remember that our friend J. H. Martin, of Hartford, N. Y., advocated placing hives in the tree-tops, a good many years ago. Every little while we have reports of new swarms taking possession of hives left ready for them during swarming time; and now it only remains for some enterprising bee-man to push this matter forward to success. Suppose we have as many facts as can be furnished on the subject; and as it is now swarming time, let us all experiment a little in regard to the matter. We will have some hives put up among our evergreens at once; and instead of having the bees bother us by clustering among the evergreen branches, as they do almost every season, hold them clustered on metal-cornered frames of comb. As there has been considerable trouble in our apiary lately, from bees missing their location and getting into neighboring hives, a few hives set among the evergreens might be a help, after they catch a truant swarm apiece.

ILLUSTRATIONS.

FRIEND HUTCHINSON'S REPLY TO ANSWERS AND QUESTIONS REGARDING HIS NEW BOOK.

IT is possible, friend Root, that you are correct about the need of cuts in my little book; I can not help thinking, though, that the majority of those you mention, if not the whole of them, would be superfluous. I am thankful, though, for the criticisms, and I wish to say right here that I should be grateful to any one who will write and tell me where he thinks a cut might be used to advantage; or, in fact, where he would have the book different in any manner; and if there is any point that is not fully understood, I shall be happy to explain, either by private correspondence or through the journals; and all the points that are brought up shall be well considered in a re-issue. I should enjoy very much indeed the work of getting up first-class engravings for a book of my own writing. You say, friend Root, that, had I added nice engravings, the book would have started out with a great boom. It seems to me that it has started out with a pretty good-sized boom as it is, as 1000 copies have already been sold, and the sale increases with each week, while every mail brings complimentary letters from pleased purchasers.

CONTRACTING THE BROOD-NEST.

On page 431, Mr. Gould asks me to explain why the brood-nest should be so contracted as to be low and flat instead of tall and thin. If side storing were practiced, the tall and thin style would be all right; but with top storing only, the space above the brood-nest is too small to give room for a sufficient number of boxes. Bees work the best in

boxes when the brood is near the boxes; and it will be readily seen that a low flat brood-nest gives the greatest possible opportunity for placing a large number of boxes in proximity to the brood. My objection to side storing is, that it adds considerably to the complication of fixtures, and very much to the labor.

Mr. Gould's plan of dividing colonies and allowing the bees to build combs in the brood-nest will probably prove satisfactory unless done just upon the eve of swarming, when drone comb would be the result. If done earlier, when the queen is laying in full vigor, most of the comb built would probably be worker, unless the queen were old.

MAKING FEEDERS WATER-TIGHT.

Let me tell Dr. Miller that he can make feeders water-tight by so putting them together that one piece can not shrink away from another, and painting the joints with white lead before putting them together. I have 60 Heddon feeders that I made three years ago, and they have never given a particle of trouble by leaking. Let me also add, that in "feeding back" there must be no space in the hive or about the feeder that is more than "bee-space," or it will be filled with comb. At no time are bees so prone to build brace-combs as when being fed abundantly.

W. Z. HUTCHINSON.

Rogersville, Mich., June 6, 1887.

There seems to be a sort of feeling among newspaper men that an editor should never own up to having made a mistake, and never apologize if he can possibly help it. I once heard of a man whose death was published in the village paper. He repaired at once to the editorial sanctum, and commenced something like this:

"Mr. Editor, you published in your paper last week a notice of my death."

The editor nodded, and the man went on:

"Well, you see I am not dead."

"We see that you are alive now," replied the editor, evading the question, as you will observe.

"But," said the man, "I haven't been dead at all; in fact, I haven't even been sick, and I want you to state it so in your next issue."

"We are quite willing to say you have come to life," replied the editor, "but we can not very well say that you have not been dead. It is hardly possible we should have so stated it in the paper unless it were a fact." And our friend from the country was obliged to go away without getting any better satisfaction than the above. Now, although I have never seen any thing quite as bad as this, I have been very many times greatly pained to notice the reluctance with which an editor admits that he has been even a little mistaken. Please look back and remember how seldom any editor has frankly owned up that he had published a mistake in regard to this matter of bogus comb honey. It does not seem to be fashionable to say right out in print, "We were hasty," or, "We were entirely in the wrong, please excuse us." Perhaps you may wonder, dear friends, what all this has to do with friend Hutchinson's article above. Well, it has just this to do with it: In criticising his book because of the lack of cuts, I thoughtlessly bore on stronger than I should have done, and I want the readers of GLEANINGS to forgive me, as well as friend

H. himself. After I had dictated the reply, I had a feeling that I had been a little off from the track; and when it occurred to me, I hastened back to the office to have the reply cut down, or taken out entirely; but it was already on the press, and could not be changed. For my part, I should like to see the book illustrated in the way I suggested; but when I said it needed as many illustrations as there were pages I was probably extravagant. The book has had quite a boom, if you have already sold one thousand.

Now in regard to this other matter: I am always glad to see the editors fully alive to every item that appears in their publication; but it makes me feel sad to see them set a bad example before their readers, by getting into controversies. Editors are, however, human, like other people; and may God give me enough grace and honesty of purpose to own up frankly whenever I have transgressed, or said more than I intended.

OUR P. BENSON LETTER.

HIVIN JENNY'S SWARM.

JENNY gathered up sum moar tin ware includin a horn, and when all were set agoin you jist ot to herd em. My! if it wuzzent a racket. But before this, Jack hed drawed a bead on the swarm with his gun and let fly, sayin, "If that air charge hits the old king in the face, ittle spoil his snoot for him."

As mife be naterally expected with sitch a racket, the bees soon was all lit onto the lim. "She's a snolly-goster," sez Sid. She ment it wuz a big swarm. "Why, thuz mourn 2 bushel of bees," sez Em. "Whattle I ever git em into?" sez Jenny. "Git a barl," sez Mary. So they got a barl that was layin down on its side for a hen's nest, but just then Jenny's bruther Will got home and sed that was his hen's nest and they coodent no swarm of bees go into it, not onlest he cood hev a peace of hunny. Jenny fincly had to promicce him the last piece of hunny they made, and the barl was sot under the swarm. "Now you must have a sheet under it," sez Mary. "Woont a table cloth do?" sez Jenny. "No, it must be a sheet." So she got the sheet and poot it under the barl and poot a cupple of sticks of fire wood under the ej of the barl. Then it was who shood shaik them down. "Jack izzent afeerd," sez Em. "What if they should take after a feller?" sez Jack. "I ges you kin run," sez Mary. So Jack took a long pole, and the rest all stood back, and he hights the pole kind a carefull like, shets his ize and makes 1 quick jab at the lim, and then drops the pole and runs like the hole swarm was after him. Then they all laffed for he had missed the limb and Jack cum back and tride it agane. This time he hit the lim and sum of the swarm fell on the ground, but floo back onto the lim. "The barl aint in the rite place," sez Jenny. "Rub it with tanzey and thale go in," sez Em. Will got sum tanzey and rubbed the barl, and poot it in the rite place, but before he hed time to git back out of the way, Jack give the lim a offle big punch and down cum the hole swarm, sum of em rite onto Will. "Mercy me, I got to git outa this," sez Will and he begun to scatter lively. Jack poot boath hands on his nees and jest doubled himself up a laffin at Will, when just then 2 or 3 bees steered straight for Jack. Run!

I guess he dld run. Boath hands a flyin like a windmill, a strikin his hair and a nockin off his hat. Thay coodent coax him back no way. "Cum and see them croll into the barl," sez Will. "No, I haint well," sez Jack. "I got to go home and do my chores. Sid, bring my gun and hat with you."

HIS HANDS FLYIN LIKE A WINDMILL.

In a little while the bees was pirty much all in the barl, and the ooddyence was admirin them when 1 of the dogs, being of a inquiring turn, came in ruther close propinkquity. A bee lit onto his back and that dog gave 1 yelp and jumped mourn 10 feet into the air. When he cum down he gave another yelp and then he looked aroun to see whair the coal of fire was on his back. Then he broke for the woods like a streak of greese litenin, evry spring givin a yelp, and it was 10 days before that dog got back home, lookin like hede bin throo a corn sheller.

P. BENSON, A. B. S.

Konkluded.

DOOLITTLE DISPUTED.

THE PIPING OF QUEENS.

I THINK G. M. Doolittle is justly considered good authority on most questions pertaining to bee culture, and the man who calls in question any assertion he makes ought to be well posted on the disputed point, and know whereof he affirms. I have been a bee-keeper for more than 30 years, and positively know that his theory (see page 434, June 1st) in regard to after-swarms and piping queens is not correct. I agree with him as to the time between the issue of the first swarm and the piping of the first queen, and the issuing of the second swarm, which, as he says, will take place with almost mathematical accuracy in nine or ten days from the first swarm; but I most emphatically deny that there is only one queen allowed to leave the queen-cells at a time, or that only one pipes at a time, or that, as a rule, only one queen accompanies the second, third, or, in fact, any after-swarm. I know it, because I have many times heard two or more queens piping at the same time. I have seen and caught several in the same swarm, and I almost always find one or more dead queens under the hive when it is moved to its stand after hiving an after-swarm. There may be exceptions; but as a rule there will be two or more queens with after-swarms, but more especially third and fourth swarms. Friend D., examine this question and report.

A DEWEY.

Marshfield, Pa., June, 1887.

SUITABLE DRESS FOR WORK AMONG THE BEES IN HOT WEATHER.

FURTHER HINTS AND SUGGESTIONS FROM DR. MILLER.

THE following letter was sent to me from Dr. Miller. It was not written for publication; but as it contains so many matters of interest, we give it below:

Dear Ernest:—Your article on page 30 interests me much. I am glad to see you getting down to the minutiae—to the little details. I strongly suspect, that in hot weather woolen may be better for next the skin, and that you are right, both for fat and lean people. I am making some inquiries that may help us out.

I once had a hat of the same kind, I think, as you describe. I do not think I like it so well as the five-cent hat I use. Their cost is so little that I generally keep a set at each apiary, a veil being sewed to the rim of each. My wife says you would not wear one, "they are such awful-looking things." It is true, they are not models of beauty, after being worn awhile, especially after being wet. They present an appearance something like this:

I like them better, however, after they assume this drooping habit. They shade the face and eyes better, and hold the veil in better shape. They have a look of such abject humility that no one is likely to be very hard on you for anything you have done, while you are covered by one of them.

I wish you would try a pair of Newburgh (N. Y.) overalls. They are thoroughly made, no button ever comes off. Each button about the waist has plainly stamped upon it, "Newburgh Overall." The material is good, and they are neatly fitting; in fact, they are a standard article.

You have said nothing about the suspenders. An article of good, substantial, *easy* suspenders at low cost is something very much needed. I doubt if the right thing is yet invented. It should be something that will admit of stooping forward without lifting you out of your seat or tearing off the back buttons. This is usually accomplished to a certain extent by the use of rubber. The rubber, however, is not durable, and becomes worthless with age, even if not used at all, and I want a pair of suspenders fitted to each pair of pants, to avoid adjusting them each time I change; and this makes it that, on a pair of pants but little used, the rubber is spoiled while the suspenders are very little worn. I think the right suspender will have no rubber in it. I have worn several pairs of Argosy suspenders, made with cords and pulleys, without rubber, and like them well, but they are expensive, costing 50 cts., and the cord wears through in some spot before long, and then the whole thing must be thrown aside.

Once while I was sitting in an office in Chicago, a man came in with a pair of patent suspenders, in-

tended to cover the difficulty by maintaining the same easy feeling, no matter what position the wearer took. I tried on a pair, and they certainly were a success. I have since been sorry I did not buy a pair, as I have never seen any like them since. There was some sort of a patent device attached, which it was claimed secured the proper adjustment upon any change of position, but I doubt if this device had any thing to do with it. I think it was simply the way in which the suspenders were fastened on the pants.

Since writing the above I have been experimenting a little, and I think I have hit upon the principle used in the suspenders last mentioned. Move the two back suspender buttons 6 or 8 inches further apart, and use only the hindmost of the two front buttons on each side; in other words, have no buttons before or behind, but two at each side, three or four inches apart. Now put on a pair of the plainest kind of suspenders, crossed on the back in the old-fashioned way, and I believe you will find them easy for the stooping so common about beework.

Now let John get us, on the 15 or 20 cent counter, a pair of stout suspenders that are made of one straight plain piece—no rubber, but heavy enough to remain pretty rigid, with *strong* leather at each end. Possibly there may be an advantage in having the two buttons at each side in front; that is, having each front end of the suspender attached to two buttons.

Since the above was written I have made inquiry as to the matter of cotton or woolen clothing for those exposed to extreme heat. My brother-in-law is superintendent of iron and steel works, having two or three thousand men under his control (from the miners to the last workers on steel), and he says all his experience is in favor of woolen clothing. The only men he knows of who don't wear woolen shirts when so exposed are puddlers, and they strip to the waist; but as a very general thing they wear woolen drawers. That is the result of an experience among iron and steel workers extending over thirty years.

C. C. MILLER.

Marengo, Ill.

Many thanks, friend M., for your kind letter. I am still wearing the underwear I spoke of on page 30, current volume; but I have not seen the day this spring that I desired to take it off, and we have had days when the thermometer registered over 90°, even in the month of May. You know, that when warm weather comes very suddenly in the season we feel the heat much more. While others were complaining about the very hot weather, I don't think I experienced any inconvenience. I know of several who are wearing underwear, and they claim that it is not only better on very hot days, but quite a protection when the weather changes suddenly, and the air feels chilly and damp. I do not know, but suspect, that the great majority of those who are exposed to a considerable amount of sun heat or artificial heat would be a great deal better off with light underwear. I know that I have not, for the past few years, suffered so much from the heat as I formerly did when I removed all underwear at the approach of hot weather. I think it is a fact everywhere, that where men are obliged to work with and around melted metals or blast-furnaces,

DR. MILLER'S BEE HAT AND VEIL.

you will find them wearing woolen; and I see no reason why, if this class of men find need of this additional protection, bee-keepers and others exposed to the direct rays of the sun should not have a similar protection. In regard to the headwear, I presume, friend M., you take a good deal of comfort in that old hat or hats. I like a hat that is light, not unbecoming, porous, one that does not produce any pressure around the crown, and which will keep its shape, rain or no rain. The bee-keeper's hat, which I like so well, is made of linen; and when it is on my head, during a hot day, I can feel the cool breezes circulate through my hair. It is so light that I scarcely know when I have it on; and for the sake of convenience I wear it all the time, in the office and out of doors. I notice, also, that the men in the field, those making garden, working among the bees, or piling lumber, are beginning to wear them quite generally around the Home of the Honey-Bees.—In this connection I might mention that those light rubber boots, designed for ladies, are just the thing for wading in the grass, and for doing light work among the bees. Yesterday, during the rain, when we were locating some bees in the Swamp Apiary, it was raining; and as there was long tall grass and weeds, I should have gotten the bottoms of my pantaloons pretty well soaked had I not worn these light rubber boots. Lest, however, some one may take a notion to order said boots of us, I will say that, although we sell almost every thing under the sun, we don't want to have any thing to do with selling boots.

CARPETS VS. BARE FLOORS.

FRIEND TERRY CONSIDERS BOTH SIDES OF THE SUBJECT.

FRRIEND ROOT:—At a number of farmers' institutes last winter, speakers brought up the question as to whether it would not be better for our health to abolish carpets from our houses. One of the strongest attacks on this way of covering the floor was made by an eloquent clergyman at the central institute at Columbus. I also heard a well-known professor wax eloquent over bare floors and rugs, and tell how unhealthful it is to have floors covered with carpets. He was evidently in earnest, as I found, when calling at his office, a bare floor, except that there was a small rug under his chair and table. But he was a bachelor, and some one else besides his wife had to scrub the floors and shake the rug almost daily.

Now let us bring a little plain common sense to bear on this question. First, which is easier for the wife—to scrub floors or to sweep carpets? I think all will agree with me on the latter. It used to worry me greatly to see my wife mopping and scrubbing the floor in the kitchen of our old house, two or three times a week. Hence when I built a new one, and the carpenter asked if I wanted a hardwood floor in the kitchen and pantry, I told him, "No, sir; put in all pine floors." Since then, all floors have been carpeted, except in a store-room upstairs, and the porch floors. Even the latter I sometimes wish were carpeted, when I see my wife spending so much time keeping them clean. I

shouldn't wonder if she worked harder on those four porch floors than on all the carpeted floors in the house. Keeping carpets clean is a small job, since we have good carpet-sweepers. Once in a while, to be sure, wife has to go over those with a broom, in the old-fashioned way, and she never gave me any really satisfactory reason for it (I suspect it is partly a hankering after the way she was brought up in—mother's way); but usually a light running-over with the little sweeper takes up all dust in sight, and doesn't unnecessarily stir up what wasn't before in sight, to the discomfort of every one. This machine sweeping is very easy work, particularly if your correspondent keeps the bearings well oiled. It doesn't take the muscle that it used to, to scrub, and certainly the position occupied while at work is rather more dignified.

Which is the more comfortable floor to live on? The bare one, with here and there a rug, perhaps, or the one nicely covered with a good carpet? Well, for me, home without carpets would be almost as bad as without a mother. I presume the advocates of no carpets would agree with me pretty well in what has been said so far; but they would bring up the all-important point of healthfulness, and say that was to be considered first of all. Well, if carpets are injurious to our health, perhaps we had better go backward a little in our civilization. Let us see. What is the claim against them? So much dust containing injurious germs. A rug can be rolled up carefully and taken outdoors, and shaken. Floors can be washed, and no dust raised. Sweep a carpet that has been down for some time, and you fill the room with dust. These particles get into the lungs. They can take care of a moderate quantity and work them off, or keep them out; but when they come in too large quantities the door-keepers in the lungs are overpowered. If the germs in this dust are not positively injurious in themselves they may so use up the machinery provided by nature to ward them off that other germs that are injurious and that happen along, or to which one may be accidentally exposed, are able to get a lodgment. This, I believe, is about the ground taken by the scientific opposers of carpets. It seems plausible; but I doubt, practically, whether one needs to abolish carpets on this ground. Now, our homes should always be kept dry. Fires should begin early in the fall, and be kept up late in the spring. A little, once in a while, during a cool time in the summer, would be wise. The dust collected under the carpets, so long as it is kept dry, and is not disturbed, will injure no one. The conditions are quite different from what they would be in a damp cellar during warm weather. The greater part of the dust under carpets is simply dirt or earth, that has been tracked in. There may be, and probably will be, under some conditions, some injurious matter; but kept dry it is quite harmless, particularly if let alone. When the housewife sweeps, then comes the danger—when the dust is stirred up so as to be floating thickly in the air she breathes. If she will see the matter as it is, and use a sweeper carefully, having doors and windows open when practical, so the wind can take out the dust necessarily raised, as much as possible, I think she may live to a ripe old age, for all of the dust imbibed. Any way, I would sooner my wife would die of too much dust in the lungs rather than of too much hard work scrubbing and mopping. I should feel less directly to blame. I

know that too much hard work kills many farmers' wives. I am not entirely certain about how many deaths are the result from carpet dust, under reasonable conditions. At any rate, the latter death would be the more dignified. It would sound best, if the truth were told at the funeral, and it does generally leak out around, now, if a man works his wife to death, even if the minister doesn't speak of it.

Seriously, I think this point of the unhealthfulness of carpets has been carried too far, according to our present knowledge, by some extremists. If the ladies will take up and clean the carpets, or, rather, see that the men clean them, when they get so they can not keep the surface reasonably clean without raising too much dust, and if they will use a good sweeper instead of a broom, as far as possible—in fact, bring their good common sense to bear on the matter, I think they may not fear to carpet every room in the house.

Of course, there are exceptional circumstances. If some member of the family were taken sick with some contagious disease, the carpet should be taken up immediately from the sick-room floor. Some breadths might be laid down, or some pieces, to prevent noise in walking, and then be shaken daily. This would give the sick one as pure air as possible, and the pieces could be destroyed when the patient got better, thus disposing of any germs of disease that may have found lodgment in the carpet; otherwise, at some future time, when the carpet is taken up, another member of the family might be stricken with the disease. On account of purer air it might be well to have only rugs in all sick-rooms, and a plain whitewashed wall would also be better than a papered one.

I visited at a home last winter where all the lower floor was covered with Brussels carpet, kitchen and all. The good wife did her own work, and her husband told me he found she could keep a Brussels carpet clean with less dust and sweeping, and he valued his wife more than his money. It is true, that no dust to speak of will go through these carpets; so this is a way to avoid dirt under the carpets. We took up one the other day that had been down nearly four years. An ingrain carpet would have got more under it in four weeks. I think seriously of getting them for dining and sitting rooms, as it will save so much taking up, etc. But I must stop or I shall have the men after me for getting their wives' ideas up too high. Never mind; the ladies will defend me with their brooms—no, carpet-sweepers, I mean. That is the only trouble with the sweepers—they are not so handy to drive out the dog with, or scare the hens off the porch.

My wife has read this, as she always does all my letters, before they are mailed. She says: "All right; send it along; but remember, I have got a clincher on you whenever I want a carpet cleaned, in the future." Well, I must own I had rather preach cleaning carpets than to practice. That is one reason in favor of the Brussels. Perhaps that man I told of was more selfish, after all, than careful of his wife.

T. B. TERRY.

Hudson, O., May 25, 1887.

Well done, old friend. Before I attempted to say a word in reply I just carried the proof-sheet over to the house, and sat down by the kitchen stove (even if it is the 2d of June a fire was rather comfortable) and de-

sired my wife to sit down while I put her through the catechism. Our kitchen and pantry have hard-wood floors, and we mean to keep the floors painted, but it has not been done. This mopping business is something that has annoyed me more than a little. While I was reading, one of the children went to get a drink of water, and some water dripped across the kitchen floor. My wife put after the mop, in spite of any thing I could say, and she would not hear me through until she had mopped up the clean water that had been dropped on the floor. She did not tell me what hurt the clean water would do, but the women-folks have some reason. She says she dislikes mopping; but carpets in the kitchen, where there are so many children as we have, get so awful dirty she can not tolerate them. If a hard floor is kept well painted, or soaked with beeswax, the labor of keeping it clean is very much less. I presume our bee-men can afford beeswax enough to wax the kitchen floor, if anybody can. So long as the floor is well waxed or painted, grease-spots, or any other thing, do little or no harm; but since the paint has got worn off, every spot of grease has to be scrubbed and got out. I can not tell why this is necessary, either. If it were my kitchen, I think I should let the grease soak into the wood as deep as it wanted to. I wouldn't have it get so bad that the children would slip down and grease their clothes, but I should be very glad indeed to have some arrangement devised for saving so much back-breaking work that must all be done by the queen of the home. I suggested Brussels carpets to Mrs. Root, but she asked where the dirt will go to if it does not get through the carpet on to the floor. I told her it would probably stay in the carpet, but she says she would not have that.

She wants to shake hands with your wife on that "clincher." She says if you succeed in getting the men-folks to take hold and even help to clean the carpets, the women of our land will owe you a big vote of thanks. Come to think of it, she did not use those very words, for she does not express herself as strongly as I do; but I am well enough acquainted with her so I know that is just about what she meant by what she did say.

In regard to porches, the house we always lived in before we moved into our present one had no porches at all; but, like yourself, when we built our present home we thought that lots of porches would be nice; but Mrs. Root says now, that, if she were going to have another house, she would cut the number of porches down to about two instead of four. Why, it seems as if all outdoors, pretty nearly, had conspired to make her use all her spare time in scrubbing the porches. Not only the children and the men-folks, but spiders and flies, have put their heads together to see how they could soil the porches most; and then, to cap the climax, the English sparrows discovered the porches were just the place to roost; and when they did not make trouble enough, they commenced building nests in them. I wonder if we can not have porches made of tile, or something that dirt would slip off from,

with little or no scrubbing. I think I have seen carpets on porches in some of the cities, laid down loosely, so as to be rolled up and carried in when it rains. Will not some of our lady contributors give us some suggestions in regard to these very important matters? No doubt the men-folks are greatly in need of reformation in this matter of lessening the labor of their wives; but I am afraid it is also true that many wives, through mistaken notions, overwork themselves.

WEDGING UP WIDE FRAMES.

WM. MUTH-RASMUSSEN'S WAY.

IN my supers I use, for the production of comb honey, 7 wide frames, holding 6 Simplicity sections each. Back of the wide frames I place a follower, or division-board, and behind this is a space of from $\frac{1}{4}$ to $\frac{1}{2}$ inch, averaging $\frac{3}{8}$ inch, in which I used to insert a wedge, in order to crowd the frames snugly together. The wedges were, however, very unsatisfactory, as each had to be fitted to its particular super, and while crowding the follower at the top they would often force it away from the wide frame at the bottom. Sometimes they would, when propolized, be very difficult to get out, and occasionally they would slip down out of reach.

At first I thought of using screws (*a la* Heddon) instead of wedges; but partly from an aversion to having the screw projecting outside the super, and partly because I saw so many conflicting reports about the desirability and practicability of screws, I came to the conclusion that a spring of the proper shape, strength, and cheapness was what was wanted.

MUTH-RASMUSSEN'S SUPER-SPRING AND HOOK.

I send you by this mail such a spring, and the accompanying drawings will more fully explain it. The perpendicular arm, A, Fig. 1, which stands at a right angle to the spring proper, serves two purposes; viz.: 1. In inserting the spring between the follower and the end of the super, and by placing the heel, C, of the hook, Fig. 2, on the perpendicular arm, at B, the spring is easily pushed down into its place. 2. The perpendicular arm prevents the spring from turning, when in place. To remove the spring, insert the flattened point, D, of the hook in the loop of the spring, at E, and pull up as shown in Fig. 3.

The hook is made of the same material as the

spring, and is hammered flat, from C to D, so as easily to enter the loop E.

For material, I used wire from an old spring-mattress. I first tried wire which had been burned, but found that I could not temper the springs. Wire which has not been burned answers, however, admirably. The bed-spring is first straightened out and cut into lengths of 8 inches. The horizontal arm is then bent in a vise. Next, the point G is slightly bent at a right angle to the horizontal arm, to prevent it from catching in the wood; and then the loop E is bent, partly in the vise and partly by hand. Finally, by placing a piece of iron or a small cold-chisel, between the prongs of the spring, and with a hammer tapping at I, the spring is given the right shape. It can be opened or compressed by hand to suit different distances, if it is either too large or too small; but if it has to be opened much it had better be done by bending it at I, as much bending at E, where the sharpest turn is made, might break it at that point.

WM. MUTH-RASMUSSEN.

Independence, Cal., May 5, 1887.

Friend M., your device is quite ingenious. The only objection I can make is, that it is a little complicated; that is, you are obliged to have these wire springs and a hook to pull them out with. I presume, however, a common button-hook would answer just as well, and these are to be found in almost every household. I quite agree with you, that I should not want any screws sticking out of the side of the super or honey-case. The springs you describe should be made by machinery, at a very small expense, and may be they are the best thing that can be devised for the purpose. Are we to understand that one spring is all you use to each division-board?

HEDDON'S LETTER.

SEPTIC DISEASES.

I COME to GLEANINGS with the above subject, which is not only of interest to my understanding, but my health and life as well. I find that some believe that radical impurities, in considerable quantities, will pass down through many feet of sand. I can hardly credit it. Here we dig through 25 feet of sand to water. Now, if an old privy-vault were six feet deep, and full, would its impurities ever lead down through the remaining 19 feet of sand, reaching the water? If so, how far away would the well have to be, to be out of danger of having its water thus tainted? Will Prof. Cook, Mr. Terry, or some one who *knows*, please give us his experience?

WIDE FRAMES.

I have noticed the clash of views between W. H. Shirley and yourself, as found on page 393, and I think that friend Shirley is nearer right. For several years we have used a few tin T cases, and, with the exception of first cost, I find every thing favoring the one-story wide frame, where separators are to be used. Where no separators are desired, our old-style case is so much better than all others that I can not improve it, nor do I find that any one can. All alterations have been found to be detrimental. As you say, my break-joint slat honey-board is a great protection to the sections above; but this is more against brace-combs than propolis, to which

Mr. Shirley has reference. When sections taken from a T super are cleaner than those taken from one-story wide frames, those wide frames are not properly constructed. T supers, in their best construction, can protect sections no better, nor as well, as my well-known surplus case; and Mr. Shirley has used hundreds of each side by side.

WINTERING.

My bees have wintered better than usual, and some in a higher and some in a lower temperature than heretofore. At the same time, a few, standing by the side of the successful ones, have died with diarrhea; and as temperature and humidity could not have been the cause, and as the excreta is pollen and water, I am still firmly grounded in the pollen theory.

WHOM SHALL WE TRUST?

I note the above in connection with the name of J. R. Reed, of Milford, Wis., on page 409. I have had most satisfactory dealings with Mr. Reed, and I wish the man success; not only because I believe him to be honest, but because he is a chronic invalid and needs the good reputation he has earned in his transactions with me. JAMES HEDDON.

Dowagiac, Mich.

Friend H., I am astonished at what you say in your opening paragraph; but as the subject is one of such vital importance I have decided to answer it by the article given below.—In regard to wide frames and T supers, my position was, for a good many years, that the wide frame afforded the best protection. So many were against me, however, I was compelled to give in a little in regard to T supers; but it seems now, friend H., you are getting back to where I used to be. The wide frame is, however, a more expensive arrangement than the T super.—I am very glad indeed to have you speak a good word for friend Reed. It is always a pleasure to me to recommend men for promptness and honesty.

THE WATER WE DRINK, ETC.

THE CONSIDERATION OF A QUESTION PROPOUNDED BY FRIEND HEDDON ON PREVIOUS PAGE.

I PRESUME friend Heddon has not had the experience in underdraining ground that friend Terry and myself have had. While visiting at Prof. Cook's I found he also had some splendid underdraining on his farm. Well, now, our soil is such a stiff clay that farmers dig holes in the lots, for watering cattle, that hold all summer; but for all that, we have proved by many experiments that underdrains will draw the water from 10 to 20 feet in each direction, the distance depending upon the depth of the underdrain. For instance, it is laid down in the books that underdrains 2 feet deep should be 20 feet apart; 3 feet deep, 30 feet apart; and 4 feet deep, 40 feet apart. When our underdrains were first put in, I was a little skeptical about the water finding its way to the underdrains as far as 20 feet off; but soon I found the water passed off from the surface of the ground quicker and quicker, indicating that the water had formed passageways, even down through the hard yellow clay subsoil. Now, if an

underdrain 4 feet deep drains the water out of the ground for 20 feet in each direction, what would an underdrain do that is 5 or 6 feet deep? Of course, there will be a limit somewhere; but I am inclined to think that a well that is 20 or more feet down to the surface of the water, will, in the process of years, take up surface water for a distance of several rods in every direction from the well. Now, then, the point friend Heddon makes is, would not this foul water become so thoroughly filtered in passing through such a mass of earth (or sand, as he terms it) as to be practically pure and fit for drinking when it reaches the water in the well? This would be the case for some little time after the well was first dug; but all who use filtering material are aware that, sooner or later, the filtering material becomes loaded, and does not act as a filter any longer. Now, if a privy-vault were only 25 feet away from the well, I feel quite satisfied that, in the course of four or five years, it would affect the water in the well. In sandy soils, I should think it might in less than one year. The microscope, I believe, will indicate positively whether the well-water contains matter of this description; and a great many times it is perceptible to the taste, that the water of certain wells has become contaminated by drainings from sinks, stables, pig-sties, or places such as friend H. has mentioned. There is one reason why the occupants of the dwelling do not notice it. By being accustomed to it day by day their perceptive faculties in regard to taste become so accustomed to it that it is not noticed. I remember, that, when I was a small boy, father and I went to a tannery. I said to him, "Father how can those people live in such an awful stench and smell?"

He asked one of the workmen how it was. The reply was, that they did not notice any smell at all; and father told me that, after I had remained there a little while, I would not notice it either, and I found it to be the case, and I presume many other people have remarked the same thing over and over. The people who are using water that has death and disease in it have become so gradually accustomed to it that they don't discover by the taste any thing amiss at all; a stranger, however, who has been accustomed to pure spring water would be sickened by a single glass, and would at once pronounce it unsafe.

I am inclined to think that the greater part of our fevers, especially the typhoid type, and possibly the class of throat diseases in the line of diphtheria, mostly have their origin and growth from carelessness in regard to the location of our wells. Many of the cisterns are but little better. I believe Mr. Terry has given us the remedy, but I am afraid that even that remedy is not a perfect one. There is one thing we can all do; and that is, we can have the ground around our wells descend outward in every direction. This will carry the rain water away, and standing water during spring time and winter. Having the ground around the well thoroughly underdrained, and a good free outlet, accomplishes a good deal in this direction. This surface water,

then is carried away, instead of getting down into the well for an outlet.

Very much greater pains is also being taken with sink-drains and cellar-drains. In the construction of the cellars for the two houses we are now building for John and Ernest, I talked the matter over a good deal with the builders, and those who are accustomed to such work, and they say it is nowadays customary to have the slop-drain of sewer-pipe from 4 to 6 inches in diameter, and this large tile is laid with a good strong fall, so that the slops pass off quickly and surely. Now, there is so much danger from foul gases coming up through this slop-drain that a separate drain is constructed for the cellar to drain off the surface water, so it shall not get into the cellar. In our case a ditch was dug under the cellar walls, a foot in depth; then a place for the tile was cut out into the bank, the tile being on a level with the bottom of said ditch. After the tile is laid, the ditch is filled with cobble-stones or broken wall-stones; and on top of this foot of loose stones the wall is placed. With such an arrangement you will notice that no water can possibly get into the cellar, for the cellar bottom is a foot higher than the tile that drains it. Slop-drains should also have some sort of a trap that will make it impossible for any gases to rise up into the cellar, or into any room of the building. These arrangements cost some money; but, my friend, how much money does it cost to have typhoid fever in your family? At one of our bee-conventions Prof. Cook had one of the college professors give us a talk on statistics; and in his talk we were told just how many more cases of typhoid fever occurred, when the water of the wells stood very low on account of a drought. The lower the water is in the wells, the greater is the tendency for foul waters to find a passage into them, for the reasons given in the fore part of this article. I should be very glad indeed to have both Prof. Cook and Mr. Terry say how far I am out of the way in the foregoing.

BLESSED ARE THEY THAT MOURN, FOR THEY SHALL BE COMFORTED.

SOMETHING FURTHER FROM BRO. G. C. STOKELY—
SEE OUR HOMES FOR MARCH 15.

MR. ROOT:—Allow me to acknowledge your tender of sympathy and Christian sentiments, kindly offered to one in dire distress. Although an utter stranger to you, kind friend, I feel deeply grateful to you. I am trying earnestly to accept your admonitions in the same spirit which prompted them, and I trust I have profited by them. You have given to my few poor words a prominence that I did not contemplate; but I hope your Christian effort has reached other hearts as well as my own. I have received many expressions of the deepest feeling from friends. I know they are friends, for no other motive could induce these offers to me in this obscure corner; but I know that only those whose experiences are similar to my own can fully understand my case. Well, it is from this class notably that these expressions come, and I should find much

encouragement in the fact that, in many instances, their heart-wringing sorrows have been exchanged for rejoicing.

As these kind words come from all over this broad Christian land, it would be impossible to reply in severalty, so I must beg a little space in GLEANINGS, because this must have been the medium through which they learned my address, and I can only say to each and all of them, "May God reward you as he only can!"

It is a sad comment upon the gratitude, or, rather, ingratitude, of the human heart, to say that immunity from suffering, uninterrupted sunshine, never brings us to our senses or to our Savior; that, while we are sailing over summer seas, we forget to prepare for disaster, but so I have found it. Friend R., your imaginary picture of my once joyous but now poor broken home, is singularly truthful; and equally true is your remark, that few words oftentimes express a great deal. When the heart is sinking down, down, down, a great wave of despair rolling over us, the weight of a dark world crushing us yet lower down, then the agonized spirit finds little use for words. But few words are required to tell that hearts have bled—that joy is dead, that hope has fled, that all seems starless night. Our parent hive is queenless now; the flow of our earthly sweetness has for ever ceased; but we have the hope, and we cling to the promise, that we shall begin anew where the flowers shall never wither, and where the flow shall continue throughout the long summer of eternity. G. C. STOKELY.

Arnoldville, Ind. T., May 24, 1887.

Friend S., I have often thought of the very point you make, that when we have uninterrupted sunshine and blessings innumerable, instead of bringing our hearts to the Savior in praise and thanksgiving, it is quite apt to lead us to get cold and indifferent; and at such times nothing but great trials brings us back to the foot of the cross. May God be praised that you are indeed rooted and grounded on the rock Christ Jesus.

REPORTS DISCOURAGING.

"TEN LEFT TO TELL THE STORY;" HOW SHALL WE
REPOPULATE HIVES WHERE BEES HAVE
DIED THE PREVIOUS SEASON?

MISERY always likes company—not that I am glad J. F. Patton (see p. 406) had the misfortune to lose 18 out of 21 colonies last winter, but I was especially interested in his report in GLEANINGS, May 15. I packed 23 colonies in the fall, and there are only 10 left to tell the story. Some of those speak feebly, while the other 13 joined that "innumerable caravan," and have "gone where the woodbine twineth." Mr. P. will surely be awarded the "first premium," because of his happy way of accepting the inevitable, and we can not but admire his spirit of thankfulness for the remaining *three*. But I wonder if, after all, at times he doesn't have "rolled across his peaceful breast" just a shallow wave of blasted hopes.

Mr. Root, what is your opinion as to the best method for us of repopulating these deserted habitations—buying bees by the pound, frames of nuclei, or full colonies? In this vicinity this winter's

loss has been quite heavy, and is largely attributable to the long severe winter—the bees being unable to take sufficient flights, so they became uneasy and diseased. I know mine did not die of starvation, for they had an abundance of good stores. In pursuance of the above facts, is there any preventive, except emigration to some fairer clime?

MARCIA A. DOUGLAS.

Shoreham, Vt., May 28, 1887.

My good friend, circumstances have much to do in deciding the best way to stock your hives again with bees. If new swarms can be purchased cheaply near you, that will be, perhaps, the simplest way; and if you wish to have the Italians, purchase some Italian queens and then divide each swarm into three or four parts, giving to the queenless parts one of your Italian queens. If you have to send to a distance to buy the bees, one pound of bees, with a queen put in during the month of June, will usually make a good colony by fall.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

A CARPENTER DRONE-BEE.

I SEND you by to-day's mail one drone carpenter bee. I caught him while he was looking for a mate. The blossoms are out here, and now is the time they are mating. If he is alive when you receive him, you can handle him without fear of a sting. If the drone carpenter bee survives the winter, why will not the drone bumble-bee?

G. J. FLANSBURGH.

So. Bethlehem, N. Y., May 16, 1887.

We sent the letter to Prof. Cook, and he replies as below:

The bee is in truth the drone carpenter bee, or *Xylocopa Virginica*. That it should be around at this season, and should mate now, does indeed seem strange, and contrary to the habits and economy of its near congeners. It is true, however, that these bees are very different from other species of *Apidae*. They bore into solid wood (see Manual, page 28), and thus make a nest, where they are measurably well protected. Thus there would not seem to be the same necessity for them to come late in the season. They also hibernate, and so their living over the winter would not involve such consumption of food as would that of the honey-bee. The whole subject needs investigating.

A. J. COOK.

Agricultural College, Mich., May 23, 1887.

PUTTING FOUNDATION IN SECTIONS.

I take my one-piece sections and rip through the center with my buzz-saw what is to be the top when folded, ripping five or six at one time; then when folding I fold and fasten in place one-half of the slit top, and, after pinching the fdn. to this piece, I fold the other half down, which secures it so no bee can pull it down unless they bite it off. I can put in the fdn., when I am folding the sections, about as fast as I can fold them without. I have tried this way for two or three years, and do not find that it weakens them much.

J. L. HYDE.

Pomfret Landing, Ct., May 31, 1887.

Your plan of putting foundation into sec-

tions will work nicely, and, if I am correct, has been used by various ones. The same plan is employed by our English friends for fastening full sheets of foundation in the top-bar of brood-frames. There are one or two objections, however, which I would urge against this method. In the first place, it is not every one who has a buzz-saw. In the second place, it mutilates, not to say disfigures, the section. In the third place, I hardly think it is as good a plan as the method of fastening foundation to the top of the section by compression. This is done with the foundation-fasteners advertised for the purpose, any one of which will fasten the foundation neatly, quickly, and securely into the section, without the necessity of grooving the under part of the section, or sawing into it.

THE NEW JAPANESE BUCKWHEAT.

On the 18th of March you sent me a 5-cent packet of Japanese buckwheat. About the 15th of April I planted one-half the seed (I gave the other half to a brother bee-keeper) in a piece of ground, about 3 x 7 yards, in drills 15 inches apart. When 6 inches high I gave it a hoeing. It is now waving and bowing to the earth with maturing grain. This new grain I expect to return to the earth in about two weeks as a second crop. I think this variety of buckwheat will do well here in the South, as it seems to thrive here right along in dry weather—a thing silverhull fails to do. This latter neither produces grain nor nectar in time of drought.

Whitney, Ala.

A. P. STAIR.

Friend S., your postal card upset me entirely. Here I have been buying this buckwheat in ten-bushel lots at a time, and paying enormous prices for it, when I might just as well have had a crop maturing in ample time to sow again this season as well as not. It just makes me ashamed of myself to think of it. Here I have green-houses, hot-beds, cold-frames, nice ground, and every arrangement to forward the crop, and it never once entered my head that I could raise two crops in a season and then scatter the seed ever so much faster and ever so much more cheaply than I am now doing it. There is no use in crying over spilled milk. Our seed shall go into the ground at once, and we shall have a big crop for next year, even if we don't do any thing more. I have understood there was difficulty in getting buckwheat to fill out the heads properly during the hottest summer weather; but I think good cultivation would give a pretty fair crop, any way. While I write, we have silverhull that sowed itself, now in bloom, and it might just as well have been the Japanese.

HOW AN A B C SCHOLAR, AFTER TRANSFERRING, WAS REMINDED OF P. BENSON.

I had a colony of hybrids in an old-fashioned box gum. I bought two Simplicity hives of friend Jenkins, at Wetumpka, and one fine untested queen. I began the operation about 4 o'clock in the afternoon, and completed the job about 9 o'clock. When I got through I resembled P. Benson's picture in May 1st GLEANINGS. My face was swollen out of shape; I got stung all over—face, hands, arms, legs, and on my back. I got them all in the new hive, and then came the job of dividing. I resorted

to my A B C book for instruction, and then proceeded. I divided them all nicely, and introduced my new queen. I kept her caged about 36 hours, and released her. She was received nicely, but, lo! in about five days, to my great astonishment I found them all clustered on a peach-tree. On examination I found that the old colony had robbed them of all stores, and they were compelled to hunt a new lodging. I hived them in the same hive, and am feeding them regularly. The old colony is doing as finely as I ever saw. I put them on foundation, and in four days they had a full set of as nice white pretty comb as I ever looked at. There were 9 queen-cells built in the old hive when I took the old comb out. I put them back in frames. B. G. LUTTRELL.

Luttrell, Ala., May 16, 1887.

CATCHING THE QUEEN IN A PEET CAGE.

I was reading in the A B C book to-night how you catch and cage your queens. You say, pick them up with the thumb and fore-finger. Well, now, I will give my way. I remove the comb that contains the queen that I want to cage, then set it down where it is handy to get at. The cut where Ernest is introducing a queen with a Peet cage reminds me of it. With the smoker I drive most of the bees away from around the queen, then with the slide partly drawn I set it gently over her. She leaves the combs and goes on the screen wire, and also the few bees around her. Generally I get enough bees in that way to send with her; then gently push in the slide, and queen and bees are caged without touching a bee with your finger.

MY REPORT FOR 1886 AND '87.

In the spring of 1886 I commenced with 13 stocks, and increased to 37. I bought two and lost one queenless one, so I had 38 to commence this spring with. They gave me 500 lbs. of honey, 400 lbs. of comb, and 100 lbs. of extracted. I wintered in chaff hives. I have built a bee-cellar to winter my increase in. W. D. SOPER.

Jackson, Mich., June 3, 1887.

DO BEES STORE WATER IN COMBS FOR WINTER USE?

About two weeks ago we took a colony of hybrids out of a tree. They had two large combs filled with water. There must have been a gallon and a half of water in the two combs. I suppose they stored the water in the winter time, while it was handy, as the nearest water in the summer time is about one mile away. Bees haven't done very well this season. So far it has been too wet. My first swarm came out the first of March. I took 30 lbs. of manzanita honey from a colony of Italians the 15th of March, and to-day I was looking at it and found every pound of it candied. My black bees get about enough from manzanita to live on, while the Italians are storing it by the pound. S. L. WATKINS.

Placerville, Cal., May 22, 1887.

Friend W., if it were not for the fact that you do not have rain in May in California, I should say the water you found in those combs was surely rain water that had got in by some means; but even this explanation would be a little improbable, for it is quite a difficult feat, as many of the friends may have discovered, to get water into the cells of a comb. I know that bees carry water in large quantities, but I have never been able to find more than a few cells full at a time in a bee-hive. They seem to use it up about

as fast as it is carried in. I can not for a moment believe they had struck on a plan of storing water in winter to last all summer; for even if they had sufficient ingenuity, the water would very soon evaporate and be gone, unless it were capped in the way that honey is capped.

ITALIANS THE BEST BEES.

My bees at this date were never in better condition. They have lots of brood, and are strong in bees. The drones have flown since May 1st. I never saw drones so early in the season. With me the Italians are the most profitable bees. They work the earliest in the morning, and quit the latest at night. They "hold the fort" against robber bees, and they are moth-proof. I had a colony reduced to a mere handful. They guarded the entrance better against robbers than a whole swarm of blacks.

Douglas, Q.

FRED LEININGER.

Your experience, friend L., seems to be the general verdict in regard to the justly praised Italians.

A FRIENDLY LETTER.

I feel as if I were somewhat acquainted with you, having read your A B C so much. Two or three years ago a friend of mine "went into bees" and had your book. I had no bees, nor did I expect to have then, though I wished to; but I borrowed the book, and read it with a great deal of interest. Last year I bought my friend's bees and the book. My daughter was reading it the other day, and she remarked, "If ever I go traveling, I am going to see A. I. Root." My Ernest, 11 years old, is very much interested in your account of your 14-year-old Ernest hiving the bees. Now he is married, as I see in the A. B. J. I also saw his name as president of a bee-convention. Blue Eyes is a big girl now — may be grown. Mrs. M. E. BROWN.

Athens, Clarke Co., Ga., April 14, 1887.

HONEY SEASON ENDED IN SOUTH CAROLINA.

I have had some trouble by bees destroying cells given them, and Mr. Doolittle has done us a favor in devising "queen-cell protectors," and you have also added another favor, in my humble opinion, in manufacturing them so neatly. Our honey season closes with the end of May; in fact, the most of it is over now. It has been a good honey year, despite the dry weather we have had until a week ago, and the high winds through the whole of April and the first week in May. My hives are all full of nice honey, but I could have doubled the quantity if I could only have given them attention; but I have been unable to do so, in consequence of sickness. My colonies will average about 50 lbs. of surplus. For ten days we have had some of the most beautiful weather possible anywhere in the world, which is saying a good deal, but not too much.

J. W. HUDSON, M. D.

Maysville, S. C., May 16, 1887.

A LETTER FROM NEW ZEALAND; FOUL BROOD THERE.

I have not done much with the bees yet. Last summer they had the swarming fever, and my spare time was taken up in making single Langstroth hives. They have not done yet, although we are within two months of midwinter. There was a small swarm yesterday. We are having splendid weather. Few places in the world can equal our climate. I increased from 6 colonies to 40. I took

only about 200 lbs. of honey. Next summer I hope to make something out of them, although the price of honey is very low—from 8 to 12 cts. per lb. We shall have to find a market in England. There is a large quantity of honey taken out of hollow trees in the forests. One consolation with us is, that the bees winter on their summer stands. I should like, though, if I had the time and means to put the hives in rows and put up a roof and board up the back. We are kept pretty busy with our cheese and butter farming, so I can not give that attention to bees I should like. I am sorry to hear you have had foul brood in your apiary. I hope by this time you have got rid of it. We are not free from it in this country. A neighbor, 8 miles off, has it among his bees very badly.

CHARLES DAVY.

Waugachu, Wauganni, N. Z., Apr. 18, 1887.

A LETTER FROM QUEENSLAND, AUSTRALIA.

The price of honey has gone down half this last eighteen months, with no sign of rising any more. The price now by the bulk is 2 pence, or 4 cents. The business is going ahead so fast that many are starting in it. I have made a solar wax-extractor after J. A. Green's pattern. It works well. I read, some time ago, in GLEANINGS, about some stingless bees. We have two sorts here, of no value as honey-producers; but I have taken as much as 3 quarts from a nest. All their comb is made of propolis, except the brood-nest. The brood is in its own cocoon, with no outer covering. S. W. Morrison, M. D., on page 15, Jan. 1, 1886, refers to a so-called discovery of a new use for honey, made by Dr. Comi, of Rome. In Book I. of "The Wars of the Jews," Chapter IX., by Flavius Josephus, written in the first century, he speaks of Aristobulus being preserved above ground in honey.

I think the worst thing we have to deal with here is excessive swarming. Mrs. Chaddock is put out with it in America. In Queensland they swarm from the first of September till the end of March, with very little honey after the middle of November.

I agree with Mr. Hutchinson on giving our new swarms starters only, as I tried it this season, and shall never give full sheets or combs any more.

ARTHUR BENSLEY.

Rosewood Gate, Qu., Aus., March 28, 1887.

A VISIT TO A BEE-KEEPER.

I was recently across the country some miles to visit a bee-keeper by the name of Johnson. He has about 200 colonies. He winters them in a cellar made especially for his bees. Among other ingenious devices he has a smoker. It is simply enormous—more than four times as large as mine, and of a peculiar construction, based upon a principle which seems to me to be good. He says it will not go out in a whole day, and is always ready for "biz" or buzz. Two years ago he threw away separators and burned over a thousand old-style sections. He has an odd section, $4\frac{1}{2} \times 5 \times 1\frac{1}{2}$, with open sides, or bee-spaces, all around. He says that these open-side sections are just as good in every way as the separator; and that, out of 8000 lbs. last season, he did not have fifty sections but that were first class. He makes his own foundation, and during the winter he makes his own hives. He also crates all of his sections, and has them ready by spring. His hives are all covered with clapboards nailed to narrow strips. He says this is better than dense shade. His crates are old style, and hold 30 sections, and constitute a part of the hive. He has a shop, tool-

house, and other buildings, to store away all of his traps; yes, and a honey-house, and racks on which to hang his frames of comb.

J. W. C. GRAY.

Monticello, Ill., May 30, 1887.

PUTTING GLASS IN FRONT OF THE ENTRANCE TO STOP ROBBERING.

I bought a colony of hybrids the first of May. They have worked well. May 30th I found that the neighboring bees were robbing mine. I threw a wet sheet over the hive, then consulted GLEANINGS that a neighbor had lent me. I followed the suggestion of putting a pane of glass before the entrance. They seem very quiet now. I do not know how long to leave the glass on. It seems to worry the bees. I think I shall enjoy taking care of my bees when I understand better how to do it.

MRS. G. N. HARMON.

Lawrenceville, N. Y., June 1, 1887.

Glass, in some respects, works very nicely; but one objection to it is, that it is apt to worry the inmates of the hive as well as the robbers. It should not be left before the entrance more than an hour or so. A better way is to contract the entrance so that not more than one or two bees can get out at a time. If you have a bee-tent, and they are robbing badly, place the tent over the robbed colony.

THE BEE-KEEPER'S HAT.

The bee-keeper's hat came to hand in good shape. It is a novel proceeding, to get a full-grown hat out of an envelope that cost only two cents for carriage. I improved mine by making a band of light zinc and attaching four small wires, which adds nothing perceptible to the weight, but holds the crown tight like a miniature tent.

A. A. PARSONS.

Avon, Ind., May 30, 1887.

Yes, it is a little strange that we can get a full-grown hat into a small envelope. In order that our readers may get the full force of friend P.'s remarks, I will say that the brim is four inches wide, and the whole hat fifteen in diameter. By a sort of sleight-of-hand movement it is folded so that it can be gotten into an envelope. It is slipped snugly into one not so very much larger than the common size used in correspondence. When the envelope is received, open and proceed to draw out the hat, and when about two-thirds of the way, you will be surprised to see it flop into shape. It is true, its weight is insignificant; and as a hat for holding out a bee-veil, I can scarcely imagine any thing more perfect.

FULL SHEETS OF FOUNDATION VS. STARTERS.

Will you kindly state, through your valuable paper, what are the reasons for using full sheets of foundation in the brood-nest, instead of starters only?

A BEGINNER.

Ohio, Ill., May 31, 1887.

By the use of full sheets of foundation in the brood-nest we can secure perfect combs, and we can also oblige the bees to build all worker comb or all drone comb, as circumstances in either case may demand. By the non or limited use of foundation in the brood-nest, you are subject more or less to the season and the inclination of the bees. As a rule, without full sheets of foundation we can not secure nice, perfect, well-filled

combs. Combs built by the bees are, many of them, imperfect, sometimes built on one side of the comb-guide, sometimes bulging clear out on one side, many times a good deal of drone comb when we want only worker comb. Where one desires to run for extracted honey, full sheets of foundation are a great saving. As a general rule, a beginner can not well dispense with full sheets of foundation; but I believe that one who has read W. Z. Hutchinson's book, experimenting carefully on a small scale at first, will be able to dispense with full sheets of foundation in the brood-nest, to considerable advantage, *providing* he is running for *comb* honey.

BEES DYING AT THE ENTRANCE.

One hive of my bees died at the entrance in the same manner as some one reported their bees doing some time ago, and I think you said that they were poisoned. Almost any time of day you can see, on the entrance-board, bees dying, shaking first, then before they die they behave as if some other bee had stung them. I thought at first that some one had been poisoning canker-worms with Paris green when the apple-trees were in bloom, but they behave the same now after the blossoms have gone. If they are not poisoned, and I think they are not, what is it? Can it be because they can not get water or salt enough? or do they get too much salt or potash, as some bees are for ever getting water out of the mud where we throw the slops? J. L. HYDE.

Pomfret Landing, Conn., May 30, 1887.

From your description of the way the bees act, dying at the entrances, I am strongly inclined to think you have what is called the "nameless" bee-disease. The symptoms are a sort of quivering and twitching motion. The abdomen is swollen, and the bee looks decidedly as if he were really sick. They will crawl out at the entrance and creep into the grass, as if desirous of the greatest good to the greatest number by riding the colony of their miserable presence. If you pinch the abdomen of the affected bee, a brownish substance will burst forth. This peculiar disease affects the bees alike in warm and in cold weather. The cure is, to destroy the queen and give the colony a new one. This treatment has scarcely ever failed. You suggest that your bees may have been poisoned. As a rule, I think it is always best to account for troubles of this nature from other sources.

WHAT AILS THAT COLONY?

My bees seem to have a strange way of doing business. They will swarm out, and almost invariably pitch for another hive. What is the cause? They have plenty of honey. I have had 25 swarms up to date, and will begin extracting in a few days. I have already taken some comb honey. I never lost a colony in wintering, and never fed five pounds of sugar. J. H. BURRAGE.

China Grove, N. C., May 6, 1887.

Friend B., it is hard to see why your bees swarm out as you describe, more than that it is a sort of mania that sometimes gets possession of apiaries in the spring. It usually takes place when there are a good many weak colonies. If you never had any loss in

wintering, however, I should suppose your colonies were strong. Probably the first swarm of the season went through with the maneuver you describe, and the rest followed suit, like a flock of sheep. I do not know that it has ever been explained, why a swarm of bees is quite sure to cluster in the same spot one that came out the day before did. In our back volumes a good deal has been said on this matter.

SLANDEROUS STATEMENTS IN REGARD TO THE REV. L. L. LANGSTROTH.

Was there ever any patent on the Langstroth hive? If so, who was the patentee? Some parties say it was patented about 1866, by Gould, or a name similar to that. It always ran in my mind that Rev. L. L. Langstroth was the inventor of that hive. Will you please give a full statement of this? These parties claim that Rev. Mr. Langstroth was a swindler, and was intruding on Mr. Gould's rights. This fellow says he has a book of this man's writings, and will show it to me. If this is truth, I was badly deceived. C. F. UHL.

Millersburg, O., May 23, 1887.

Why, friend Uhl, the whole matter is utterly ridiculous. Mr. Langstroth is better known in regard to bee culture than perhaps any other one man in the world; and whoever knows any thing about him knows him to be one of the kindest, fairest, and most honorable men who have ever blessed this fair earth. The man Gould has been as notorious for his evil deeds as Mr. Langstroth has been for his good ones. We have published this Gould as a swindler and scoundrel almost ever since GLEANINGS had an existence. He was formerly connected with what they called the "Common-sense" beehive. Such men are not worth listening to.

WHY DOES HONEY SUGAR IN EARLY SUMMER?

Can you tell why honey sometimes sugars at this season of the year? It is really hard to tell when it begins to sugar; but when once begun it seems that every cell that has honey in it is more or less affected, and will not extract. The honey does not seem to sugar as in the winter, but is more like mush-sugar. I have had it sugar once or twice in spring since I have been keeping bees. What is the best way to work it? Have you had any experience with it? The weather is dry and warm. I think the atmosphere in some way influences it.

Cornaca, S. C., May 24, 1887.

J. D. FOOSHE.

Friend F., this matter of the granulation of honey in the combs so as to resemble sugar is something hard to explain. A good deal has been written on it, but it seems it is honey from some particular source that behaves itself in this manner. I do not know that there is any remedy but to get rid of it as best we can.

SCREEN-DOORS FOR HONEY-HOUSES; WINTER LOSSES.

On p. 384 is a screen-door illustrated. My advice is (and I know whereof I speak), not to have any screen-door, but have a screen-window on the opposite side of the honey-house from the door, with exit-tubes in for the few bees, which are carried in on the combs for extracting, to escape. I have had the screen-door covered with robbers when I had to open it to enter the house; but after changing the

screen to the back side of the house, I had no trouble in opening the door, as the bees go to the side, where they come out to get a second load. This is safe advice, but you had better follow the advice of somebody else about wintering, for I undertook to control the temperature of my cellar with stoves and fire. Out of 225 hives I now have 25 queens with a handful of bees each, left.

We have met with a great loss in the death of our little boy, nine months old, after five weeks of sickness. The little fellow had just learned to say "papa" and "mamma," and was the pet of father, mother, brother and sister, and, in fact, the whole household of the Windham Hotel. I hope his death will prove to be a strong cord to draw us nearer to the place where we trust he is now, enjoying more than earth could have given him. O. R. COE.

Windham, N. Y., May 20, 1887.

Friend C., you have our sympathy in your great affliction; but we rejoice to know your hopes are anchored on the solid Rock.—Your testimony in regard to warming up cellars by artificial heat is truly a pretty strong one against it.

DOES HONEY FROM HONEY-DEW IMPROVE BY AGE?

Some time last year a friend gave me a 10-lb. can of honey, gathered from honey-dew the year previous. He called it "bug-juice," and said I could feed it to the bees. It had the color and taste of honey from honey-dew. This honey was kept during the winter in a cool dry cellar, and candied. In April I reduced it for bee-feed, and on opening the can I was surprised to see it look so nice. I put some of it on the table on the sly, with a good article of white-clover honey, requesting the family and boarders to give their opinion on the two articles. They were equally divided, one-half preferring the "bug-juice." To the party that gave me the honey, I sent a 3-qt. Mason jar of it, as something new, and they pronounced it excellent.

Bloomington, Ill., May 27, 1887. J. L. WOLCOTT.

I have never heard that honey-dew honey improved in the way you mention, friend W., and I hardly see how it could happen, unless the honey was in an open vessel, so the water could evaporate, and make it of heavier body. I am, however, aware of this: That very poor honey will granulate; but if you then slowly drain the liquid portion from the granulated part, and afterward melt the comparatively dry residue, you will have a very much superior article of honey. The item following illustrates this very fact of which I have been speaking:

SOUR HONEY IMPROVING.

I wrote you some time since in regard to a lot of honey, received of Westcott & Hall. Well, the honey was badly soured; but since the weather is cooler, it has granulated, and after skimming off the thin soured portion on top, the lower portion is very good clover honey. Now, Mr. Root, I am better pleased than I was; but I do not wonder that extracted honey is cheap when such sour, thin stuff as this is put on the market, and offered for sale to people who think all honey on the market is "made" honey (I did not question the purity of the honey). I thought I owed Messrs. W. & H. this explanation to you. It may be this is an average lot of honey on the St. Louis market; if so, the wonder is that it sells at all. S. S. LAWING,

Henderson, Mo., Nov. 22, 1886.

Every boy or girl, under 15 years of age, who writes a letter for this department, CONTAINING SOME VALUABLE FACT, NOT GENERALLY KNOWN, ON BEES OR OTHER MATTERS, will receive one of David Cook's excellent five-cent Sunday-school books. Many of these books contain the same matter that you find in Sunday-school books costing from \$1.00 to \$1.50. If you have had one or more books, give us the names that we may not send the same twice. We have now in stock six different books, as follows; viz.: Sheer Off, Silver Keys; The Giant-Killer; or, The Roby Family, Rescued from Egypt, Pilgrim's Progress, and Ten Nights in a Bar-Room. We have also Our Homes, Part I., and Our Homes, Part II. Besides the above books, you may have a photograph of our old house apiary, and a photograph of our own apiary, both taken a great many years ago. In the former is a picture of Novice, Blue Eyes, and Caddy, and a glimpse of Ernest. We have also some pretty little colored pictures of birds, fruits, flowers, etc., suitable for framing. You can have your choice of any one of the above pictures or books for every letter that gives us some valuable piece of information.

CONDUCTED BY ERNEST R. ROOT.

JIMMY AND SAM INVESTIGATING.

THE reader will remember that we left Jimmy and Sam in the back yard discussing how they could find out who had been stoning their windmill the night previous. They immediately set to work to repair the damages, as they desired to get it done before the school-bell rang for the morning. They gathered together the portions of the mill that had been broken off. With hammer and wire nails they soon had the windmill reconstructed, and even the boys themselves were surprised to see how quickly they made the repairs.

"After all," said Sam, "the damage is not so great as we had at first supposed, is it, Jimmy?"

"No," said the latter; "and I don't believe that anybody would ever know that any thing had ever happened to the thing." They then hastened to school, for they had not a minute to spare. At recess they noticed that Jake seemed more sullen and reticent than usual. Heretofore he had been accustomed to mingle with the boys in their general talk, but to-day he and two or three of his companions were off by themselves. Jimmy and Sam immediately found Frank, a boon companion of theirs, and one to whom they intended to communicate the facts. As the three boys stepped to one side, Frank exclaimed at once, "You have struck upon the identical fellow."

"Hush!" said Jimmy; "don't talk so loud; we want to keep kind o' still like, and not let the rest of the fellows know that any thing unusual is up."

"That's so," said Frank. "Come, let's us three walk down the street a piece, and I will tell what Jake did for me last night—at least, I feel pretty sure it was Jake who did it."

"Why, have you been building a windmill?" said Sam.

"Oh, no!" replied the other; "but I had a mighty nice patch of watermelons in my back yard. I planted them and tended

them all myself, and I'll bet a dollar that you couldn't find a better patch than these anywhere. Well, they were just growing nice," continued Frank, as the other boys started on, listening in silence. "I also had a patch of mushmelons right near by. I watched them day by day. Three or four days ago I was looking at the patch, and I found one great big melon that I said to myself would be ripe in a little while, for I had been thumping it every once in a little while, to see whether it was fit to pull. Well, this morning, when I went out to pick it, the melon was gone. Then there were two or three of my mushmelons that were not ripe yet, and these were likewise missing. Then the scamp, whoever he was, not contented with that, had gone and plugged half the other melons. Of course, they were not ripe, and now they will rot on my hands. I tell you, I *was mad*. My mouth was all ready for a good watermelon, and I knew it would be nice, crisp, and cool."

"So you think it was Jake, do you?" said Sam.

"That is just what I think," said Frank. "It was either Jake or one of his old chums."

"What makes you think it was Jake?" said Jimmy.

"Why, the other day I saw him looking over on that patch."

"What are you going to do about it, anyhow?" said Sam.

"I will tell you," said Frank, looking all around cautiously, to see if anybody was within hearing; "you know Jake lives neighbor to me. Well, he and the rest of his click are going to have a rooster-fight in his barn to-night after school. I got an inkling from one of the boys, who told me about it. I will manage to get home somehow from school before any one else, and then I will secrete myself somewhere around the barn, so I can see all that is going on, and hear what Jake and his click have to say about their rampage last night. They must have been on a regular tear, for I have heard enough to satisfy me; and when I have a nice opportunity to slip away, I will meet you two boys at your workshop, and report."

"Won't that be fun?" said the two boys. "We will know for sure to-night, won't we?"

At this juncture the school-bell rang; and as the boys were at a considerable distance from school they had to run in order to get there in time. After school was out, Frank gave a knowing wink to Sam and Jimmy, and then proceeded around by the back way. When out of sight of the school-children, he started off on an easy run. He soon got down to Jake's father's barn, and hastily slipped himself down between the hay and the side of one of the stables. After working and twisting he finally got himself so that his eyes were just on a level with a crack. He discovered the two coops with the game roosters in, and with which Jake and his companions were going to have their cruel sport. He did not have to wait long before he heard swearing and coarse

talk. Jake led the way. "Come on, boys!" said he; "see what I've got here."

Frank, in his hidden retreat, immediately recognized some of his own property, but he kept quiet.

"My! where did you get that melon?" remarked one of Jake's companions.

"Hush! don't talk so loud; don't you know nothin'?"

"My! that's a fine one," continued his companion; "say! where did ye get it?"

"Why, last night me and Jack stole over to Frank's back yard, and we just very naturally laid hands on these things. Don't you ever tell, now."

"No, I won't if you give me a good big slice out of it."

"Now, if you will keep quiet," Jake continued, "I will tell you something else. After I got these melons last night I thought it would be mighty nice to take the conceit out of Jimmy and Sam; so about ten o'clock last night I went to Mr. Green's. On my way I picked up by the creek some pretty good-sized stones—some as big as your fist. These I hurled with all my might at the windmill, and if I didn't make things rattle! I expected the boys would be awful mad this morning, but for some reason or nuther nothin' seems to have happened."

Jake's companions munched away at the melon, and complimented him on his boldness. After the crowd had finished eating their stolen fruit they commenced their cruel fun of rooster-fighting, and took out some old dirty pipes and proceeded to smoke. This was not at all pleasant for Frank, brought up, as he had been, unaccustomed to such doings; and just as soon as a favorable opportunity presented he slipped up on to the haymow and jumped out of the door on the opposite side of the barn, and got home without any one knowing that his eyes and ears had taken in the situation. After supper that evening he hurried up to the bee-hive factory, where he found the two proprietors anxiously waiting. Frank then related the whole conversation which he heard in his hiding-place.

"I just knew it was Jake," said Jimmy, after Frank had finished his story; "but now we know for sure. I tell you, I will give it to Jake to-morrow; if he doesn't go home with some black eyes, I am mistaken."

"Yes," said Sam; "and if his crowd back him up, we two will set in."

"Well, well, well," said Mr. Green, as his head popped up suddenly from the barn stairway into the workshop; "are you having a council of war?"

To tell the truth, the boys would rather have seen some one else at just this moment. The latter, having now and then caught a word sufficient to make him believe something was brewing, had cautiously slipped up the stairway and heard the boys' conversation.

"Now, boys," said Mr. Green, "I fully understand your situation. I have seen a great deal more of the world than any of you. I understand that you are going to have revenge on the one who has been giv-

ing vent to his spite in the way he did last night. If I were you I would let this matter drop. If you now take revenge upon Jake, there will not only be one set of bad boys, but two sets of bad boys."

"Well," said Frank, "Jimmy and Sam have fixed the windmill as good as it ever was; but how about my melons? Am I going to let Jake and his crowd repeat the same operation again, and let them think I don't know who did it?"

"Your situation is a little peculiar, that is so. Well, I don't know but that you ought to tell him that you know that he stole those melons. Give him just enough facts to convince him that you know all about it, and he will think that one of the boys told on him. You can then advise him not to repeat it, or you will be obliged to do something besides merely notifying him. One thing more," continued Mr. Green. "I see you have been fostering a desire for revenge; and as a means to this end you are going to employ the method used by bad boys—that is, give blow for blow. Boys, there is nothing noble or manly about fighting; there is nothing in it that commands the praise or admiration of the better class of society. I hope, therefore, that, so far as possible, you will try to get that noble revenge upon your enemy."

"What do you mean by 'noble revenge'?" said Jimmy.

"I mean, do good to them that hate you," said Mr. Green.

Frank and Sam were ready to admit that Mr. G. was right; but Jimmy declared that it would make him "feel real good to black Jake's eye;" but still, he agreed to do nothing very serious, providing Jake would let him alone.

To be continued July 15.

JUVENILE LETTER-BOX.

"A chiel's amang ye takin' notes;
An' faith, he'll prent it."

THE TRUMPET FLOWER.

My pa had 61 colonies last fall, but lost 3 in wintering. He intends to start another apiary this spring, and my sister Katie, age 18, is to take care of them. We live close to town, and can sell all the honey that we can raise. Pa will sow $1\frac{1}{2}$ bushels of alsike clover this spring. Do you know that the trumpet flower yields honey? We have a vine, or bush, in our yard; and last summer, when it was in bloom, we could shake half a teaspoonful of honey out of a single flower. It is easy to raise, very pretty, and blooms a long time.

JENNIE REPGLOE.

Centerville, Appanoose Co., Ia.

You say the trumpet flower had half a teaspoonful in each blossom, but you don't say whether the bees were able to get it or not—how is it, my friend? Of course, they would have to take quite a number of trips to and from the hive to carry half a teaspoonful of honey. The trumpet flower has been mentioned as a honey-plant in our back numbers.

FIFTY YOUNG QUEENS KILLED.

I have two hives, all my own; but I had bad luck with them. My pretty queen got killed when papa united them. Another young queen hatched which killed 50 queens that must have hatched with her. I found them in front of the hive, dead. The colony is doing very well now, and papa has very fine bees.
Atlanta, Ga. MARY HANBURY.

Your statement is quite an astonishing one, friend Mary. I have known a great many young queens to hatch out and be killed by a royal sister, but I do not think I ever knew as many as fifty from one hive.

PAINTING HIVES DARK.

I have one swarm of bees. Last summer it was so warm that the honey melted; and when it began to melt, the bees began to run out of the hive. It was like so much molasses and wheat all mixed up. I should like to come and see Mr. Root's bee-yard. More than that, I should like to see how he has his bees arranged.
Willie Carl.

Roaring Branch, Pa.

I fear, friend Willie, your hives must be painted some dark color, and left in the sun. A hive that is painted white will never, so far as my experience goes, melt down combs; that is, where the entrance is large enough, and unobstructed. If the bees get fastened in the hives in hot weather, they will create such a heat as to melt down the combs in any hive. Wiring the combs as we do, to keep them from being broken down, helps them to stand a moderate degree of heat.

A BOY'S EXPERIENCE IN HIVING SWARMS.

I will tell you how I got my bees. My eldest brother came home one evening last summer, and told my pa there was a swarm of bees hanging on a fence, a mile away. It was too late that evening to go after them, but early the next morning we went there and found the bees. Before sunrise we had them at home and hived. Pa said I might have them. They wintered well. Last summer I got 48 lbs. of honey, which I sold. I got a little more per lb. than pa did. My bees did not swarm last summer, and so I have only one swarm yet. It is a good one. Last summer I hived three swarms in one afternoon, all myself. They were large swarms. I got stung sometimes, but it does not swell on me. I guess I am too solid. I am 11 years old, and I weigh 120 lbs. We all like GLEANINGS very well. Pa had 62 swarms in the beginning of winter, and lost two so far. I am bound to be a bee-keeper, if I can make it win.

J. WARREN ROUTZON.

Findlay, O., Mar. 21, 1887.

SPEED IN PUTTING TOGETHER SECTIONS.

I tried my hand at putting up sections the other day. The first hour I put up 306; the second hour, 408. I think I did pretty well. The sections were those that pa got of you.

ALFRED HIGBEE.

Elsie, Mich., May 26, 1887.

If you will turn to p. 505, June 15, 1886, you will see that your record is slightly ahead of that of Pearl and Nettie Cranston, who previously have had the best record. You folded 408 in 60 minutes, which would be $6\frac{1}{2}$ in one minute. Nettie and Pearl each folded 500 in 75 minutes, which is just $6\frac{2}{3}$

per minute. So far as I know, your record is ahead of any other in putting together the *one-piece* sections. Still, however, your record as compared with that of Pearl and Nettie is so nearly equal that perhaps we had better say they are practically the same. Who can beat 408 per hour? To the first girl or boy who can equal 500 in one hour at a stretch, we will send any thing that may be selected from the ten-cent counter. Try again, friend Alfred. Perhaps in the third or fourth hour you may be able to win the present. Let us hear from you, little folks.

BROTHER WALTER'S BEES.

My eldest brother, Walter, who is 18 years old, has 70 hives of bees, part in Simplicity and American hives. He has two smokers, one Clark's cold blast and the other a Quinby. He has his bees in two apiaries, one at home and the other at Linn Grove, four miles off, where there are plenty of linn-trees. The bees are building queen-cells, and fixing to swarm. They are gathering lots of pollen from cottonwood, willow, dogwood, and sassafras. Bees commenced gathering pollen the 22d of January, from elm. Walter has traded his Novice honey-extractor for A. J. King's, made to take any size of frames. Honey sells at 10 cents per lb., and wax at 17 cents. There are not many people who keep bees around here. ROSALIE E. SOMERFORD.

Navasota, Texas, March 11, 1887.

WHAT BECAME OF P. BENSON AFTER HE SAWED OFF THAT LIMB?

Papa has bees, and I help him some. Last week a swarm came out and settled on a limb of a tall oak, near the top. Papa took a hoop off a nail-keg, sewed a sack around it, and fastened it to a long lath. He got under them on a limb, held it under the swarm, and rubbed it until the most of the bees fell into the sack, when he brought them down and hived them. Thomas has three calves. What do you think he has named them? P. Benson, Amos, and Huber. What became of P. Benson when he sawed the limb off between him and the tree?

ELLIE C. SMYLYE, age 8.

Caseyville, Miss., May, 1887.

Thank you, friend Ellie. Your father's arrangement for taking down swarms is almost exactly the same as that given in the A B C book, under the head of "Swarming." It answers very nicely, and has the advantage that it is light, and easy to hold out under the swarm.—I feel quite sure that P. Benson, "Amos," and Huber, will be not a little pleased to know that three *calves* have been named after them.—What became of P. Benson after he sawed that limb off, as shown on page 126? I am sorry to say he has never yet told us. Our artist took the picture of him when he was up in the tree, but was in such a hurry to get away (before the bees alighted) that he did not take time to wait for a second view—that is, of P. Benson, his swarm, limb, saw, and all, after they had settled on the ground.

DOES THE DIRECTION OF THE ENTRANCE HAVE ANY THING TO DO WITH ROBBING?

I am a bee-keeper and have good and bad bees—I mean those that sting. Bees have done well here. Some of our colonics face to the south and some to the east. This makes a difference, and papa says

that was the cause that two colonies got robbed. When we found it out the hives were full of bees, but all the stores were gone. Papa closed both hives for two weeks, and fed them; after that time one hive had brood in all stages, but the other one was queenless.

SOPHIE LOHE.

Island Station, Col.

I can hardly think, friend Sophie, that the mere direction in which the entrance may be pointing had any thing to do with the robbing you speak of. The entrances of several hives may be similarly situated, and be so near alike that bees will often become confused; but I hardly see how it could result in robbing. I am rather inclined to believe that the robbing of the two colonies was due to some other reason. If the bees are Italians, and the colony strong, with a good queen, and the entrances of moderate size, you need not fear that other bees will rob that colony.

WINTER LOSSES, REPORTED BY A LITTLE GIRL.

Papa had 20 swarms of bees last fall. He packed 18 of them in chaff and 2 in sawdust. He lost the two latter, and one that was fed late in the fall, and from which the chaff cushions were left off. The rest are gathering honey and pollen. People around here have not been very successful in wintering their bees. Mr. P. had 103 swarms, and lost about 70; Mr. A. had 19, and lost 1; Mr. W. had several swarms, and lost them all; Mr. F. and Mr. D. also lost all of theirs; Mr. S. had 4 swarms, chaff packed, and they all wintered nicely. One of papa's best swarms used to come out in all sorts of weather last winter. Once it came out when it was snowing, and at another time when it was only 5° above zero. We have 176 chickens, but the hawks carry some off every day. CLARA LINDSEY, age 11.

Harford, Susq. Co., Pa., May 7, 1887.

Friend Clara, I took your letter out first from among all the rest, because the writing is so clear and nice. It is really a pleasure to read the little letters that are written in a plain hand. It is true, you little folks do a great deal better than the big folks, as a rule; but still there is a chance, I think, for a great improvement in writing.—You have given us quite a little item in regard to the winter packing of bees. Your report would seem to indicate that sawdust is not always reliable for wintering bees.—The colony which you say flew out so much during unseasonable weather, I should judge had dysentery, so that they were uneasy.

A REPORT FROM LOOKOUT MOUNTAIN; INSECTS EATING BEES.

We take GLEANINGS, and like it very much. We have a small apiary. Bees have just begun to swarm. They are all pure Italians. There have not been many flowers for them to work on until lately, when the white clover came in. The red clover covers some fields, but I have not seen a single bee working on it. The azelias are in bloom, and the chestnut will soon be. The bees have been gathering honey-dew from the chestnut leaves. Until lately the bees would go down into the valley, load themselves, and fly up again. By the time they reached the top they would be so out of breath that they alighted on the edge of the precipices, and just panted. There is a rock on this mountain in Chicamauga Cliff, called Bee-Rock. In it lived about

a dozen swarms of bees. I think they must have been a swarm that had run away and settled there, and increased. There are a good many bee-trees on the mountain. Almost all of these bees are Italians. A large insect like a bumble-bee is the only enemy the bees have here. I saw one catching a bee. I caught it and put it under a glass with several bees, and it caught one, and then, seeing another trying to get out, it caught and held it while it was eating the other one. It makes a small hole in the bee's body, and sucks the inside out, leaving only the empty shell.

GEORGE LAWSON, age 13.

Lookout Mountain, Tenn.

Why, George, why don't you go and investigate that bee-rock, and find out what there is in it?—The insect you mention, is the *Asilus Missouriensis*, which has been frequently described in our text-books and journals.

WHAT TO DO WITH A FERTILE-WORKER COLONY.

My bees are all doing well now, except one colony which had two fertile workers but no queen. I killed the fertile workers, and am going to give them a queen-cell. They had queen-cells started.

In one of the hives where the drones were, the queen had quit laying, and looked slim, as if for flight. I think they will swarm soon. On the 17th of Feb., 1887, we had a hard wind storm that upset part of the hives. Some of the bees lay on the ground till the third day, and then the sun shone and warmed them up and they came to life and crawled into a hive. The thermometer registered 10 degrees above zero at 8 o'clock on the morning of the second day after the blow, and had been lower in the night, so you see bees are not always dead when you know they are.

I received the book you sent me for my letter, and was very much pleased with it. I am one year and one month over fifteen to-day, so I send five cents to pay for it. I don't believe in begging, anyhow.

CHARLIE STEWART.

Altona, Col., May, 1887.

Very good, friend Charlie; but I do not believe I am quite prepared to accept your statement, that bees are not always dead when you know they are. If the bees you mention lay on the ground three days while the thermometer registered as low as 10 above zero, it is certainly ahead of anything in all my experience in this matter; in fact, I do not think I ever knew bees to come to life after they had lain dormant from cold for as long a period as 3 days. If you caught and killed the fertile workers, you have done something more than most veteran bee-keepers can do. Are you *sure* that you killed the identical fertile workers? As a general thing, we can not distinguish them from any other bees, unless we can see them in the act of laying eggs in the cell. Putting a queen-cell into a fertile-worker colony might or might not cause the bees to raise a good laying queen. About the only sure way is to scatter the brood into several good colonies. I would give the fertile workers several frames of good brood and young hatching bees. You can then give them a queen-cell, or introduce a queen, and yet be tolerably sure that every thing will be well.

TOBACCO COLUMN.

TOBACCO, AND ITS EVIL EFFECTS. GOOD ADVICE FOR THE BOYS, FROM ONE OF THE MEDICAL PROFESSION.

FRIEND ROOT: I know there is more rejoicing over one sinner that repenteth, etc., but I'm weak in mental lore, and have much faith in an ounce of prevention. You will mistrust, by the dubious atmosphere about my person, that I am a "pill-peddler" by profession; but what has that to do with tobacco? Well, I want it to furnish a little weight to my testimony, and I want you to listen to me just the same as if I had been your old and respected family doctor for the last forty years, and had twice saved your great-grandmother from having the smallpox. But, to the point: I have seen many of the *evil* effects of tobacco, but never have seen any *good* to come of it. I will give some of its bad effects, as I have witnessed them: Palpitation of the heart is one of the most common; dizziness, weakness, trembling, and nervousness. I have seen some very severe cases of dyspepsia brought on by the use of tobacco, which were incurable until tobacco was discontinued. But the most deplorable effects which have been lately investigated by some of the ablest minds of the present age is over the mental faculties of the young. I am sure there is not a boy or young man, no matter how much he may boast of his superior qualifications of worthlessness or of evil doings, but that wants to be considered bright and intelligent. Here is just where the greatest evil of tobacco lies; and, what is more deplorable, that evil is latent. If it were rapid in its effects—if, I say, it knocked all the understanding out of a full grown boy in just thirteen minutes, and made him speechless until after he had taken a cold shower bath, it would be a very successful persuader; but, unfortunately, its action is slow. Its poison gradually steals a permanent position in the economy. It slowly but surely produces a sense of dullness, a languor, an indisposition in the mental faculties of a growing brain, a certain absent-mindedness, inability to remember proper names, dates, and time. The reason for this is because it retards nutrition by interfering with digestion, and its direct sedative action on the brain prevents normal action.

Of the different modes of using tobacco, chewing is the most objectionable, because more enters the system. Cigar smoking comes next; and the least objectionable is a clean clay pipe. But it makes me nervous to think of a compromise. I would by all means insist upon an "unconditional surrender."

Young man, if your mind is not fully matured; if you are not 25 or 30 years old, or if you have not yet taken possession of all the knowledge you care to possess, or if you don't want to forget all you have learned; if you want to be considered bright, active, quick-witted, and the equal or superior of your associates in mental discipline; if you want to be in good health, and have a sweet breath and a clean heart, stop the use of tobacco; for, I repeat, it can do you no possible good, and may prove to make your life most wretched.

I am sorry to say I was once a tobacco-user myself; but after seeing so much of the evil effects of it, I have wisely concluded to stop—the smartest thing I was ever known to do in my life.

M. R. NICHOLS, M. D.

I have quit the use of tobacco. I have used it since I was 12 years old, but I never intend to use it again; and if you think I am entitled to a smoker, send it; and if I ever use tobacco again I will send you the price of the smoker. M. N. SNIDER.

Lafayette, Lafayette Co., La., Apr. 15, 1887.

I have used tobacco for about 20 years, but have given it up as a filthy habit. If your offer is open for this year, and you think I am entitled to a smoker, I shall be very thankful for it, and I promise to pay for it if I ever use tobacco again.

Peterboro, N. H., May 2, 1887. G. W. GILMORE.

I have never used tobacco except in smoking, to which I have been quite a slave for a number of years. I will say, if you send me one of your smokers I will quit the use of the weed; and I promise, if I ever take up the habit again, to pay you for it.

Salineville, O., Apr. 25, 1887. J. W. MANNING.

Accept my thanks for the promptness of GLEANINGS, and for its teachings, for it has taught me the evil of tobacco, and encouraged me to quit its use. I have quit for good; and if I am entitled to a smoker, please send it; and if I ever use the weed again I will pay for the smoker. D. D. SLATER.

Blackville, Barnwell Co., S. C., Mar. 30, 1887.

I am one of your boys who will never use tobacco. I always used it to smoke the bees out of the boxes, but will never use tobacco again. I would never have started to using the weed if it had not been for my bees. If I ever commence the use of tobacco again I will pay you double for the smoker.

Wall Rose, Pa., Apr. 30, 1887. CHARLIE HERR.

I am very much pleased with the way you handle the tobacco question in GLEANINGS. I am one who has reformed. I used it for 13 years, and quit about 5 years ago. I have become more and more set against it every year, and I fully believe the day will come when it will be looked on and dealt with the same as whisky. S. H. BEAVER.

Tamora, Neb., Apr. 30, 1887.

I have given up the use of tobacco, and should like you to send me a smoker. I don't want to be paid for doing right, for I am now 2d vice-president of a missionary society, and expect to do right; but I want to know that I shall have a smoker to pay for if I break said pledge. It will always remind me of my promise. R. S. PARHAM, JR.

Stinson, Ga., April 19, 1887.

HEALTH IS BETTER.

I have quit the use of tobacco; and if you will send me a smoker, and I commence using the weed again, I will pay you full value for the smoker. My health is better than it was when I used the weed. I am interested in the bee-business. Our bees are doing as well as could be expected at this time of year. C. P. HUTCHINS.

Massena, St. Law. Co., N. Y., May 4, 1887.

By request of two of my neighbors who have decided to lay aside the expensive and filthy habit of using tobacco, I ask a smoker sent them, if you think them entitled or worthy. Please direct to A. Spraggin, De Soto, Floyd Co., Ga., and J. F. Long, Coosa, Floyd Co., Ga., and the smokers will be thankfully received. The parties promise to pay you if they should be so unfortunate as to return to tobacco. D. B. BRYAN.

De Soto, Floyd Co., Ga., May 5, 1887.

A PROMISE FROM A WOMAN.

I like GLEANINGS very much, and intend subscribing for it. I am just beginning with bees this spring, and wish to learn all the improved methods of handling them. If you will send me a smoker I will never use tobacco again in any form. If I should break my promise my husband would be sure to let you know it, and pay you for the smoker, for he is very much opposed to my using tobacco.

MRS. LILLIE CHARROCK.

Rising Fawn, Dade Co., Ga., May 4, 1887.

WHY WILL YOUNG MEN NOT TAKE WARNING?

Please send J. J. Gilbert a smoker. He quit the use of tobacco the 14th of Dec., 1886. He commenced using it when he was ten years old, and is now fifty. If he commences to chew or smoke again he agrees to pay one dollar for the smoker. I know of five old men in this neighborhood who have quit in the last six or seven years. Why is it that the young will not take warning? May God bless you in your efforts to do good. H. FREED.

New Stark, Hancock Co., O., Apr. 27, 1887.

NERVES AFFECTED.

I got neighbor Beckwith's GLEANINGS, and in perusing it I saw that you were giving all those who would quit the use of tobacco a smoker. I have quit the use of the vile weed. As to chewing tobacco, I never expect to do it any more, whether I get a smoker or not, and if ever you hear of my using it I will give you ten times the worth of the smoker. I would advise everybody to quit. I chewed until every nerve in me was affected, so that when I laid down at night I would jerk all over. Smithville, Tenn., May 2, 1887. A. B. CHEATHAM.

THE ALABASTER BOX OF HUMAN SYMPATHY.

There came unto him a woman having an alabaster box of very precious ointment, and poured it on his head, as he sat at meat.—MATT. 26:7.

Our alabaster box of love
And tenderness kept sealed
Until by death friends are removed,
These sorrows won't be healed,
But if, while they have ears to hear,
We often then may save
From many a pang and briny tear,
Too late when in the grave.
The kind things that you mean to say,
And acts you mean to do,
Say now before they're gone away,
And do before they go.
The flowers you mean to send their bier,
In life on them bestow;
They will appreciate them here,
But can not when they go.
Christ's followers called it heterodox
When Mary, with good sense,
Poured out her alabaster box.
Though worth three hundred pence.
If friends have boxes laid away
To break upon my head,
I'd have them broke while here I stay,
And not when I am dead.
I'd rather they would bring them out,
Or strew my path with flowers
While I'm beset with fears and doubts,
In these my weary hours.
I'd rather have a coffin plain,
Without a eulogy,
Than life without the sweets and gain
Of love and sympathy.
Let's learn to anoint our dearest friends
Before their burial day;
Post-mortem kindness does not tend
To cheer the spirit's way.
The fragrance of the flowers may last,
Fragrance on coffins may;
But never can it backward cast
Over the weary way.
To all who cease to smoke, still make
A gift to smoke the bee-sucks;
And thus continue still to break
Your alabaster box.

H. L.

OUR HOMES.

Thou shalt have no other gods before me.—
Ex. 20:3.

MY wife reminds me that she fears I am getting to write the same thing over to you in these Home Papers; to which charge I plead guilty, but offer, as a reason, that God's truths need repeating over and over again. As for myself, I have great cause to feel that I need line upon line, precept upon precept; and sometimes I feel almost discouraged to think I have to go over the same ground again, and fight the same battles over again, that I have been fighting in the Christian warfare for these years that are past. As I grow older, temptations of a different character present themselves to me, to some extent; but at the same time it is the old, old story—the conflict with sin—with inborn sin—with sins that are possessed in every human heart; and one of my greatest conflicts just now is to hold fast to that first and greatest commandment at the head of our talk to-day—"Thou shalt have no other gods before me." I used to laugh at the idea of the heathen bowing down to images of wood and stone; but now I feel more like bowing my head in shame and sorrow, because, as it often seems to me, I am but little better than they; and considering the light that surrounds us now, and the opportunities that were before them in those dark ages, I do not know but I need more of Christ's grace than they did. What did God mean when he gave this as the first and greatest commandment? Jesus makes the matter plainer, especially to us of the present day, when he says:

Thou shalt love the Lord thy God with all thy heart, and with all thy soul, and with all thy mind.—MATTHEW 22:37.

He further adds: "This is the first and great commandment." The reason why this is the first and great commandment is, that it covers all the rest substantially. The man who loves God, loves his fellow-man; and the man who loves his fellow-man as himself, will surely be in no danger of wronging his fellow-man, for he will take more pleasure in seeing him happy than in being happy himself.

This truth, like other scriptural truths, seems easy and simple enough in the abstract. We may hear it from the pulpit, and may nod our heads approvingly, and we may lament that all mankind do not see it as we do; but, alas! alas! when it comes to putting it into practice in every-day life, the depravity and deceitfulness of the human heart become painfully apparent. My friends, I do not feel like speaking of the sins of others when I take up this text to-day, therefore I want to say, when I start out to live this text, and try to make God's righteousness foremost, it is with great sadness that I contemplate the depravity of my own heart. At every turn I see selfishness taking the place of God. I see all sorts of things belonging to this world threatening to take the place in which God alone

should stand. In my plans for giving employment to my fellow-men, wherein I have found so much enjoyment, even there I find plans creeping in for my own up-building—for my own—shall I say my own honor and glory? I have been fondly thinking for some years past, that I had got over all ambitious plans and feelings; I have been fondly hoping I was truly content to labor and to put self aside—keeping out of the way or out of sight as far as possible—not caring to be mentioned; not caring for praise, but preferring, rather, in the language of the closing words of the Lord's prayer, "*Thine* is the kingdom, and the power, and the glory for ever."

I know by past experience that there is no comfort nor real substantial satisfaction in the praise of the world; I know by past experience that there is no real enjoyment in anything the world has to offer, where I can not take God along with me; but for all that, there are continual longings—there is a continual grasping after things that I know are not wisest and best. These conflicts are out of sight of the world, or, at least, I take care that they do not result in open action, and yet the world judges pretty fairly after all. There is nothing so deceptive in this world as sin itself. I know by past experience there is no comfort or satisfaction in transgressing any of the ten commandments, even in thought. It was Jesus, remember, who suggested that we could transgress in thought if not in deed. I have tasted of the pleasures of a sense of God's love and of his approval. Then why should I for one instant contemplate swapping these for any thing that this world has to offer? I know by experience that David spoke the truth when he said, "If I cherish iniquity in my heart, God will not hear me;" yet for all that, almost day after day I voluntarily and of my own free will grieve the presence of the Holy Spirit, and drive it away. Why, oh why, should I do this? At such times it is a comfort to me to read the words of Paul—words which I feel sure were uttered under circumstances at least somewhat similar. Just think of saint Paul himself, who was more devoted to the kingdom of God and his righteousness than any man who lived before, perhaps, or since, saying of himself, "For the good that I would, I do not; but the evil which I would not, that I do." And further on he says, "Oh wretched man that I am! who shall deliver me from the body of this death?" Over and over again, of late, I have been off by myself, and breathed out this little verse, and somehow peace and quietness have always come from it afterward. Some invisible presence has seemed to say, "There, there, child, that is enough. Be careful to remember how weak and imperfect and erring you are. My grace is sufficient for thee." And then come the words of that wonderful little hymn,

Just as I am, without one plea,
But that thy blood was shed for me.

One of my great trials is to keep humble—to forbear using the authority which I might use if I choose. At the noon service some

time ago, I spoke to the hands, in a little talk, about authority. I told them that it was my prayer that I might be able to keep the authority that was invested in me, entirely out of sight. I told them I wanted to move around among them as a fellow-laborer, a companion, and a friend; that I prayed God I might be able to keep out of sight and out of mind the fact that I was employer, or "boss," as it is so often termed; and I asked them, too, that those who have charge of rooms, and those who have help employed under them, would try to do the same—try to so manage that it should never be necessary to say, in a peremptory way, "Do this," or, "Do that." It is an easy thing for me to speak to my boys out on the grounds, when I wish them to take up some other work, something in this way: "Boys, will you please let this drop that you are doing now, and come with me?" or, "I think, boys, I wouldn't do this work the way you are doing, but like this." Now, I know by experience how much better this way answers; and I know by experience that cases are very rare where one we employ disobeys, if we explain to him exactly what is wanted of him; but for all that, past experience seems to amount to nothing. All these years of practicing and experimenting and studying upon the way that God's commandments work in the hearts of men seem to count for nothing. Every few days I find myself away off the track—away out of the straight and narrow path. In place of the pleasant good-natured child of God who used to stand in my shoes (if you will pardon the expression), my better self has gone out, and a usurper has come in. A man stands there whom I shudder to think of or look at. He is selfish and cold and unfeeling, and domineering. He has no care nor respect for God nor for God's commands. His god is self, and he cares nothing for consequences. If you tell him a certain act is wicked, he says, "Who cares if it is? If you don't want to get hurt, get out of my way." His heart is in the right attitude to utter oaths and curses; he has no love for his fellow-man; he has no respect for—do you shudder, dear reader, at such a picture? and do you say that that is the effect of overwork and a disordered imagination? Alas! it is but too true; and those who have been striving to follow Christ may recognize the picture from its semblance to similar glimpses they may have had of their own hearts. Without the Savior's love—without the grace of God in my heart, I should have been a fearful specimen of humanity. I have sometimes looked in wonder upon the friends and neighbors about me. I have even looked upon unbelievers—those who have never made any profession whatever, and I have firmly decided that none of them have had even a glimpse of the way in which Satan has tried to get hold of me. I can not believe it possible that others have ever been tempted as I have been, and yet I do not know. Each heart has its own secrets, and only God knows how many a poor wretch has breathed the prayer, "God have mercy on me a sinner." I have sometimes wondered—yes, even lately I have wondered

whether the dear Savior had any place in heaven for such as I. I have wondered whether he could make any use of one whose heart has been so full of wicked thoughts and depravity, and yet I am not sure the fault is altogether mine, for I often think of the illustration in *Pilgrim's Progress*, where the evil one whispered evil suggestions over Christian's shoulder, and then persuaded him they came from his own heart. At such times I turn with wonderful comfort to the saying that Christ Jesus came into the world to save sinners. If being a sinner is one of the qualifications to entitle one to Christ's regard or love, surely he came to save me; and when I wonder if it be possible that such a heart as mine may be really and truly cleansed, and be made fit for the courts above, then I remember the text, "The blood of Jesus Christ cleanseth us from all sin." Jesus told Peter that Satan desired to sift him as wheat, and I have wondered whether Satan hadn't decided that his best time to open up on me with all his artillery was just about now, when I am getting to be nearly fifty years of age. May be he has been sifting me, and perhaps he will, after awhile, go away. But I do not want him to go and torment somebody else as he has tormented me; in fact, if I thought he had got to busy himself tormenting somebody, I think I would try to bear it; for I have Christ by my side to strengthen and comfort me, and some other poor soul may not have. There is a little verse in our hymns that reads:

Tempted and tried!
Oh, the terrible tide
May be raging and deep, may be wrathful and wide!
Yet its fury is vain,
For the Lord shall restrain,
And for ever and ever Jehovah shall reign.

There is one other thing I wish to speak of, and yet I dislike to, for the reason that only a part of the friends may understand me; but I will try to make it plain. Some of you may imagine that much property would make you happy; you may think that having money to buy whatever you may want would surely enable you to be peaceful and happy all the day long. Some of you may think, who have struggled long years with debt, that great happiness would surely be the result of having a balance ahead in the bank. Some of you have hard work to get along on your farms and keep things in order, as you would like to have them, and think it would add to your enjoyment of this world to have plenty of help to do every thing you feel you would like to do. Others may have thought that a successful man must certainly be a happy one—that one whose plans, inventions, and projects all turn out to be prosperous and successful would be the one who could give praise to God from the bottom of his heart, day after day. I want to tell you, my friends, that you are mistaken. It is true, that when we have worked hard for the accomplishment of some object, a sense of happiness and of God's approval comes to us after the toil and the hardship are over, providing, of course, the work be a praiseworthy one; but money of *itself* does not

bring happiness, neither does property, nor having plenty of help and plenty of money to pay your help promptly. On the contrary, these things bring trials that many know nothing of. I have sometimes thought Satan seemed to take it for granted that plenty of money would spoil the best Christian, and that his best chance was to lay siege to the Christian who had been prospered in this world's goods. Some of you may have thought it would be nice to have people to do your work for you. My friend, when you have once had the burden on your shoulders, of keeping one hundred or more men at work, and at work in a way that will be profitable to you and to themselves, you may change your mind about it. It may be nice and pleasant for a while; but when the novelty wears off, and when you find that you are harnessed up, and that your time is not your own, and that your brains, your muscles, and your surplus energy, are not your own, you may pine for freedom.

Now, I do not complain of my lot in life; I do not mean to complain of the work whereunto God has called me. At first thought I might say, if Satan would just let me alone, and take his fingers off from me entirely, then I should be satisfied; but if God has, in his infinite wisdom, seen fit to test and try me, perhaps in a very small measure as he did his servant Job, then I hope I am willing to say, "Amen; thy will, not mine, be done."

It may be a simple matter to some Christians to keep in heart as well as deed this first commandment—"Thou shalt have no other gods before me;" but it has not been by any means an easy task for me to keep this command as I think it ought to be kept. The question may be asked, "How shall we know when we are letting any of the things of this world get where they are in danger of coming before God?" My test is this: Whenever any thing takes so much of my thought and time that it seems to stand between me and God, I feel I am surely in danger of breaking the first commandment. Whenever you are so absorbed in business, pleasure, or in laying plans for this world, that you are forgetting your Maker, and seem to be getting away from him, then are you in danger. The sense of this danger seems to be more acute with me when the time comes for me to write these Home Papers. When the printers inform me that they are ready for Our Homes, then comes a test of my spirituality. If I have been getting off the track, my faith and love toward God seem to be dull and cold. At such times I often feel myself totally unfit for any such sacred office as ministering to those who are hungering for the bread of life; and woe betide me if any thing that has happened dims my sense of the presence of God's love in my heart. Sometimes these things that seem to come between my mental vision and God come in such strange and unexpected ways—in such guise, as it were, that I fail to detect the presence of Satan, until I begin to feel my spirituality gone. Sometimes a disposition takes hold of me to have my own way, no matter what may be

the consequences. Again, Satan whispers that I can not help myself; the tide of affairs is sweeping me along without my being to blame at all. At another time the things of this world that come between me and God's love seem to be too great for all my strength. Even going off by myself does not always seem to answer. They get between me and God, even while on bended knees. I will now tell you how I have triumphed over Satan in such cases.

You have perhaps noticed a child that had got his temper up, and it seemed almost impossible to conquer it. May be you have seen a boy in school who behaved as if he would die rather than give up; or two men engaged in a lawsuit. They seem determined to lose all the property they have, in a contest that is insignificant. Well, a good many times there is wisdom in *dodging* such issues. I think there is wisdom in the parent who evades the necessity of stirring up a child's stubbornness and evil temper; the same with the boy in school, and the same with a neighbor. May be you think it strange that I should talk about dodging Satan. Well, I have dodged him a good many times, and I will tell you how I do it. He plants himself right before me. If I stop and look at him, or argue the case, it seems as if he comes out best—at least I never get ahead of him in that way. If I go off by myself to pray, *if I don't look out* he is before me, even there. Now, then, *how* shall we dodge him? Why, my good friends, if you are ever in such a predicament, just use your plain common sense. Pick up a hoe and go out into the field and hoe potatoes until you are tired and hungry; or, better still, busy your mind and body in something that will do somebody some good, and *keep busy*.* Raise potatoes if nothing else offers. Put your heart and soul into it, and, before you know it, God's love will come into your heart again, and you will feel the approving voice, "Well done, thou good and faithful servant." To tell the truth, that is just where I stand this morning. I tried facing Satan, and did not make any headway. I left him, and, naturally enough, when I got busy with mind and body, in some *good* work, I had soon forgotten all about him, and was surprised when I discovered that he was gone. At such times a peace comes into my mind that I can not exactly describe. It is the peace that God gives to every one who has dropped and abandoned folly, and chosen wisdom—to one who, by his acts in life, as well as by words, has declared he has no other god in the wide universe than the one true God who created the heavens and the earth. To him he is loyal, honest, and true. In the Gospel Hymns is a verse composed from the text, "He said

* When Moody was in Cleveland some years ago, some leading skeptics and infidels wanted to discuss the matter with him. They challenged him to meet them and argue the case. He refused to argue or discuss with them. When somebody protested against such a course, and asked an explanation, he replied, "My friends, I have no time." And he was right. The man who is doing good to his fellow-men in the way that Moody was and is, *has* no time to discuss theology, and a great many times we waste our time, and get ourselves into trouble, by attempting to discuss or dally with Satan.

unto her, Thy sins are forgiven," as found in the seventh chapter of Luke. The last verse of the hymn describes the reward God gives to those who have put the world behind them, and who have triumphed over Satan, and stand before him true and loyal, with the first commandment given from Sinai. The verse is this:

In the sky, after tempest, as shineth the bow,—
In the glance of the sunbeam, as melteth the snow,
He looked on that lost one; "hersins were forgiven."
And the sinner went forth in the beauty of heav'n.

WINTERING BEES IN A CYCLONE- HOUSE.

A BEGINNER'S EXPERIENCE.

I PURCHASED 10 nucleus swarms from Oliver Foster, some hives from A. J. Root, and started in the bee-business. We had a very dry season—no rain for 3 months, from June 1st, but the bees managed to fill the brood-chamber all right, and made 200 lbs. in the section boxes. This I took for my share and gave them the rest. As soon as cold set in I carried them into a cyclone-house, built all under ground, with a roof of dirt four feet thick, with a stovepipe in the center, for a vent. The cave, or cellar, was very damp, so I screwed some narrow strips of board on the side of the hives, near the cover. The strips were six inches longer at each end than the hive, making the hives look something like a box for carrying coal in. Then I made racks along each side of the house and hung my bees up by the handles on their hives; but I first took them out of the portico hive and put them in the upper story so as to avoid a permanent bottom-board. I then made a bottom-board by putting on screen, such as we use on our doors, and in the same way, and hung it on the bottom of the hive with hooks, so the bees could not come out, but so one could take it off while they were asleep, turn it over, and hook it on again, or jar off any dead bees or any other litter, and give them plenty of air. After that I took some old newspapers and spread one of the four sheets over the hive, then put the cover on tight, letting the paper extend outside all around. Thus I shut off the air above, knowing that too much air might give them a sore throat. Then I thought if, after going to all that trouble, they wanted to die they would certainly be very ungrateful. But they did not die. I looked at them as often as once a month, and always found them dry, and clustering up next the paper, and all over the frames. However, I found considerable moisture in the top of the cover. This I threw off, generally, so I put a little block under the paper to raise it in the center and allow the moisture to run out under the cover, in case it fell back on the paper. Sometimes the little busybodies ate through the paper, in which case I just spread another over that one.

I carried them out as soon as maples blossomed, and put them into the porticos again. They had honey enough to have wintered again, so I let them keep it. Up to date two have cast off swarms, and all are doing as well as could be expected, since the drought is on us again, and on to stay, according to all appearances. The temperature of that cyclone-house ranged from 36 to 40°. Now you know how a greenhorn winters bees.

ED. PARKER.

Union, Iowa, May 23, 1887.

OUR OWN APIARY.

CONDUCTED BY ERNEST R. ROOT.

FOUL BROOD.

SINCE our last report, foul brood seems to have gotten under way in every portion of the home apiary. We have been treating sometimes as many as five or six colonies daily. To-day, June 10, the boys have found a dozen cases of foul brood, and this afternoon we are going to treat them—by complete extermination as at first? oh, no! We shall employ the starvation method, or perhaps, more exactly, a modification of it. As we have been experimenting upon the cases developed in the last few days, and have not as yet arrived at any definite conclusion, I will not give the exact *modus operandi*. Suffice it to say, we have now had 40 cases of foul brood in the last three or four weeks. But, more anon.

THE DOOLITTLE QUEEN-CELL PROTECTOR.

During this spring and summer we have been giving the Doolittle queen-cell protector a pretty thorough trial. All the cells we have raised this season were placed in the wire protectors before insertion in the hive; but for some reason or other we have not met with very good success. Mr. Spafford showed me some of the cells which had been gnawed into. Upon inquiry I found he had not pushed the apex of the cells into the apex of the wire cone, and the bees had, in consequence, crawled into the mouth of the protector, and so gained access to the sides of the cell. I then told Mr. S., hereafter to push the apex of the cell down in such a way as to close the mouth of the queen-cell protector. He then obtained somewhat better results. But even then cells would be found with the capping torn off, with the young queen within not fully mature.

I feel pretty sure that Mr. Doolittle obtains better results than we have so far. It is possible that the manner in which we construct the protectors makes a difference. We sent a sample to Mr. Doolittle when we first made them, and he pronounced them all right. Perhaps there is some trouble from the way in which we manipulate the cells in the hive. At any rate, we should be glad to be shown where the trouble lies.

CONSIGNMENT OF IMPORTED QUEENS; TWENTY-FIVE QUEENS RECEIVED,

AND NOT ONE DEAD.

Shortly after our last issue was out, we received a consignment of 25 imported queens from Italy. Upon opening the boxes we found that every queen was alive and hearty. Not only that, but the queens were unusually nice ones. I do not remember to have seen as nice a lot. One was sent off as soon as it arrived, and the remaining 24 were introduced successfully, as usual, in the

PEET CAGE.

If there is such a thing as "absolute and unvarying success" in bee culture, the Peet cage, in our own apiary, has come as near reaching this high standard as any thing we have ever tried. When we found that

all the imported queens were alive, I felt morally certain that every one of the said queens would be introduced successfully in the hives. We gave Neighbor H. ten to take to his apiary, sent one away, and the remaining 14 we introduced in the Swamp Apiary. Both the queens which Neighbor H. took, and those which we reserved, were introduced with entire success. In order to make room for some of the imported queens which we introduced we were obliged to cage the queens where we had just taken out a queen to fill an order. That is, we took the old queen out, and at the same operation caged an imported one in her place. In one or two cases the imported was out and laying in twelve hours from the time the former queen was removed.

After the 14 queens were all caged on the combs, I told the boys not to release them, and, as far as possible, to let them entirely alone; if, in opening a hive, they discovered that the queen seemed weakly, and liable not to live much longer in confinement (which I thought was hardly probable), they might then release her.

I believe a large part of the losses occurring from introducing by the Peet process is, that beginners become unduly anxious for the queen. If she is not out in 24 hours, they think they must release her. This fussing, opening the hive, and pulling off the cage, is liable to cause the bees to ball the queen. If the beginner let the Peet cage do the work itself, he will be vastly more sure of success, providing the cage has been placed over a few cells of honey, and on good old hard comb. I mentioned this fact in connection with the Peet cage, on page 1001, last year. Since that time two or three seem to rather doubt whether it were best to let the Peet cage shift for itself; but from almost constant experiments, year after year, I feel more satisfied than ever that it is far better to let the Peet cage do its work automatically. The two men we have in our apiary this season are beginners; but when they commenced work I gave them instructions something as above, on introducing queens. We introduced a large number of queens this spring, and, with the exception of one or two virgin queens they have not lost a single fertile queen. I have taken this occasion to reiterate these facts for the benefit of beginners, and to show how the best results may be obtained with the Peet cage.

THE HYDE APIARY.

Something over a week ago Mr. Spafford and I drove down to the Hyde apiary, put on the honey-boards, T supers, and, in fact, got every thing ready for a flow of comb honey. We aimed to put each colony, so far as possible, under different conditions, for the purpose of more accurately getting at results.

NO HONEY.

At the present writing, no honey has come in, and the bees have been for nearly a month on the point of starvation — barely sustaining themselves. If honey does not start pretty soon now, we shall not expect much from clover.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER,
MEDINA, OHIO.

TERMS: \$1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, JUNE 15, 1887.

Work out your own salvation with fear and trembling.—
PHIL. 2:12.

WANTED, GLEANINGS FOR MARCH 1, 1887.

If mailed us at once we will allow 10 cents each for the above.

THE WHITE-CLOVER CROP AT THE PRESENT WRITING.

THERE seems to be a general complaint, that, while the bloom is most bountiful, very little honey is coming in. We presume this is on account of much rain. At such times clover usually yields bountifully just before its close; in fact, a few reports already state that white-clover honey is coming in bountifully. Much rain usually, for the time being, spoils the honey-flow.

MR. THOMAS HORN.

OUR friends will remember that Mr. Horn said, on page 319:

I am preparing the notes just as rapidly as possible, and will finish this evening so as to go out in to-morrow's mail.
THOS. HORN.

And again on page 408:

FRIEND ROOT:—I mailed, as promised, all notes excepting a few retained for further investigation, which I have since mailed; and now to the best of my knowledge all have their notes. If I have overlooked any, if they will kindly inform me I will mail them at once.
THOMAS HORN.

Now, we think it best to be slow to condemn; but when we tell our readers that complaints have been coming continually during several weeks past, saying that Mr. Horn has as yet sent no note at all, we feel very much inclined to think the time has come when forbearance ceases to be a virtue. May 31st we wrote Mr. Horn, asking him for an explanation; but up to the time of going to press, no word has been received. I may mention, also, that I have been severely censured for accepting his advertisement again, even though he did promise to give notes to all his customers. Perhaps some of the sufferers may become impatient at our way of doing business, but we hope they will be patient a little longer. And now, friends, since we have heard of so many who have *not* got their notes, will all of those who have received them please inform us at once by postal? We want to know exactly how many have received Mr. Horn's note in the way of settlement. It seems very plain and certain that Mr. Horn can give his notes for the amounts he is owing, if he has any disposition to be fair and honest. However, we think it best to wait a little, as the case stands.

BEESWAX, AND HOW TO SEND IT TO MARKET.

IN years past I have repeatedly cautioned the friends about sending heavy shipments of beeswax by express, for the reason that the express charges are sometimes almost equal to the value of the wax.

One friend away down south actually sent several cakes of beeswax by mail. The postage on the wax was 16 cts. per lb., as everybody knows, and was worth, when it got here, 22 cts. per lb., and so all he got for his wax was 6 cts. Now, if you send wax by express, especially where you live away off, it is pretty much the same way. Better sell it near home for what it will bring you, or wait until you have 100 lbs. or more to ship by freight. In fact, I can not imagine any excuse for sending beeswax by express at all. If you say you are owing us, and are anxious to pay the account, please remember we are never in so much of a hurry that we want anybody to pay express charges on beeswax. A great many times several neighbors can club together and thus get a cheap freight shipment. Another thing: If you *must* send small lots of wax, don't, we beg of you, go and put it in a great heavy box, but simply tie it up in a bag. A good strong phosphate-bag that can be bought for five cents almost anywhere is just as good as any thing else, and then you have no express or freight charges to pay on a box that is of no use when it gets here. You may think we are taking a good deal of space for so simple a matter. Dear friends, little packages of wax, with large express or freight charges, are coming to us on almost every train, and I hope we are just as anxious to save you expense as we are to save our own money.

DELAYS ON ORDERS DURING THE PAST MONTH.

THE season just closed has been the heaviest in the way of business ever known at the Home of the Honey-Bees. Notwithstanding the new factory put up last summer and fall, which we hoped would enable us to meet any possible demand for sections and bee-hives, we have been perhaps as badly behind as we ever were before. We are, however, as we go to press, nearly caught up. The only department that has been inadequate is the wood-working establishment—especially in the matter of sections. Some of the friends who waited until the months of May and June, and then sent in orders for odd-sized goods, were obliged to wait, some of them, for as much as two or three weeks. The reason for this is, when we are running full blast, with every saw going, we can make three or four thousand regular-sized sections where we could make one that requires us to stop and readjust the machinery. Under such circumstances it does not seem fair to make the friends who order regular goods suffer for those who order something irregular. There may be some who feel hard because we have not filled orders in regular rotation. We have before explained the difficulty in doing this strictly. One of you may order something that we have an abundance of in stock, while your neighbors order the very thing we are out of and can not furnish; and as most of the orders are made up of a variety of goods, a great many times an order is already to ship, with the exception of one thing, and this may be the state of affairs for a week. Sometimes it will answer to send a part of the goods at one time, and the rest at some future time; but as this makes additional charges we dare not often do this, unless the order is a large one. We are making preparations now to make up a stock of goods this fall, in order that we may not be in the same predicament another season; but very likely the result is, we shall have a great many things to keep over. Styles may change, goods made up may be superseded by

something better; but there is no other way that I know of to prevent these very annoying and perplexing delays. Now, we distinctly state in our price list, page 3, that we can not be responsible for delays in orders sent in during April, May, and June. We should like, however, to have those who have suffered by our lack of promptness to state briefly what amount will make the damage satisfactory. We do not think we should stand *all* the loss you are out of pocket thereby, for an extensive bee-keeper who waits until May or June before sending in his orders to a supply-dealer is certainly at least partly to blame. We wish, however, to have every thing arranged pleasantly, so far as it is in our power, before commencing another season's business.

W. Z. HUTCHINSON,

ROGERSVILLE, GENESEE CO., MICH.,

HAS received scores of unsolicited testimonials in regard to the excellency of his little book—

"THE PRODUCTION OF COMB HONEY,"

and it is with pleasure that he publishes the following selections:

Success to the little book, fresh and live ideas.—E. E. Hasty, Richards, O., March 28, 1887.

It is the best book on the production of comb honey I ever read.—F. W. Holmes, Coopersville, Mich., March 29, 1887.

I congratulate you on getting up such a complete treatise upon the subject in so small a book.—W. H. Shirley, Mill Grove, Mich., March 27, 1887.

Your little work on "The Production of Comb Honey" is a valuable acquisition, and coincides with my experience.—Dr. L. C. Whiting, East Saginaw, Mich., April 23, 1887.

It is simply at the head, in every respect, so far as it goes. All can say that there are larger books—those that cover more ground, but *none* that cover their ground nearly as well.—James Heddon, Dowsagiac, Mich., April 2, 1887.

You have given us a valuable work. Though terse, it lacks nothing in completeness. We need more such books—those that give facts in the fewest words.—For four years I have practiced essentially the system you give, and know its superior worth.—Dr. G. L. Tinker, New Philadelphia, Ohio, April 17, 1887.

Your book received last night and read through before I could sleep. To be sure, I knew the most of it from your articles in the bee-papers, but it is nice to have it all together in a neat little book like yours. You just more than boiled it down, didn't you?—Dr. A. B. Mason, Auburndale, O., Mar. 29, 1887.

Friend H.: Have just received your little book. Much that it contains will be found new, I think, with the *majority*. The cost in production must in some way be lessened. You set out the primary elements by which such lessening of cost may be made. I say heartily that I think your little book should be studied carefully by every producer of comb honey. With kind regards—J. E. Pond, Foxboro, Mass., March 28, 1887.

Your lovely little book gave sister and me much pleasure, and the author will please accept many thanks. Since criticism is invited, permit me to say that we reach the conclusion *too soon*. Had the book been less interesting we might not have discovered the fault—might even have thought it a *merit*—but since the book is as good as it is pretty, its brevity is a serious fault; a fault which will surely be amended in the second edition.

With the hope that it may everywhere receive the cordial welcome that it merits, I am yours truly—"Cyula Linswik."

Price of the book, **25 cents**. Stamps taken; either U. S. or Canadian. 10tdfb

DADANT'S FOUNDATION FACTORY, WHOLESALE AND RETAIL. See advertisement in another column,

Wants or Exchange Department.

Notices will be inserted under this head at one-half our usual rates. All ads intended for this department must not exceed 5 lines, and you must say you want your ad in this department, or we will not be responsible for any error. You can have the notice as many lines as you please; but all over five lines will cost you according to our regular rates. Of course, this department is intended only for bona-fide exchanges.

WANTED.—To exchange for good horses and mules, 200 colonies of bees in Simplicity frames; also 40 acres of land adjoining the city. 20tfdb ANTHONY OPP, Helena, Phillips Co., Ark.

EGGS for hatching.—Wyandottes, Polands, Hamburgs, and Leghorns, in exchange for section boxes, or foundation. Circulars free. 4tfdb. A. H. DUFF, Creighton, Ohio.

WANTED.—To exchange Barnes foot-power saws and bees, for steam-engine, honey, or beeswax. 7-12db C. W. & A. H. K. BLOOD, Littleton, Mass.

WANTED.—To exchange English lop-ear rabbits, Guinea pigs, and water-spaniel dog pups for bees by the pound. F. GROSSMAN, 11tfdb Kamms, Cuyahoga Co., O.

WANTED.—To exchange 400 two-piece and 400 one-piece 5 $\frac{1}{4}$ x 6 $\frac{1}{4}$ V-groove secs., for 1000 4 $\frac{1}{4}$ x 4 $\frac{1}{4}$ Forncrook one-piece secs. (send sample); or for 5 purely mated Italian queens, daughters of imported mothers. J. M. YOUNG, Rock Bluffs, Neb. 11-12

WANTED.—To exchange my new catalogue of bees, queens, new section-case, for your address on a postal card. Address F. A. EATON, 11-12d Bluffton, Allen Co., O.

WANTED.—To exchange three city building lots, 25 x 102, in the city of St. Andrews Bay, Florida, for Italian bees, comb foundation, or any kind of apianian supplies. Titles to property are good. Address B. G. LUTTRELL, 12tfdb Luttrell, De Kalb Co., Ala.

WANTED.—An experienced apiarist wants permanent position, or to take off this season's honey crop. Southern States. H. HENRY, 12d Blandon, Pa.

WANTED.—To exchange Quinby hives and Simplicity one story, with 8 frames of drawn-out combs, for bees of any kind, or white paint. 12tfdb Mrs. OLIVER COLE, Sherburne, Chen. Co., N. Y.

WANTED.—To exchange a "Star" bicycle for bees. Just the horse for a bee-keeper. 1213d Box 375. C. H. SMITH, Pittsfield, Mass.

WANTED.—To exchange Italian and hybrid bees in Simplicity hives for a first-class 50-inch bicycle. D. S. BASSETT, 12tfdb Farnumville, Wor. Co., Mass.

WANTED.—To exchange 40 lots (7 acres), situated 4 miles north of State House at Indianapolis, for land south or west. Good house and other buildings; ground set in fruits. Will trade for improved farm or lands well located. 12d JOHN CADWALLADER, North Indianapolis, Ind.

WANTED.—To exchange 16 American hives with frames and old combs, hives in good order and newly painted, for 3 good Italian swarms. 12d J. FERRIS PATTON, 163d St. and Morris Ave., New York, N. Y.

ESTABLISHED 1855. BEESWAX HEADQUARTERS.

We have constantly on hand a large stock of Domestic and Imported Beeswax in original shape, which we offer to manufacturers of Comb Foundation at lowest prices. We guarantee all our beeswax absolutely pure. Write to us for prices. Address **R. ECKERMANN & WILL,** Beeswax Bleachers & Refiners, 4-12b SYRACUSE, N. Y.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough to these queens to pay for buying them up and keeping them in stock; and yet it is often times quite an accommodation to those who can not afford higher-priced ones.

In Italianizing I often have albino and Italian queens that are mismatched, which I will sell at 20 cts. each. Blacks at 12 cts. each, when I have them.

J. F. HIXON, Sir Johns Run, Morgan Co., W. Va.

I have 12 more hybrid queens which I will send by return mail at 30 cents each, or 4 for \$1.00. Safe arrival and satisfaction guaranteed.

G. D. BLACK, Brandon, Buchanan Co., Iowa.

I have 10 hybrid queens, ready by return mail at 35 cents each. Satisfaction guaranteed.

MARKWOOD JERVISS, Maumee, Lucas Co., O.

I will sell black queens for 25 cents and hybrids for 40 cents, by return mail. Wings clipped, and raised in 1886.

GEO. L. FERRIS,
Five Corners, Cay. Co., N. Y.

BLACK AND HYBRID QUEENS FOR SALE.—Black, 25 cents; hybrid, 40 cents; mismatched, 45 cents.

W. G. HAYEN, Pleasant Mound, Ill.

I will pay 25 cents for 25, 50, or 75 hybrid queens, if sent to me in small lots during this month and the early part of July.

O. R. COE,
Windham, Greene Co., N. Y.

J. P. MOORE

Makes a specialty of rearing **Fine Warranted Italian Queens** from his choice strains of Italians, which is the result of 7 years careful breeding. Send for circular telling how they are reared, and see what his customers say. Prices, warranted queens, each \$1.00; per $\frac{1}{2}$ doz., \$5.00. Safe arrival and perfect satisfaction guaranteed. Address **J. P. MOORE, Morgan, Pendleton, Co., Ky.**

100 5-FRAME HIVES OF ITALIAN bees with young queen in light boxes, \$4.00; 2-frame nuclei with young queen, \$2.00; same 3-frame, \$2.75. Untested queens, 75 cents. 11tfdb **L. HEINE, Bellmore, Queens Co., N. Y.**

\$3.50 per M. for sections with the V groove, and smooth both sides. 12d **E. S. MILLER, Dryden, Mich.**

Comb Foundation. 10 lbs. or more, 30 and 40 cts., to close out present stock. Samples free. 400 lbs. warranted selected yellow beeswax, 25 cts.; also from 300 to 500 1st class brood and upper-story combs. For price, state kind and number wanted. 12d **H. L. GRAHAM, Grandview, Ia.**

THE CHANCE OF A LIFETIME.

A good 2-frame nucleus and young warranted queen for **only \$2.50. Just think of it.** And more! All ordering during June will receive next spring a present of 2 doz. of Ohio and Souhegan raspberry plants. No circulars. Order from this adv't. Write you name, P. O., Express Office, and County and State of each plainly. Safe arrival guaranteed. Will begin shipping June 25. First come, first served. **S. A. Dyke, Pomeroy, O.**

BY SENDING 30 CENTS

in stamps, you will get by first mail a **HANDSOME BOX** of note paper and envelopes **FOR LADIES** and containing new put up specially **Pen and Pencil.**

Foundation-Mill For Sale.

We have on hand a 14-inch foundation-mill for making heavy foundation that was laid aside to give place to our power-mills. This mill is in excellent condition and makes very nice heavy brood foundation. The regular price of a 14-inch mill is \$40, but we will sell this for \$20.

A. I. ROOT, Medina, O.

A Barometer for Gardeners and Farmers.

We have finally succeeded in getting a wonderfully pretty little aneroid barometer that we can sell as low as \$2.50. One of them has been carefully tested by the side of our mercurial barometer, and it follows the rising and falling of the mercury with wonderful accuracy. It seems to me that these little instruments ought to pay for themselves over and over again for any farmer or gardener, or any person who is dependent on the vicissitudes of the weather. The instrument most resembles a pretty little clock, and it may be sent by mail safely for 10 cts. extra for postage. You will remember that my method of using any barometer is to pay little or no attention to where the indicator or mercury stands. When you wish to know what the weather will be, tap the instrument with the end of your finger. If the indicator (or mercury) falls, there is a prospect of rain; if it rises, you are pretty safe in deciding there will be no rain very soon. If a considerable storm is approaching, the mercury will keep falling for some hours, and it will drop a little every time you touch it, even though you tap it as often as once an hour. When it keeps dropping for several hours, look out for a storm or a big wind. If it keeps rising for several hours, go on with your work and you will very seldom be misled.

A. I. ROOT, Medina, O.

PURE ITALIAN QUEENS.

Tested queens, \$1.50 each; untested 75c. each; 3 for \$2.00. All bred from select imported mothers. By return mail, 100 2-frame nuclei with untested queen at \$2.00 each.

POTATO BOXES

(TERRY'S).

These are made of basswood, bound with galvanized iron. The galvanized iron gives strength, and the basswood strength and lightness. These hold exactly a bushel when level full, and may be piled one on top of another. Although they are made especially for potatoes, they can be used for fruit, vegetables, picking up stones on the farm, and a thousand other purposes. When piled one above the other, they protect the contents from the sun and rain; and from their shape a great many more bushels can be set into a wagon than where baskets are used. They are also much more substantial than baskets.

Price 25 c each; 10, \$2.25; 100, \$20.00. In the flat, including nails and galvanized iron, \$1.75 for 10; 100, \$16.50; 1000, \$150.

A. I. ROOT, Medina, O.

PASTEBOARD BOXES

FOR ONE-POUND SECTIONS OF

COMB HONEY.

This box has a bit of "red tape" attached to it to carry it by. It makes a safe package for a single section of honey for the consumer to carry, or it can be packed in a trunk, if he wants. It can be opened in an instant. The price of the box is 2 cts. each, set up; in the flat, 15 cts. for 10; package of 25, 30 cts.; \$1.00 per 100; or \$9.00 per 1000; 10,000, \$80. If wanted by mail, add \$1.00 per hundred for postage. Colored lithograph labels for putting on the sides, two kinds, one for each side, \$3.00 per 1000. A package of 25, labeled on both sides, as above, 50 cts. By mail, 30 cts. more. They can be sold, labeled on one side or both sides, of course. We have only one size in stock, for Simplicity sections. Sample by mail, with a label on each side, 5 cts. If you want them shipped in the flat, labels already pasted on, the price will be ten cents per hundred for putting them on.

Your name and address, and the kind of honey, may be printed on these labels, the same as other labels. The charge for so doing will be 30 cts. per 100; 250, 50 cts.; 500, 75 cts.; 1000, \$1.00.

A. I. ROOT, Medina, Ohio.

COMMON SENSE Automatic Door - Check.

SOMETHING THAT EVERY GOOD HOUSEWIFE
HAS BEEN LOOKING FOR.

Who has not felt the need of some simple and effective device for holding a door at any desired position? Many times you want to let in a very small amount of air, and it is difficult to fasten the door just where you want it. Many people use a couple of bricks, but these are unhandy, and ungainly looking things.

The accompanying cut shows the nicest thing for the purpose we have ever found. It is very simple, and yet very effective. It is attached to the corner of the door with four screws. You place your door just where you want it and press your toe on the upper end, pressing it hard against the floor. In the meantime the small dog catches it and holds it there and your door is securely fastened. When you want to release it to shut or open the door, simply touch your toe to the dog, and the spring inside presses the center bar up out of the way. The lower end has a rubber cap inserted so that it may be used on a carpeted floor, or even on a nice hard-finished floor, without injury.

If you try one you will want one for every door in your house. The price is only 35 cts.; by mail, postpaid, 45 cts.

Stanley's Special Offer for July.

**A \$20.00 Stanley Automatic Extractor
For Only \$16.00.**

To those who will agree to exhibit my extractors at fairs and conventions the coming fall I will sell, during the month of July, a Stanley Automatic Extractor to take four standard L. frames, and warranted perfect in every way, for only \$16.00. This machine sold last season for \$21.00, and the present season for \$20.00; but I make this liberal offer to those who are willing to assist in the sale of machine. Do not think that this is a reduction in price, but only a special offer for one month. Every machine is made with baskets large enough to take sections if need be, and all late improvements will be attached with no extra charge. You do not need a circular to order from as this advertisement is my warrantee of the machine. If you do not use the L. frame, I shall be pleased to quote you reduced prices on any odd size of frame for the above-named time.

Do not ask for time on a machine, but inclose \$16.00 and send along your order.

Remit by P. O. money order; exp. money order; reg. letter, or N. Y. draft. If you send local check, add 25c.

G. W. STANLEY, Wyoming, N. Y.

GIVEN AWAY.

We will send free by mail one of our latest improved drone and queen traps to each yearly subscriber for the **AMERICAN APICULTURIST**. Price \$1.00 per annum. Sample copies free. Send the \$1.00 in common letter at our risk.

G. W. GILLET, Wellington, Ohio.

W. Z. HUTCHINSON,

ROGERSVILLE, GENESEE CO., MICH.,

WOULD respectfully call the attention of all who use foundation, to the fact that he has written, published, and now offers for sale a neat little book of 45 pages, entitled

"THE PRODUCTION OF COMB HONEY,"

in which, among other things, is made as clear as possible the question of when, where, and how to use Foundation. When empty combs are preferable. When the bees should be allowed to build their own combs. How to prevent the building of drone-comb, etc., etc., etc.

The price of this book is only 25 cents, and the knowledge gained from its perusal will enable its possessor to save more than the price of the book, in foundation, upon each swarm hived; and secure more honey into the bargain. Don't wait until the swarming season is over, but send for the book NOW—and be ready to test, this season, the plans and methods it advises.

Stamps taken; either U. S. or Canadian.

Fine Italian Queens, reared from best selected, tested, imported mother, \$1.00 each. 10ftdb

You can not look over the back No's of GLEANINGS or any other Periodical with satisfaction, unless they are in some kind of a Binder. Who has not said—"Dear me, what a bother—I must have last month's Journal and it is nowhere to be found"? Put each No. in the Emerson Binder as soon as it comes, and you can sit down happy, any time you wish to find anything you may have previously seen, even though it were months ago.

Binders for GLEANINGS (will hold them for one year), gilt lettered, for 60 cts.; by mail, 12 cts. extra. Ten, \$5.00; 100, \$45.00. Table of prices of Binders for any Periodical, mailed on application. Send in your orders. **A. I. ROOT, Medina, Ohio.**

The Canadian P. O. authorities refuse to receive these through the mails, as they exceed the proper weight for merchandise.

tries of the Universal Postal Union, 18
cts. per year extra. To all countries
NOT of the U. P. U., 42 cts. per year extra.

PAINTING HIVES.

WHAT COLOR AND WHAT KIND OF PAINT SHALL
WE USE?

HAVING just finished painting a lot of bee-hives I thought a few words on the matter might be of interest to the readers of GLEANINGS. In days of box hives, arguments were used against painting hives, some of which were valid, and, to my knowledge, the painting of a hive which is closed bee-tight by wood, top and all, is a great disadvantage to the rapid breeding of bees in early spring. When I first began keeping bees I had six box hives, four of which were painted and two unpainted. I kept them three years, and the two unpainted ones always swarmed from a week to ten days in advance of the others. On all cool nights the moisture would come out at the entrance of the painted ones, so as to stand in drops of water in the morning; while the unpainted were as dry about the entrance as at mid-day. This caused me to decide against painting hives, so my first frame hives were not painted; but after I began to use bee-quilts, and chaff and sawdust cushions, I found that this did away with all the objections to paint, except its cost, for all the moisture arising from the bees readily passed off through the cushions, so the present finds me painting all of my hives.

WHY PAINT.

My reason for painting hives is, first, durability; and, secondly, looks. As to the looks part, no one, I think, will venture to say but that a well-painted hive is far more attractive to the eye than an unpainted one; but when it comes to durability, taken together with profitableness, some think it would be more profitable not to paint, and renew

the hive as often as is required. The reason for such a decision lies, I think, in the hives not being properly painted. Most of the painted hives which I have seen are not painted at the most essential points; namely, where the hive sits on the bottom-board, and where the cap, or cover, rests on the hives. All joints where the water can get in and find a lodging are the first places to decay, and need paint there much more than they do on the plain sides of the hive where the wet soon dries out. Properly painted, and kept so, a hive will last a lifetime.

WHAT COLOR TO PAINT.

After using nearly all colors on hives, I have come to the conclusion that white is the only satisfactory one to use, for two reasons; the first and greatest of which is, that the bees can be left standing in the sun the year round in hives so painted, and be comfortable, without the lifting and expense of shade-boards, with no danger of combs melting down; and, second, the right kind of white paint does not want renewing nearly so often by having the oil drawn out of it as do the colors. It is hard work to get any colored paint that will stay good over three years, while white lasts six, eight, and even ten years in very good condition. But for the overworked bee-keeper, the first is of the most importance. A man who can lift a 15 or 20 pound stone, a shade-board, and a cover, from each hive (replacing them in turn) all day, must have an iron constitution, and one which I believe could be more profitably employed, and might be, if, instead of thin boards, white paint were used.

WHAT PAINT TO USE.

Several years ago the editor of GLEANINGS recommended the Averill paint as the best for hives, while, if I am correct, he now recommends white

lead and oil as the best. Seeing his former recommendation I was induced to try the Averill, which gave good satisfaction, except that it sometimes cracked or peeled off. For a hard stonelike finish, to my mind no paint can equal the Averill outside white; but for sticking to a smooth surface, probably lead and linseed oil is equal to any thing, so for the past few years I have painted my hives by putting on two coats of lead and oil, and, after thoroughly dry, giving them a coat of Averill. This gives them a hard glassy finish, which will resist sun and rain for years, lasting fully twice as long as three coats of lead paint would do. How I came to use the Averill in this way was, that at one time I had to do with the property of others, the buildings of which had been painted every three years with lead and oil. This had so accumulated that the surface of the buildings was very rough; and the oil being driven out it washed with every driving rain so that the grass and ground would be white with lead. I thought to try Averill, giving only one coat, and the result was eight years of excellent service, and at the end of that time it was much better than the lead paint was after two years.

OBJECTIONS TO ALL WHITE.

The only objection to having the hives all of one color, and sitting in symmetrical shape, is the danger of bees mixing and of queens getting lost on returning from their wedding-flight. To overcome this I use a board in front of each hive, which answers the twofold purpose of keeping grass and weeds down, and by its position enables the bees of each hive to recognize their home. A day or two in the winter is pleasantly and profitably spent making (and cleating so they will not warp) these boards. If you wish them to look nice, paint them in colors.

G. M. DOOLITTLE.

Borodino, N. Y., June, 1887.

We have taken your article down to our painter. He agrees with you in the main in what you say, but says that he thinks the kind of paint we are now using, the lead and zinc, is equal to or better than two coats of white lead and the Averill over it. The Averill paint is going out of use almost altogether; whereas white lead, mixed with one-third zinc, is now in almost general use among painters. A few years ago, after discontinuing the use of the Averill, we came to the conclusion that white lead was the best; but our experience lately confirms us in saying that the addition of oxide of zinc makes the paint far more durable. It is with this that we are painting all our hives. It is possible, however, that two coats of white lead, covered with Averill paint, might be still more durable. Eight years of good service is about all we ought to expect; and I am not sure that the lead-and-zinc paint could equal it. We agree with you in what you say in regard to the use of white as a color. For many years we have had all our hives painted white, and we rarely have trouble with combs breaking down. In this connection, friend D., we should like to ask if painting the front of the hives in different colors makes any difference with the bees as to their ability to distinguish their own hive. We do know, that where the hives are all painted white, though similarly situated otherwise, causes more or less trouble from young queens get-

ting lost, and bees intermingling from one hive to another. We would refer you to what A. W. Osborn says in this connection, in another column.

DRAGON-FLIES OF THE SOUTH.

PROF. COOK ON THE DARNING-NEEDLE OF OUR CHILDHOOD DAYS.

THE large insects sent by Mr. W. J. Drumright, of Sarasota, Fla., of which he says, "These large mosquito-hawks came in such numbers as to nearly stop the bees from flying, just as the bloom was at its best. I send you two of the pests; can not you or Prof. Cook give us its name, history, and especially the duration of its winged state," are our largest dragon-flies, or darning-needles. In Europe such insects are called horse-stingers. Their scientific name is *Æshna heros*, Fab., or *Æ. constricta*, Say. They are too much broken to permit of identification. Surely they are objects of real beauty, as their shining green eyes, which form the major part of their big heads and the brilliant green stripes which mark the side of their thorax, can not but attract attention, and no one can fail to admire the graceful flight of these gems of the insect-world. These dragon-flies belong to the order *Neuroptera*, or nerve-winged insects, so named because of the intricate venation of their wings, making them to resemble lace, hence their common name as well, lace-wings.

All of these insects are predaceous—that is, they live upon other insects—and that in all stages; as larvæ, with no trace of wings; as pupæ, when the wings are short—mere pods—and as imago, when they are full fledged, and sexually perfect. While these large, active, four-winged insects are the terror of the insect-world, they are entirely harmless to higher animals; hence the English term of horse-stingers is entirely inappropriate; and the story which filled many of us American children with fear till we learned better, that these insects would, upon occasion, sew up our ears, is likewise entirely without foundation. These dragon-flies are really as harmless as a house-fly, and never harm any one. From their predaceous character these insects do very great good, as they destroy multitudes of our injurious insects. With the exception of two or three species of our largest ones, like *Æ. heros*, Fab.; *Æ. constricta*, Say., and *Anax junius*, Say., I have not any reports of any that destroy bees. Strangely enough, these species, though found all over our country, have been complained of only by Southern bee-keepers. I have heard of their doing quite serious mischief on different occasions in several of the Southern States. The larvæ are also very predaceous. They, however, live only in the water; and as they prey on aquatic insects they do us no harm. These larvæ are very curious in one or two respects. First, they have terrible jaws, which are masked by a dipper-like hinged kind of tongue. Thus they appear very harmless; but let a delicate mouthful in the shape of some water-maggot come along, and the mouth-cover is quickly unhinged and the morsel taken in. This curious mouth could not but interest any person who might take time to observe and study it. These larvæ are also peculiar in the position of their breathing-organs. These are in the rectum. Water is slowly drawn into this posterior end of the alimentary canal, which bathes

their gills, and thus furnishes the life-giving oxygen, and then is forced violently out, which sends the insect rapidly forward. Thus this arrangement serves both for respiration and locomotion.

The imago, or mature dragon-flies, live for weeks, and may be seen mating on the wing, and flying over water, depositing their eggs, either by gluing them to aquatic plants, or dropping them into the water.

There seems to be no way to protect against these savage marauders except to capture them by the use of a long-handled net. This has been practiced with considerable satisfaction in several Southern apiaries.

A. J. COOK.

Agricultural College, Mich., June 16, 1887.

DANIEL McFADDEN, AND HIS PLAN OF WINTERING BEES.

IS IT A HOAX?

FOR some weeks past I have been unable to give much attention to bee-literature. The death of a dear brother and sister, within less than a month of each other—the first break, so far as brothers and sisters are concerned, in a family circle of nine that has been unbroken for over sixty years, have been events that, with their attendant and consequent duties, have fully occupied both mind and time. On reading up the bee-journals awaiting perusal, I find, among other matters calculated to awaken the *cacoethes scribendi*, that extraordinary letter signed Daniel McFadden, which appeared in GLEANINGS for May 1. Not the letter itself merely, but the sub-heading and foot-note are extraordinary. The sub-heading announces, "W. F. Clarke's Hibernation Theory Established on a firm Basis." Now, I most emphatically demur to this. The letter does not affect my theory, or in any way whatever relate to it, nearly or remotely. It is hard for me not to think that, whoever prefixed that sub-heading, "A. I." or "E. R.," or somebody else about the office, must have known, quite as well as I do, that my theory is not involved in the absurd story about "wintering bees up toward the north pole without any stores whatever." It may have been meant as a joke at my expense, and GLEANINGS does appear to be getting somewhat jocose; witness the "P. Benson" letters; but I confess I do not like jokes that are cracked at the expense of truth and fact. Such jokes do harm. We have a conspicuous example of this in the Wiley joke about artificial comb manufacture. I have an abhorrence of lying, even in jest. What too many people are in the habit of calling "fooling" I honestly believe to be as truly telling lies as any other form of that crying and common sin.

But in view of the extraordinary foot-note, I am not sure that GLEANINGS regards the narrative as a hoax at all. It is discussed as though it were sober earnest, and matter of fact. I have read somewhere that the only way to get into a Scotchman's head the perception of a joke, is by the aid of a mallet and chisel; and I am inclined to think there are others besides Scotch people of whom that is true. You have written to George Watson; but although two issues of GLEANINGS have appeared since the McFadden letter was published, there appears to be no response. I doubt if there ever will be; and if there is, it is most likely it will come

from a fictitious party who is one of the ring of impostors which is trying to palm off a method of wintering on the bee-keeping public, which is "too-too" absurd and ridiculous for any thing.

I have never dreamed, and consequently never argued, that bees could be wintered in a "frozen stiff" condition, and "wholly without food." One of my articles on this subject was headed "Chilled Bees not Hibernating Bees," and I have invariably contended that bees, in order to sink into that state of repose which I believe to be essentially hibernation, must be in a temperature which makes them feel comfortable. Excess, either of cold or heat, breaks up the hibernating condition. The effect of extreme cold is first to rouse an abnormal activity, then to induce an enormous consumption of food, and finally to bring on diarrhea, which is fatal to the very existence of the colony.

A common mistake in discussing this matter is that of supposing that there is only one kind of hibernation. Of this, the bear is usually taken as the only admissible type or example. But the bear is not "frozen stiff;" and though he consumes no food in winter when in the hibernating state, there are stores of adipose matter packed away in his carcass, by drawing on which, life is sustained during his long sleep. Other hibernating creatures—squirrels for instance—do not sleep all winter long, but wake at intervals, take a good square meal, and then go to sleep again. We know that bees can not lay up stores of fat in their little bodies, like the bear, and that they must feed, at least semi-occasionally. In a thoroughly normal winter temperature, favorable to a snug and profound repose, bees consume very little honey; there is but slight waste of tissue, and they come out of winter quarters refreshed and rejuvenated by a long season of rest and quiet.

The foot-note says: "Bees have over and over again been wintered with so small an amount of stores, that more than one of the bee-friends have been almost persuaded that bees could live for months without any food at all; but yet all experiments made directly to prove this have somehow failed, and most of us have settled down to the belief with Professor Cook, that bees do not hibernate." There are some queer statements in this sentence, on which more light is needed. Who among the "bee-friends" ever became "almost persuaded" that "bees could live for months without any food at all"? I fail to recall one; but the foot-note asserts this of "more than one."

WM. F. CLARKE.

Guelph, Ont., Can., June 4, 1887.

My good friend Clarke, we may have been thoughtless, and we may have taken liberties in speaking of your hibernation theory. If so, we beg pardon. But I am sure you are getting just a little uncharitable. George Watson's letter in this same issue, I think, shows it. Mr. Watson is certainly a good straightforward man, although he may be mistaken, like the rest of us. You will notice, by the date of his letter, that it was not published immediately on receipt, on account of the press of other matter. Friend C., it was myself who put on the heading, and who wrote the foot-note; and it was myself, also, who gave a report, years ago, in regard to a colony of bees that was wintered in the cellar with so very little stores

it seemed as if they must have lived for some weeks without any, comparatively. Accounts have been published in the same line, all through our journals, and many more could be picked up now if it were worth while to look into the matter. Doo-little has had something on this subject already, and perhaps he may enlighten us further. Perhaps we had better lay aside jokes, and ask in sober earnest how long chilled bees may be kept alive.

OUR P. BENSON LETTER.

HEXAGONY HIVE.

UP to the present time thair is (3) three strains of hives; the box hive, the Langstroth hive and the invertable hive. I hev now established a noo strain, whitch makes 4 (four). It is the Hexagony Hive. This is bound to sou-porseed all others, bekoz it is natcheral to bees to bild evry thing hexagony shape. A hexagony is a square with six sides, and that's the way the bees bild thair sells, so a hexagony hive looks natcheral to them and soots their ideah and will attract bees wharever it is poot. In fact, it will attract bees from other hives, as it will be seen in the pickter thay is more bees goin to the hive than is commin away. In this way the hive is always kep strong. Under the hive you see the base whitch is a hexagony cut in 2. On the top is a hexagony surplus department. This is filled with hexagony hunny boxes. A hexagony hunny box is filled sooner than enny other, bekoz it just fits the sells, and the bees will fill it a good eel sooner.

P. BENSON'S HEXAGONY HIVE.

In the summer of 18 hunderd and 86 I made the discuverry that by turnin a hive upside down the bees wood make just twicest as mutch hunny. You see when they find the hive upside down they think thev got in the rong hive, and if thay doant wurk twicet as hard thay think thay will git poot out. But the hexagony Hive ken be inverted on (6) six different sides, so thay think it's (6) six different hives and thay will poot in 6 times as mutch hunny.

Now sum buddy will go to wurk and git up a 8 square hive and think he ken git 8 times as mutch hunny, but heal be phooled. A 8 square hive izzent

natcheral, bees doant bild sells with 8 sides, and thay will see through the desepsbun.

Rites for the Hexagony Hive for sail. State rites is (5\$) five dollars apeace. This will entigtel the oaner to yuse the hive on his oan land enny whair in the State. If he moves into a different State heal hefto by another rite. But he mussent make enny hives. He ken by the hives of me at cost. Thay cost 5 dollars \$ apeace, whitch barely pays for the matearial and my time a makin of them. My time is middlin valyuable.

This hive is a invenshun whitch I am not asham-ed to go down to posterity.

P. Benson, A. B. Sighentist P. S. Mr. Root, what roilty wood you give for the excloosiv and sole rite to make, sell, and yuse the Hexagony Hive? This wood keep the thing so nobuddy else cood make or yuse them, and wood dirty mutch giv you a monop-pelly.

P. BENSON, A. B. S.

BLASTED HOPES.

WANTED—A PARTNER IN BLASTED HOPES;
SOMETHING ABOUT THE BEVELED EDGE.

BRO. ROOT:—You ask for reports discouraging. Well, here we come, complaining that our bees will not swarm, nor store any honey in the boxes above the brood-nest. I have seven colonies in Langstroth hives, ten frames, that have not cast a swarm in two years. Tell P. Benson to send me some of the seeds of that celebrated apple-tree of his. Now as to honey for the family, that is just a rarity. I sent to Jas. Heddon three years ago, and got 300 lbs. of his fine honey, and we lived fat while that lasted, but that has given out long ago. Tell Bro. I. R. Good, of Nappanee, Ind., to move down here to my house, and bring all of his bees with him. I want him and his bees. If he can't come, tell him to send me his bees any way. We are not overstocked here. I have a fine apple-orchard of 100 or more trees under which I can set our hives. I want a partner in the bee-business—a male partner—one who likes bees. I have a female partner for life in other things, but she don't like bees. She sometimes looks "bevel edged" at me, and says, "You had better put down those old bee-journals and get your Bible." Mine are all black bees, and they can sting too. I tried to divide a colony yesterday evening, and now my face is all swollen up. They came at me zip, zip, zip, and then I skip, skip, skip. Send me a male partner, or else put me in Blasted Hopes.

J. G. NANCE.

Bellevue, Ky., June 3, 1887.

Many thanks, friend N. We have heard of women looking sharply at their other half, but we never before heard of one looking "beveled edge" at him. The term, even if newly coined in the sense in which you use it, is full of meaning—at least to a bee-keeper. Now, then, where is the male partner who will offer himself to our friend?

ALL DEAD BUT TEN.

I packed last fall in Doolittle chaff hives, and according to his directions, 21 good colonies. May 11, 1887, all dead but two. As near as I can find out, two-thirds of the bees in Fond du Lac Co. are dead. Lamartine, Wis., May 11, 1887.

C. S. NASH.

TRANSFERRING WHEN BEES ARE IDLE.

A LITTLE ADVICE.

ON the 18th inst. I transferred a colony of bees at Langhorne, Pa. The weather was very warm, the bees were idle, and hanging out of their hives. First I set the old box hive on a piece of carpet and set a two-story Simplicity hive in its place. Next I opened the box hive, and the bees flew around me as if three or four colonies were swarming at once; then for the first time I used a bee-veil. It was very useful. The bees from 3 colonies flew so thick I could not see what I was doing. I used my smoker for a few minutes, which settled the bees I was transferring, but robbers then became more troublesome; and when I opened the old box hive they grew still more vicious. They clustered around the new hive as if they were swarming. For a time smoke would not check them; and after they were checked they would repeat as soon as the smoker was idle. I looked to see where they came from, and found many of them came from two adjoining hives, so I gave each of them a little smoke, which stopped the robbing. Not only honey-bees, but even bumble-bees made a visit to the box hive. They had a good share of the smoke too. The combs were soft, like dough. I could not help letting the honey run, because the combs were not tough enough to hold together. I managed to get the brood-comb in nicely, but the honey-comb was very hard to be made to stay in frames. I put what honey I did not transfer, into a wash-boiler. The robbers flew about the boiler, watching for a chance to pop in; and whenever I would open the boiler, a lot would rush in. The hive was small and had no place for hot air to escape. I suppose the cause of the combs being so soft was because the bees were packed inside and outside of the hive. The honey of this hive was the exact color of buckwheat. Can any apiarist tell what kind of honey it is? I could not find the queen. They were black bees. They bunched so much that it was impossible for any apiarist to find her. It took me three hours to transfer that one colony of bees. I will never transfer a hive again when bees are idle. I will wait until they commence working, and I advise all bee-keepers to do the same. I never have any trouble in transferring when bees are busy; but let them alone when they are idle, unless you have a bee-tent.

E. E. GRAY.

Yardley, Pa., May 24, 1887.

Friend G., I have been through just about such experiences as the one you mention, and I long ago decided that I never wanted to transfer any more bees when they were not working. The combs were softened, as you suggest, by the heat developed by the bees in that small close hive. I pity the man who gets into such a fix as you were.—Now a word about smoking bees to prevent robbing: Every time we get a new man at work in our apiary, I have quite a time to make him understand that he can not stop robbing by the use of smoke. When a colony is being robbed, the first thing to be done is to induce them to defend themselves; and how can they repel their assailants, or organize themselves for a good square fight, when smoke is being continually blown in

their eyes? A few days ago they had some trouble at the Swamp Apiary. Some bees just purchased were set in a warm place, and they began passing the honey through the wire-cloth frames over the top of the hives. Robbers soon came in great numbers and made desperate attempts to force the entrances of several hives that had just been located. One of the boys said he kept the robbers away by smoking them for half an hour, and then he was obliged to stop in order to replenish his smoker, and he had to go quite a little distance to get some rotten wood. I told him that I very much preferred he should have no smoker around when bees were robbing. If you can find the hives from which the robbers are coming, it will do very well to smoke them; but by no means smoke the bees that are being robbed. Make the hive tight, contract the entrance, shut up or get out of the way every bit of loose honey, and then get the besieged colony to defend themselves. Where robbers are hovering around the hive trying to get in, you will often start robbing right speedily by driving the sentinels of the hive back into their home, with a smoker.

A LETTER FROM OUR OLD FRIEND A. BUNKER.

He Reports Further in Regard to Apis Indica and Apis Dorsata.

HONEY FIFTY CENTS PER POUND.

FRIEND ROOT:—My long silence has not been caused by loss of interest in the great "bee-family" or the bees; but the many cares of a large mission, in time of war, have called for all our strength. Over a year ago the British army marched to Mandalay and easily dethroned King Theebaw, and thought the work of subjecting Burmah complete. But, how mistaken! During the last rains, where troops were shut up in towns near the large rivers, almost the whole Burmese fighting population in the interior formed themselves into bands, numbering each from ten to three thousand, fairly armed. This alarmed the authorities, and at the close of the rains troops were rapidly brought into the province, till the British forces of all arms here numbered fully 35,000 men. These troops were broken up into small bands also, and scattered all over the country to meet the many bands of dacoits, so called, now ravaging the country with pillage and fire. The larger bands were first attacked and broken up, and at this date the official bulletins announce the country as "pacified throughout its whole extent." This, however, is not apparent to those who dwell among the people. The country swarms with small bands of tens and fifties who move rapidly from point to point, and burn, kill, or rob, as they will, wherever they can do so without fear of English guns. The object of these marauding bands seems to be plunder, and they care not what destruction they work in securing it. Being great cowards, they seldom attack the English or the Karens, but they are terribly cruel where they have the power. The most cruel tortures are inflicted, even on their own countrymen, in order to force them to reveal their hidden hoards. The helpless of every age are

roasted before the fire, beaten with rods, pricked and cut with knives, covered with kerosene oil and set on fire—no words can describe the ferocious brutality of these idolaters.

The Karen Christians have been most loyal and helpful to the government, but the officials have been obliged to work with them largely through us missionaries, as we alone understand the Karens and their language. The Burmese have, of course, been especially hostile to the Karens, because of this loyalty, and in the first few months of the war they did them much harm, burning their chapels and schoolhouses, and destroying their villages. The government, however, soon recognized the help they had in the Karens, and organized them into "levies," with arms for general defense—a sort of "home guards." They have done much in putting down lawlessness. So much has this once "no people" risen in public favor and interest, that an officer, of some experience in the province, has thought them worthy a book, and has recently published one concerning them.

This war has thus brought to the front the Karen Christian, but it has also, under God's providence, done more. It has taught the many heathen Karens the difference between the God of the Christians and the dumb idols of the Burmans, and they are now moving rapidly toward Christianity in many parts of the province.

In all our cares of a Christian population of eight or ten thousand, during these troublesome times, our recreation has been the "blessed bees." We have had eleven swarms under study during the year. Observations given you in previous letters concerning the *Apis Indica* have been confirmed. We have been able to overcome the propensity of this bee to abscond, or migrate, at the end of the two breeding seasons, by cutting out all brood comb as soon as the young bees have hatched out. It would appear that this bee migrates only on account of the moth; for where the moth can not reach the comb the bees almost always remain; yet even then they bite down the old comb, after using it for breeding purposes two or three times. I have kept one swarm two years, and several a year, by thus cutting out all dark comb at the end of the breeding season.

Efforts to import European bees into this country have not been successful. Mr. Douglas, of Calcutta, left England early in the year on his return to India, with 20 stocks of Italians, and reached Calcutta with only two alive. Shortly after reaching India Mr. Douglas was taken ill of cholera, and died. So has passed away perhaps the only skilled beekeeper in all India. He was indefatigable in his efforts to introduce the European bee into this vast country.

This is a good year for *A. Dorsata*. Swarms of this bee have returned in large numbers, and those Karen villages domesticating this bee have large yields of honey. One village near here expects to gather about thirty barrels as its harvest of sweets.

At the time of writing, I am in camp on a lone mountain in an old forest. A short distance from my camp stands a gigantic wood-oil, or dammer-oil tree. It is nearly four feet in diameter, and runs up nearly one hundred feet without a limb, as straight as a candle; then the limbs branch off in a nearly horizontal position, and under these the *A. Dorsata* have their brood-combs. A dozen or more, from two to three cubits in length, are seen. What

a roar of humming wings you hear as these bees hasten to and fro with their loads of sweets!

Extracted honey is selling here at about 50 cts. per pound. Section honey! Ah! I wish you bee-folks could have this market for a while. I have succeeded in teaching my little *A. I.* swarms to put honey in sections, by giving them all the honey they can store away; but the honey thus stored is dark and thick, though the combs are beautifully white. This section honey is very different from my remembrance of home honey. A. BUNKER.

Toungoo, Burmah, April 30, 1887.

Friend B., I suppose we are to understand that the *Apis dorsata* has, then, been really domesticated by the natives. Now, if you have told us how they domesticate them, I do not remember to have noticed it. Do you mean the colonies hanging on those great trees 100 feet to the first limbs? In that case they may be domesticated, but I should think the domestication was pretty high up. Have they ever been brought down to the ground, and made to work in hives, and can it be done? Why in the world do your people hold honey at 50 cts. per lb.? It seems to me that, with only a moderate pasturage, bee-keeping would pay wonderfully at these figures. Why, we could almost ship our nice section honey to you, if we could be sure of getting any thing like the above price. You say one village expects to have about 30 barrels. Well, if those 30 barrels is to be *Apis dorsata* honey, that is another big fact. By the way, if we had a barrel here that we could declare positively was gathered by the *Apis dorsata*, I do not know but that we could get 50 cts. a pound. We could for a limited quantity, any way.

DO BEES EAT GRAPES?

SOME ORIGINAL FACTS FROM FRIEND DOOLITTLE IN REGARD TO THE MATTER.

WE clip the following from the *Rural New-Yorker* of June 11:

Much discussion has taken place of late in the bee-papers and elsewhere relative to bees eating grapes, the bee-keepers insisting that bees do not attack sound grapes, some going so far as to claim that it is impossible for the bee, on account of the construction of its mouth, to bite into a sound grape, while many grape-growers claim that bees do bite into and devour sound grapes. In this the latter are upheld by the late decision in California, by a jury who decided against the bees in that "bees and grapes" lawsuit. However, as this case has been appealed by the bee-keepers, it may be decided differently at the next trial, when the necessary proof is fully brought in. I am not among the number who claim that a bee can not bite into a sound grape, for I see no reason why an insect which can so gnaw as to enlarge the entrance to its hive made of solid wood, or bite holes through cotton cloth and other fabrics, could not do so if it were intent on such a procedure; but I do claim that the bee never does bite into a sound grape, for the simple reason that it was never made to bite into even the most delicate flower to get sweets, and that all openings made in grapes, peaches, pears, and plums, can be traced to other sources.

Among the bee-hives in my apiary are many choice varieties of grapes which were never worked upon by the bees to any extent until last season, at which time the vines of certain kinds were literally swarming with bees. The kinds most injured were the Lady and Belinda among the white; the Salem and Agawam among the red, and the Worden among the black. On a careful examination, I

found that the trouble with the Worden and Belinda came from their cracking open; but for a time the work on the others baffled me; for it was not until I had nearly made up my mind that the bees were the real offenders that I discovered the truth in the case. How I knew that the two above-named kinds cracked open was, that I found scores of them so cracked early on dewy mornings, before the bees had touched them, while the rupture was yet fresh, giving these a very different appearance from that of those worked upon by the bees the day before. If I had not examined them thus early, I should not have detected the cause; for by 10 o'clock the bees were so thick on them that I could see no difference between the old and newly cracked ones. But when I came to apply the cracking test to the rest of the grapes it failed to reveal that such was the cause of the trouble. I examined the bunches of grapes very carefully in early morning, but found all sound, except those worked upon previously, and again at 10 o'clock I watched the same bunches and could not discover any thing different, except that bees were all over them, sucking at the ruptured ones which I had marked in the morning, while on the next morning I found that many more of the grapes had been worked upon after my 10 o'clock examination. I expected, of course, if the bees were the offenders that they would tear the grapes open when they first came on them, while they were hungry, so did not watch in the afternoon.

After finding that there was no mistake in that the bunches of grapes were gradually being eaten up, I began to watch all day, reasoning that the bees, after sucking those dry which were open at 10 A. M., would tear open others, and I wished if possible to detect them at it. After watching all the forenoon I became almost discouraged; but at about 1 P. M., I saw on a bunch of grapes a stinging wasp, such as build paper nests in nooks and crannies about our buildings. In a moment more I saw this wasp bite a triangular piece of skin out of a sound grape, and go to sucking the juice from it. The bees now tried to get at the ruptured place, but the wasp kept them away with its feet, so that in no case did I see a wasp and the bees getting juice from the same grape. I soon saw more wasps, so that by two o'clock I judged that at least 100 grapes had been opened on a single vine. At about three o'clock all the wasps had gone, and the bees were having a good time at the grapes which the wasps had ruptured, but in not a single instance could I detect a bee opening a grape, although the bees ran frantically over the grapes in search of places from which to get the juice.

Later on I detected the work of mice on one vine which stood near a pile of rubbish, the mice seeming not only to like the sweet juice of the Agawam grape, but the seeds as well. It was easy to tell the work of the mice, for they tore open nearly every grape of the bunch worked upon. This gave the bees a fine chance on such bunches the next day. Thus after carefully watching all fruits worked upon by the bees, and in these cases of the grapes nearly deciding against these industrious insects, I wish to place it upon record that, so far, I have found the bee innocent, and do not believe a bee ever attacked sound fruit, although I allow that it could be so, if it had been ordained that it should thus get its living. It seems to me that it must be plain to all, that the bee was created for the fertilization of flowers, and that the honey was placed in there to attract the bees for that sole purpose; for all trees and plants capable of self-fertilization secrete no honey, as all will find if they give the subject close attention. G. M. DOOLITTLE.

Borodino, N. Y.

The above gives some light on the subject, but still it leaves the impression that bees are not much to blame in the matter—they work only on grapes that have been first spoiled by other insects. The question then arises, Are bees really a hindrance to grape-growing? that is, do they damage grapes that otherwise would have been salable? It seems to me, the bees are still a little more to blame than even friend Doolittle puts it. I have seen clusters of grapes that looked tolerably fair before the bees had been over them; but after they had

covered the bunches up, and fought over them, there was not much of any thing left. I can not say now that wasps were not the cause of their destruction, as in the case friend D. mentions; but I hardly think they have *always* been present when grapes have been entirely used up by the bees.

ALSIKE CLOVER.

PROF. COOK OFFERS SOME SUGGESTIONS RELATIVE TO THE DISPUTE BETWEEN MUTH AND CORY.

EDITOR GLEANINGS:—As per your request on page 428, I will write a word as to the matter of alsike clover. I will first quote from Dr. W. J. Beal's new work on grasses, which, Mr. Editor, I think you ought to keep in stock, and, with the many other valuable works which you sell in that line, distribute it among your many patrons. I assure you, as we should expect from the author, it is a most valuable work. Dr. Beal, under the head of "Alsiike Clover," after describing the plant, with a good illustration, says: "Found in Europe, North Africa, West Asia: introduced into North America. Its common name is derived from a parish in Sweden. In appearance it is so nearly intermediate between red and white clover that Linnaeus supposed it was a hybrid, and hence its specific name—*Trifolium hybridum*, Linn. It is not a hybrid. Alsiike likes rather moist land containing some clay. It is smoother and more delicate than red clover, and the stems are weaker—so much so that it is quite likely to lodge. The stem remains green after seeding. It stands dry weather well, is not apt to winter-kill, the flowers continue for a long time, and abound in nectar, which can be reached by honey-bees. Alsiike clover has a good reputation for pasture, and is a favorite with bee-keepers. It frequently yields from 3 to 8 bushels of seed to the acre, and these are only half the size of those of red clover, hence only half as much seed is sown to the acre. The seed is produced from the first crop, though it is often pastured a while early in the season. It is two or three years in coming to full size, and does best for pasture when sown with some stout grasses. The after-math is very light. When ripe it shells more easily than red clover, and is more apt to waste, hence more care is needed in the harvesting."

No one will question such an authority, and hence the idea of atavism, to account for the phenomenon as explained by Mr. Muth, is at once set aside.

As alsike is a distinct species, and not a hybrid, a variation so marked that any one would mistake it for red clover is not within the range of possibilities; at least, it so occurs to me. Again, the seed is very different—as Dr. Beal says, only half as large. Mr. Muth also makes this evident. Still, the average man has rarely had his observing faculties so cultivated that he might not make a mistake. A dealer like Mr. Muth, or a scientist like Dr. Beal, could not be deceived, while a farmer might quite likely not note the difference. Many of us, having eyes, see not, especially little things.

Again, red clover and alsike clover are very closely related; and granting the seed to be equally good in each case, we might safely conclude that conditions that would lead the seeds of one to germinate and grow would also effect a like result with the other. If the seeds were all good, my observa-

tion would lead me to say that, if the red-clover seed grew, the alsike would do the same. Still, there is room for a doubt here. The one might be much drier, possibly, than the other, and so be more tardy in its development.

In such a case as that between Messrs. Muth and Cory, then, I should conclude either that Mr. Muth was mistaken in the seed—the more likely supposition, it seems to me—or else that Mr. Cory was mistaken in his identification of the plants, which seems hardly possible. It is barely possible that very excellent land, with as excellent care and tillage, might produce specimens that would deceive a man of feebly developed observing powers. However, I should not expect this. No one who knows them could doubt for a moment the honesty, either of Mr. Root or of Mr. Muth; but it is quite possible that, in their great hurry and press of business, a lot of clover might be brought in that should escape the usual close inspection, and pass out similarly unscrutinized, and thus a sample of red clover go forth as alsike. The fact of their large business makes this all the more possible. True, special circumstances make this less probable in the case of Mr. Muth; yet which one of us has not had experience that proves it is easy to be mistaken, even when we are most sure?

I have stated this case to Dr. Beal and to one other close-observing scientific gentleman, and both agree with me in the conclusions as shown above. Should I sow alsike (?) clover seed when no clover had grown for years, and yet where the ground had been cultivated, and red clover appeared, I should not doubt for a moment that I had mistaken the seed.

A. J. COOK.

Agricultural College, Mich., June, 1887.

Why, my good friend Cook, I am afraid you do not read GLEANINGS any better than I read some other books and journals. Dr. Beal's work was noticed in quite a lengthy editorial, and we do offer the book for sale.—Your reasoning I should pronounce sound, even if it reflected a little on myself. There is one other difficulty, however, in the matter of the clover seed I sent to friend Demaree. At that time I had never dealt in any sort of red-clover seed, and there was none in our establishment—or, at least, there was none to my knowledge. Our alsike was put all together in a large bin, and friend Demaree was furnished seed from this bin, with all the rest of our customers. Had we been dealing in red-clover seed, as we have been of late years (peavine clover), I should have at once decided that the clerks had gone to the wrong place. In Muth's case, it is quite a mystery; for I agree with you, that both parties seem to be honest and straightforward.

THE WATER WE DRINK.

OUR WELLS AND CISTERNS; SANITARY DRAINAGE, ETC.

FRIEND ROOT:—GLEANINGS is just at hand. I, too, was very much surprised at Heddon on septic diseases. He has for years been giving us what he considered the cause of bee-disease, and I think he may now with pleasure and profit give his attention to some of the ills that afflict the human family. It might be that his throat

difficulties arise from some other cause than bee-poison. I think your article upon the subject of drainage and vaults will awaken inquiry. I have not used a vault for over 30 years. I use a box which rests upon two pieces of scantling. I often scatter in some ashes, or, what is better, a little dry earth; and when it is full I draw it out and dump into the ash-pit, and in spring and fall I haul to the garden and spade in.

I have known of several cases of typhoid fever, diphtheria, and death, from bad drainage and poisoned well-water. People will say it can not be *their* well-water, for it is clear and sparkling; nevertheless, there is death in the cup.

About six years ago I had the pleasure of hearing a lecture upon this subject by Prof. Kedzie, while I was in the Sanitarium in Battle Creek, Mich. I inclose a scrap which is the substance of that lecture, that I fortunately preserved. Use it as you think best. I am deeply interested in the subject. I look upon bad drainage and vaults as two of the greatest curses that afflict the human family, and a disgrace to our civilization.

GEO. THOMPSON.

Geneva, Ill., June 18, 1887.

The paper inclosed by friend T. seems to be so very valuable, and striking as it does right where the interest of many of our readers has been centering for some months back, we think it worth while to give the article entire.

The present age is characterized by a thorough and exhaustive examination of the relation of causes to physical health and life. Every alleged cause is also subjected to the cross-examination of test-tube and crucible, balance and spectroscope. Every witness must bear the tests of physical science. Sanitary science now *demand*s causes as well as results, and has planted its feet on the solid platform of positive physical science.

Fifth is the capital crime of physical existence. Air and water are the great purifiers and prime necessities of life. To breathe is the first and last of life. The moments of our existence are but pearls on a thread of air. The thread breaks; life is gone. Less obviously, but no less certainly, water reaches from birth to burial. Air has no vital action in the absence of water.

The oceans of air are too vast for human defilement in mass. It can be defiled only in spots. Water we deal with only in detail, and in small amounts it is easily capable of defilement. The special office of water is to purify; but in purifying it becomes itself impure. It comes to be soiled, and therefore is useless when soiled. It must be purified or got rid of. To purify, it must be pure. If filthy it becomes a source of danger.

By soil-water is meant water which is in or drawn from earth, water which has been freely in contact with the soil by falling on it and percolating and filtering through it and thus being connected with materials in soil held in suspension and solution. It is the water of wells and springs, not of lakes and rivers, which is exposed to the oxidation of the air and the effects of the agitation of currents. The spring pumps itself all the while, but the well is pumped at intervals, and so offensive materials may be worse in wells. The power of dilution of specific poisons like cholera or typhoid is not perfectly known; but the danger of non-specific poisons is diminished by dilution.

Water may exist in soils in three forms:

1. "Hygroscopic" water, which may exist in the dryest soils, as shown by minute drops when heated in a test-tube.

2. "Capillary" water, which makes soil damp and of darker color, but will not flow out by the action of gravity.

3. "Free" water, which flows in drains, springs, and wells. With this the sanitarian has to deal.

The water which will flow into a well may be regarded as drainage from surrounding pervious soil. It will flow with a pressure in proportion to the depth of the well, diminished by the friction of water on the particles of soil. The distance from

which water will flow into a well depends on the soil. [This, Prof. Kedzie represented on a chart by an inverted cone, with its base at the surface of the soil, and its apex touching the surface of the water in the well.] The diameter of the circle of surface varies with the porosity of the soil. If a tenacious clay, the diameter of the surface of this cone of filtration may be only 30 to 40 feet; while in sand or gravel it may be 60 to 200 feet. Any soluble material within this cone of filtration will flow into the well, calculating the soil to be uniform in texture. But if there are strata of unequal permeability, or if there are cracks, seams, or water-paths in impervious clays, the water will follow these seems almost an indefinite distance, and there will be a wide departure from the limits given. Materials without the cone may come through these seams.

This is an appalling picture, but there are certain conservative agencies to tone down the startling outlines. The soil is not a passive agent, but may act on such substances in solution in water in three ways.

First. As a simple mechanical filter to separate substances held in suspension. The texture of the soil is the chief factor in this action. [This he illustrated by the filtration of a blue precipitate thrown down in well-water by the action of ferrocyanide of potassium. The colored material was left on the soil in the tunnel, while the water was clear, proving the soil a very perfect filter.]

Second. Soil may act as a mordant to fix and remove coloring materials from solution in water. In 1836, Bronner, of Baden, noticed that color, odor, and nearly all taste, are removed from filthy water by filtration. All have noticed that subterranean waters are usually colored.

Third. Soils may produce chemical decompositions, making changes that will not take place in simple solutions. A similar experiment reveals the brown deposit of chloride of ammonium cast by a re-agent in well-water, but a mere discoloration on filtered water, showing the soil had taken out almost every trace of ammonium. This is a fact of highest importance to the sanitarian. This power, however, is limited. By using the soil made foul by the last experiment, a considerable deposit is found after filtration, showing the power of the soil to withdraw these materials and fix them in soluble and safe forms is limited.

Soil is a sanitary filter. It removes color, odor, and substances, but this power is limited. The greater the amount of soil for filtering, the longer is the time before this exhaustion of power takes place. The amount of soil has an intimate relation to its power of purifying. Hence the value of deep wells, provided the water filters through the entire amount of soil. The sides of the well should be made impervious, and then the water must filter down. Supposing the sides are of iron, there is some assurance of safety. This is true of "drive-wells." The water can not come through the sides; also worms and reptiles can not get into it. A drive-well is a very safe form of well.

But there is danger that the limit of power be exhausted by increase of contamination. Think of a privy-vault or cesspool within this cone of filtration. If this appears revolting, blame the facts.

"See if all is well with your well." Neglect which borders on crime could hardly go further. I here quote from Buck's *Hygiene* as follows:

Dr. Simon has described this common and deplorable neglect in the following terse sentences: "There are houses, there are groups of houses, there are whole villages, there are considerable sections of towns, there are entire and not small towns, where prevails slovenliness in every thing which relates to the removal of refuse matter—slovenliness which, in very many cases, amounts to utter bestiality of neglect in the local habit; where within or just outside of each house, or in spaces common to many houses, lies for an indefinite time, undergoing fecid decomposition, more or less of the putrefiable refuse which house-life and some sorts of trade-life produce: excrement of man and brute, garbage of all sorts, and ponded slop-waters; sometimes lying bare on the common surface, sometimes unintentionally stored out of sight; re-collection in drains or sewers which can not carry them away; sometimes held in receptacles specially provided to favor accumulation, as privy-pits or other cesspools for excrement and slop-water, and so-called dust-bins, receiving kitchen-refuse and other filth. And with this state of things, be it on a large or small scale, two chief sources of danger to life arise: One, volatile effluvia from the refuse pollutes the surrounding air and every thing which it contains; the other is, that the liquid parts of the refuse pass, by seepage or leakage, into the surrounding soil, to mingle there, of course, in whatever water the soil yields, and in certain cases thus to occasion the deadliest pollution of wells and springs. To a really immense extent, to an extent which, indeed, persons unpracticed in sanitary inspection could scarcely find themselves able to imagine, dangers of these two sorts are now prevailing throughout this country, not only in their slighter degrees, but in degrees which are gross and scandal-

ous, and very often, I repeat, truly bestial. And I state all this in unequivocal language, because I feel that, if the new sanitary organization of the country is to fulfill its purpose, the administrators local and central, must begin by fully recognizing the real state of the case, and with the consciousness that, in many instances, they will have to introduce for the first time, as into savage life, the rudiments of sanitary civilization.

The extent to which soil is polluted by excreta and other refuse matter, in the rural and small urban districts in England, and the danger of the contamination of drinking-water from this source, may be learned from the report of the late Royal Sanitary Commissioners, in which they say, that, estimating the town population of Great Britain at about fifteen millions, the remaining twelve millions of country population derive their water almost exclusively from shallow wells, and these are, so far as the commissioners know, almost always horribly polluted by sewage and by animal matters of the most disgusting origin. The common practice in villages, and even in small towns, is to dispose of the sewage and to provide for the water-supply of each cottage, or pair of cottages, upon the premises, in many instances, by garden attached to each tenement, or pair of tenements, two-holes are dug in the porous soil. Into one of these, usually the shallower of the two, all the filthy liquids of the house are discharged. From the other, which is sunk below the water-line of the porous stratum, the water used for drinking and other domestic purposes is pumped. These two holes are not infrequently within twelve feet of each other, and sometimes even closer. The contents of the filth-hole or cesspool soak away through the surrounding soil, and mingle with the water below. As the contents of the water-hole, or well, are pumped up, they are immediately replenished by the surrounding disgusting mixture, and it is, therefore, not very surprising to be assured that such a well does not become dry, even in summer. Unfortunately, excrementitious liquids, especially after they have soaked through a few feet of porous soil, do not impart the palatability of water, and the polluted liquid is consumed from year to year without a suspicion of its character, until the cesspool and well receive infected sewage, and then an outbreak of epidemic disease compels attention to the polluted water. Indeed, our acquaintance with a very large proportion of this class of potable waters has been made in consequence of the occurrence of severe outbreaks of typhoid fever among the persons using them.

Prof. Kedzie added:

"I do not know that any condition at all corresponding to this can be found in Battle Creek, but I have had the misfortune to find analogous conditions and similar results elsewhere in this State."

Prof. Kedzie gave several instances which had come under his observation. One family was always sick. There was no constitutional reason, and they were people of good habits. He suspected the well. The husband smelled the clean water, and said, "Doctor, you must be mistaken." He went lingeringly down to the grave; a nephew followed, and a son. The widow became bed-ridden. The premises were sold to a good family, and they became sick. He insisted on a new well, and they regained their health.

In Lansing, a man's only daughter was sick. He did not believe it was the well, but a conduit was found from the privy to the well, and the water was exceedingly foul. Many were sick. Standing by the well, with a dipper he could throw water on fire privies. One of the best men in Lansing sickened and died. The well was pronounced bad. The family took it personally, but a sewer was found broken within three feet of the well. Water from town pumps had been found to be very bad in some places. If this is the condition of the town-pump, what is the condition of the town-hearse?

There are many widows because disease and death have been carried into the house by the water-pail. The question arises, Must careless surroundings bring this? Such is the law of sowing and reaping. "The law of the harvest is to reap more than you sow. Sow an act, and you reap a habit; sow your habit, and you reap your character; sow a character, and you reap a destiny." Nature is inexorable, and knows no mercy. Her laws are written on two tables of stone. The first is, "Do this and thou shalt surely live;" the second, "Thou shalt not do that, lest thou die."

Nature has placed animal and vegetable life in reciprocal relations to each other, in opposite scales, in the balance of life. Plants thrive on the remains of animal life, and destroy the bad. From the poisonous carbonic acid they give back the life-sustaining oxygen, and take the deadly carbon. The poisonous remains of animals are the appropriate and grateful food of plants. When man puts asunder what nature has put together, disease comes in as a protest against the disturbance of nature's harmonies. From the organic nitrogen and phosphorous thrown out as deadly waste from animal systems, the plant forms the gluten and albumen of muscle and brain. Animals and vegetables are dual and reciprocal forms of life. Each feeds and protects the other. Only when put asunder do cholera, typhoid, and diphtheria, step in as avenging ministers of violated law.

Crowded cities disturb the reciprocal relations of

these two, and are unnatural. When we place ourselves in abnormal relations we must be more careful. We should place ourselves under the green flag of nature's protection, and cherish our grass-plats.

In conclusion, the speaker beautifully alluded to the vision of St. John in the apocalypse, of the pure river of water of life, clear as crystal, and of the tree of life on either side of the river; the leaves of which were for the healing of the nations. Blessed trees of life, whose leaves even here on earth are for the healing of the nations!

THE DISPOSAL OF SEWAGE IN LARGE CITIES AND TOWNS.

THE WAY THE MATTER IS MANAGED BY THE FRIENDS OVER IN ENGLAND.

THE disposal of sewerage was at one time a matter of very great trouble and expense to many of the towns in England, not only caused by the trouble of collecting and carting it away, but by numerous lawsuits on account of the nuisance caused by the great heaps of refuse, and the fouling of the water of the rivers and brooks into which the liquid portion flowed. Many methods were employed. One large town, after buying a farm to run it on, and going to great expense, which failed on account of the land being so low and already too wet, built a large factory to convert it into manure in a dry state, with an immense chimney-stack to carry off the vapors. Sewerage-farms, however, seemed to be the most rational way to dispose of it, and get rid of the trouble; but it was a long time before any of them were able to make expenses. One of the first to make a success of it was Bedford, and I will take that town as an example. The fact of its being the place where Bunyan was imprisoned may add some little interest to the place. I was there in 1879, and the old jail was standing in much the same condition as when he was an inmate.

The first step toward the solution of the sewerage problem was the construction of two sets of sewers—one for rain or storm water only, and the other set for the sewerage and water used to flood them. These last empty into large tanks, constructed for the purpose. These are many feet square, and about eight feet deep, and walled and floored with bricks. The sewerage is let into these in turn, and a certain amount of water, if necessary to reduce it to the proper consistency. Then it is all stirred up by chains worked through it by steam power. After a time it is allowed to settle awhile, and then the water is run off, comparatively clear, on to any portion of the farm ready to receive it. All the water being run off, the sediment is thrown out and given away, but more often carted away at the expense of the town; for by repeated trials it is proved to be of no value, all the fertilizing properties having been carried away by the water.

Rye grass is the principal crop grown, that being more readily disposed of. It is cut several times a year, averaging 40 tons (of 2240 lbs.) per acre per annum; in fact, some part is always being cut. It sells to horse and cow keepers at 25 cents per cwt. (112 lbs.). They also grow large crops of mangel-wurtzel, Swede (rutabaga) cabbages, onions, etc. When I was there last, the mangels would average about 35 lbs. weight each. A friend of mine told me he sent a boy with a horse and cart to get a load, and he came back without any—said there were none he could lift into the cart. They had onions

valued at \$350 per acre—2 cents per lb. being the usual price. To work such a farm with any chance of success requires a porous subsoil, well drained, so that the water will all get filtered, and run away so pure that any river or brook into which it runs may not be any the worse for it. The filtering power, or capabilities of the soil, should be so great as not to be liable to be overtaxed, for you will see that it is not a case of taking and irrigating just as much and as often as you please, but you have to dispose of all that comes; and in a wet season, when you are least able to get rid of it, more will come than at other times.

In England, very few farms are owned by those who work them for a living. Nearly all are let out to yearly tenants, subject to six months' notice to quit. Leases are the exception. Good land brings a yearly rent of ten or twelve dollars per acre; some pasture land much more. There is always a written agreement, signed by both landlord and tenant, the provisions of which are very stringent.

No hay, straw, roots, or manure, can be sold off, excepting potatoes; no field is to be sown with two white straws in succession—that is, wheat, barley, or oats, must not follow one another; no grass is to be mown for hay without a corresponding dressing of manure. The most generally approved plan is what is called the "four-course" system, which has to be worked much as follows:

FIRST YEAR.—After the land has been well worked, a heavy dressing of barnyard manure is plowed under, and some artificial sown broad cast and worked in. The crop planted or sown has to be turnips, Swedes, or mangels. Half of these, at least, have to be eaten on the ground by sheep. The rest can be hauled home to be fed to the stock kept in the yards during the winter.

SECOND YEAR.—The ground having been plowed and prepared in time, barley or oats, but more frequently barley, is sown, and with the barley a mixture of rye, grass, and clovers.

At harvest-time, when the barley is harvested, there is a good pasture of clover and grass which comes in very handy for the young lambs not long weaned, and can be grazed all winter, and stands for the crop of the

THIRD YEAR.—This can be either pastured the whole of the season, or only part of the time, and mown once for hay. In either case it has a good dressing of farmyard manure, some time during the summer, and in the fall it is plowed under for wheat, which is the crop of the fourth year, and completes the four courses.

There will be a better crop of wheat if the clover has been mown for hay than if it has been all eaten off. The cutting causes fresh roots to strike into the ground, and these, which seem to be very nourishing to the wheat, give better results than even the manure left on the field by the stock that eats off the crop. Something was said in your instructive and always welcome journal about 37 bushels of wheat per acre being a large crop. My father is still living, and working a farm near Kidderminster, England; and by following pretty well the system described he gets 60 bushels of wheat per acre. If the farmers working the old worn-out farms of England were to raise no more wheat per acre than is made on the fertile and inexhaustible soil of this country, they could not pay their rents.

Hondo, Tex., Mar. 31, 1887. GEO. E. HAILLES.

Friend H., your article is an extremely in-

teresting one to me, and I am a little surprised to learn that the valuable part of all this foul matter can be washed out by stirring it up in the way you mention. The undertaking seems to be quite an expensive one, however. Now, inasmuch as a large part of the expense is due to the water combined with this foul refuse, is it not possible to lessen the labor of moving about from place to place by evaporating a large part of this water, and at the same time avoid taking therefrom any thing valuable for agricultural purposes? Some of the friends thought it was astonishing because I spoke of 40 bushels of wheat to the acre, some time back. An English gardener in my employ (and a Christian gentleman of veracity) says he has seen a field of 20 acres that yielded 72 bushels of wheat to the acre. This was, of course, in England. He said he could not tell what means were employed to secure this wonderful crop of grain; but it was the result of intelligent work on ground that was naturally favorable for such a crop.

ERRONEOUS OPINIONS IN REGARD TO THE HONEY-BUSINESS.

ALSO SOMETHING IN REGARD TO MANUFACTURED COMB HONEY.

ONE of our subscribers forwards us the following, taken from an editorial in the *Wellington Enterprise* of June 8:

At a meeting of the Northern Ohio Bee-Keepers' Association recently held at the Gregory House, New London, it was decided that the next meeting should be held in Wellington next October. We will welcome the gentlemen to our town, but whether the little bee sanctions such meetings is a question. Give us the old-fashioned hive with plenty of white clover and buckwheat for the bee to subsist on, and then let the little insect perform its work as nature has dictated, and we will guarantee a far superior article of honey will be placed upon the market than at present. The bee needs no educating.

Bee-keepers do not propose to "educate" bees; they simply give them facilities for indulging in their ruling passion—gathering honey—in a way infinitely better than that which Nature provides. When it is found best not to build bank-barns for horses and cattle, then it may be best not to provide good hives for our bees. Those who "let Nature have her own way" are those who never hoe their corn, comb their hair, wash their face, build a house, nor sow grain, but simply live wild. Nature gives man a swamp, and he makes a park of it. Nature never has "her own way" so perfectly as through the medium of sanctified common sense.

Now, then, friends of the *Enterprise*, are you not in danger of discouraging enterprise and progress in the remarks you make? When you intimate that honey of the olden time was superior to that gathered by the bees of the present time, are you not making a mistake, and casting a slur upon a great body of honest and earnest people? It is true, that we produce tons of honey now where we used to produce pounds; but I think you are mistaken in intimating that there is a difference in *quality*. Bees gather honey now exactly as they did in the olden times, and I do not believe it true that

either clover or buckwheat has deteriorated one particle in their product. On the contrary, the honey gathered now from alsike clover seems to be considered, without a dissenting voice, quite a good deal in advance of the honey from the old-fashioned white clover. If you will apply to some bee-keeper near you, I think he will give you the means of satisfying you of this.

Two or three years ago our newspapers were full of slanderous statements about the adulteration of comb honey; but most of these very papers have kindly and courteously apologized for their mistaken statements. In regard to liquid honey, it is now offered at too low a price, I presume in your own town as well as elsewhere, to make it an object to adulterate it. Some years ago we offered \$1000 to any one who would inform us where spurious comb honey was manufactured. The offer still holds good; but every effort to find a single pound of artificial comb honey has so far failed.

From the same paper of June 15 we clip the following, which is, as you notice, taken from the *Hartford Journal*:

A process for making artificial honey has been invented, and accepted by all the bees that have tried it. This leaves the bees free to gather honey all the day from every opening flower in the season of honey-making without wasting time as wax-workers.

Now, although the above does not make any definite statement, it is, without question, a sort of clip at this old exploded piece of slander. There is no process in use for making artificial comb honey, and no such thing has ever been invented. Bee-keepers are, as a rule, honest men, and they would no more try to build up a trade with bogus honey than they would by making bogus dollars. If they were so foolish, they would probably turn out just about as badly as bogus-money makers.

MORE ABOUT THE McFADDEN MYSTERY.

WINTERING BEES IN A CHILLED CONDITION.

IN answer to yours of the 13th, asking for information regarding Danie McFadden, I would say that I suppose he is the same D. McFadden whom I had the honor of entertaining for a few days about a month ago, as he was passing through here going west, and I assure you that I was surprised at the intelligence displayed by him in our conversation about bees. I thought, previous to his acquaintance, that I knew all about bees; but I discovered that I knew absolutely nothing, and I therefore am resolved to adopt his method of keeping bees over winter. Either you or I have misunderstood Mr. McFadden as to freezing the bees. I understood him to say that he only *chilled* them. The bee-business is his business, and it is all he wants, as he says that he and his father-in-law, who is an Indian, by the name of Muskegen, or Musquegan, or something like that, have made large amounts of money out of bees; and, to tell the truth, I did intend to make something out of the discovery myself; but I find from your communications that he has kept his word, for he told me that he would like to let the world know of this great Indian discovery about the wintering of bees.

How he made so much money was trading honey for furs; and, as he put it himself, it counted both ways, and he told me that he would not live among the so-called civilized people on any account. He spoke about a love disappointment which was the cause of driving him to live with the Indians, and he afterward married an Indian girl, and claims to be delighted with the life he is leading. He declares that the Indians are more intelligent than the white people; that every herb that grows, they can tell what it is good for in the line of medicine, and they can cure almost any disease. He appears to be clear-headed and reasonable in his arguments, and states that any thing that is not known to the Indians is not worth knowing. I am going to communicate with him, or endeavor to do so, as I am greatly taken up with his ideas, especially about bees, and am therefore anxious to attain all the knowledge I possibly can, and have all faith in what this man states. Why would not this work as well with bees as it does with flies and insects, which we see crawl out when the warm weather comes?

I am writing to McFadden to-day, but do not expect to get an answer before August, if then; but when I do I will let you know, and I shall be pleased to give you any further information that I can.

McFadden was to leave for his home among the Indians about the 26th of last month.

G. WATSON.

Alliston, Ont., Can., April 20, 1887.

Thanks, friend W.; but I am afraid you are placing too much faith in McFadden's statements. No doubt he has learned many valuable facts from his Indian relatives by marriage; but when he declares broadly that the Indians are more intelligent than white people, we must consider him careless and reckless in his statements, if nothing more. If there is a man living who can keep bees over winter, or even for one month, in a chilled condition, we are ready to pay the man for his services in performing the experiment.

30,000 LBS. OF HONEY FROM 80 COLONIES IN CUBA.

VALUABLE ITEMS FROM A. W. OSBORN; COMMENTS ON "OUR OWN APIARY" FOR JUNE 1ST.

FRIEND ROOT:—Last year being a poor one for bees, it was impossible to get more than 80 colonies in condition to store surplus, when the winter flow began. After the heat of summer had gone, the natural conditions for the secretion of honey seemed more favorable, and the 80 colonies we had in condition worked with a vengeance, filling their top stories every week, for nearly four months. At the end of that time we had taken 30,000 lbs. of extracted honey from the 80 colonies. Now, friend Root, this amount of honey was stored by hybrid bees—hybrids from the Holy-Land and Italian queens, mated with black drones; and another thing in their favor, my little son, 12 years old, and myself, took every pound of honey, and did not wear a hat or bee-veil. We have now increased to 500 colonies, and still we use no protection whatever. So much for the abused hybrids. They get the honey all the same, and I would sooner handle our strain of bees, than any pure race I ever saw.

FOUL BROOD IN LARGE APIARIES APT TO REAP-PEAR.

In Ernest's report, June 1, I see that foul brood has made its appearance in his apiary again this spring. "Didn't I tell you so?" After many years of experience with foul brood I have never seen it cleaned out of a large apiary in any other way than fire and water for the combs and hives, and starvation for the bees. I do not say that it can not be done, but I say I have never seen it. We have seen reports where it has been done, but in some of these I *know* there is room for doubt. I can truthfully say, there is none in this apiary. I sincerely hope Ernest may clean it out. I would not fool with it, but go to work and melt every comb, boil every hive, and starve every bee that is infected. In that way he will get rid of it.

HOW TO USE HARD WOOD IN THE BINGHAM SMOKER.

The Bingham smoker, Ernest says he has a little trouble with. After using the Bingham for 10 years, I will tell you how I manage it. I use hard sound wood, about like your hard maple. I saw it up the right length for the smoker, and split it about $\frac{3}{4}$ or $\frac{1}{2}$ inch square, and I prefer to have it pretty much green—not left to season more than a day or two, for in that condition it will burn all that is necessary, throw less sparks, and give a much stronger and denser smoke.

HOW TO START WITH GREEN WOOD.

As I have told you before, our smoker is lighted as soon as daylight, and does not go out until too late in the evening to work with bees. Well, the last thing to be done with the smoker at night is to see that it is freshly filled with wood, then well blown up and set down for the wood to season and char; and when I think it is about right, I lay a little flat stone over the chimney, and smother the fire. The next morning I have a smoker full of as fine charcoal as you ever saw. This charcoal lights very easily when put on top of a few shavings, and will start the green wood off in good shape. It is a little trouble, I know; but I never knew a good crop of honey secured without trouble. When I keep my smoker well filled with green wood I am not troubled with sparks. Take out that little wire screen, between the bellows and fire-box, punch out the wire cloth, and return the casing, to keep the wind from coming out there; for if the wire screen is left in it soon fills up from fuzz from the bellows, and makes it work hard.

QUEENS MISTAKING THEIR HIVES.

As I have told you, our hives here are all painted white, with no difference in looks at all, and set so closely together that many of them touch one another. When I expect a queen to go out I lean an old weather-beaten board up against the white hive, which makes an object that is easily seen, and the queen marks her location by it. When I have two queens go out of hives that sit very closely together, I put a board to one and a red tile to the other (the tiles are about 16 inches long, and six or eight inches wide. In this way the queens hardly ever fail to get back to their own hives.

About the workers getting mixed, or getting in the wrong hives, and killing queens, that they do go into other hives I have no doubt; but as to their killing queens under such circumstances, I have my doubts; for if such a thing were common, we should have plenty of queenless hives; but we do not have.

Now, friend Root, I am sure that the average bee-man loses very many queens in shaking the combs in handling bees; and I quit that practice, for the reason that I was satisfied I shook many queens outside the hive, and they never got back. I proceed as follows: I raise the cover while my son pours in the smoke. When the bees are well smoked down I raise a comb and hold it with one hand and brush the bees with the other, while my son smokes and brushes the other side (no shaking). In this way there is no turning of the comb, and it is very quickly cleared of bees, and the gentle volume of smoke constantly going over the top of the hive keeps the bees down, and rapid and effectual work is done; as soon as a full comb is taken out an empty one is put in; and thus we proceed from hive to hive, getting over a large number in the least possible time, and no loss of queens, and very few stings.

THE COMB-CART.

I wish Ernest would make and use one. I know he would not be without one again. Do not make it to clear the ground more than about 5 inches; for if you do, when the front or back end rests on the ground there will be danger of the combs slipping one way or the other. Begin loading at the back end, pulling the cart from hive to hive. When full, push it before you and it will astonish you with what perfect ease you can handle 30 combs of honey.

IS FOUL BROOD MORE APT TO AFFECT SOME RACES OF BEES THAN OTHERS?

I most certainly agree with you in your remarks upon J. J. Keith's statement (page 442), where he speaks of foul brood among his Italian bees, and not the blacks; for if there is any difference in the two it is in favor of the yellow bees. I should say that he did not have the virulent foul brood. Once in a great while brood will die in the cell; and one who has not had much experience with foul brood would think it was the simon-pure stuff. I have had two such cases since I have been here in Cuba, and I came to the conclusion that it was the fault of the queen, owing, as I thought, to a constitutional weakness in the queen; and upon removing her and substituting another, the trouble was removed. Let's hear from Prof. Cook upon this matter.

I prefer the beveled-edge hive. I have used both extensively. I would not have the square sides.

A. W. OSBORN.

Havana, Cuba, Apartado 278, June 16, 1887.

Many thanks, friend O. You are hardly a candidate for Blasted Hopes yet, are you? Your yield from 80 colonies was large, not to say enormous—375 lbs. per colony. We should very much like to know what was your greatest yield from any one colony, and about how much said colony in its best days stored in one day. — In regard to the matter of foul brood, we are afraid, as you say, that in large apiaries it is difficult, if not well nigh impossible, to cure the disease in one season. At the present writing, June 22, we are having one or two cases appear daily. This is somewhat better than a week or two ago. — We think it is quite likely that sound hard green wood would work nicely in the Bingham smoker, when it is got well going. We will try it and see. If any one has any better way of using the Bingham or Clark smoker we want to know it. On the other

hand, friend O., I hope you will try sawdust mixed with excelsior, and then stop the nozzle with grass, as described in the issue for June 1, department of Our Own Apiary.

VIRGIN QUEENS.

IS IT ADVISABLE TO DESTROY THEM WHEN 20 DAYS OR MORE OLD?

FRIEND ROOT:—Not presuming to dispute what is laid down in your A B C book, nevertheless your advice to destroy queens that do not lay within 21 days after they are hatched does not agree with my experience. For the past few years, early in March I place my bees on their summer stands from the cellar, and the first warm day after they have had a flight I examine all as to the condition of their stores, keeping a sharp lookout for queenless colonies. I usually find from three to five colonies, out of 50 or 60, that are queenless. I then hunt around until I find a comb with eggs. Out of this I give to each queenless colony a small piece of comb with eggs in it. If the colony is strong enough they seldom fail to raise a queen, but it is then 6 weeks or more before drones are flying. Those queens begin flying soon after drones begin to fly, and prove very fair ones, but never the best, but are about as good or equal to those reared in any other manner artificially. I have watched this matter carefully by examining colonies for drones and drone brood, and I am almost convinced, but not positive, that those queens are 21 days old or more before they are fertilized. Now, friend R., let me stop and tell you, for you are doing a great deal of good that you are unaware of, and may never hear of in this world, not only to me, but to many others. You will say, or think, "There must be some mistake. I don't doubt the queens were probably fertilized long before they began to lay, by drones that escaped your scrutiny, which possibly might be the case, but I am skeptical."

This has been the worst season, up to a week ago, I ever experienced. There is nearly 100 acres of all-sike clover in my locality. It failed to yield honey. I think, because of the long drought last summer and this spring. I was making great expectations, as this was the first season it blossomed. Red clover, for three or four days, gave a good flow of honey—the first crop at that, but my bees were destitute at the time, and barely filled their hives only in the strong colonies. I have noticed before, when red clover is dwarfed it yields honey bountifully, and the bees swarm on it; but when it is so rank they do not notice it—at least, that is the way it acts in this locality.

M. F. TATMAN.

Rossville, Kan., June 20, 1887.

We are always very glad to receive criticisms, or to be corrected, where our statement is apparently wrong, in the A B C of Bee Culture; but, friend T., you and the A B C book do not differ so essentially, after all. If you will read carefully the matter under the head of QUEENS, especially that part under the sub-head, "How Old may a Queen be and still become Fertilized?" p. 202, you will find the following: "I think I would destroy all queens that do not lay at the age of 20 days, if the season, flow of honey, flight of drones, etc., are all right." Notice the last part of the quotation. Dur-

ing certain times of the year, when there are no drones either early in the spring or late in the fall, we sometimes wait two or three weeks, or even a month, before the young queen becomes fertilized. Late in the fall, it is our practice to wait a little longer on young queens than we would where the essential conditions are present; that is, "if the season, flow of honey, flight of drones, etc., are all right."

PROF. COOK IN REGARD TO DRINKING-WATER, SEWAGE, ETC.

HE TELLS US SOMETHING OF HOW GREAT IS THE DANGER.

I DO think you are entirely correct on the drainage, or sewerage question. I should seriously dislike to use water in a well dug wholly in land or ground that was even many feet from a source of contagion. I know of an epidemic of typhoid fever which destroyed two bright young lives last summer, and nearly cut short several more, and clearly from just such a cause. That the germs may be passed through porous soil for a long distance is positively proved. That such germs may also be stored in such soil, constantly threatening life, although their presence is unknown and unsuspected, is equally true. But when a person's constitution, through some lack of vigor, is susceptible, they then lay their fatal grip upon him, and he becomes a victim to these same unwholesome wells. There are two points of vast practical moment. 1. Get water from some stratum which is well underneath a stratum of clay. This may require a deep drive, or bored well. The drive-well patent has now expired. 2. So arrange privy-vaults and other sources of filth and contagion, that the matter shall all go on to the soil and enrich it, and not possibly, by any means, into our wells to poison us. I might add another point: Be sure that no drain can be foul the cellar air, and thus bring diphtheria to our homes. These three points are the first I should look after in entering a new home.

A. J. COOK.

Agricultural College, Mich.

A BEGINNER'S TWO-YEARS' EXPERIENCE.

SOME NOTES FROM A SOUTHERN JOURNALIST; HOW HE KEPT BEES; THE RESULT AND THE MORAL OF THE MATTER.

A BOUT two years ago I became so worn down with editorial and similar work at the desk, having been at it for something like 25 years, that I concluded to stop for a season and take to the "poetry of labor" and try the "catching enthusiasm" of the busy bee. I had often read about bee culture during my editorial career, and, in fact, had a copy of the ABC book, which I received from you some nine years ago for advertising in a newspaper I was then editing and managing. The long-continued and hard work of the kind mentioned had very much worn me down, so that I became at times so weak I could scarcely hold my arms over the desk to examine a newspaper. I frequently had palpitation, and had to take stimulants of some kind, often to enable me to go through the day's work. Being nearly 50

years old, I knew I should not be able to hold out much longer unless I took a rest, and so last October, two years ago, I resigned the position I then held as manager of the advertising department of a large patent-medicine firm, and commenced to read about bees. I bought every book I could get on bee culture, several old volumes of GLEANINGS, and these I read and re-read until I was a walking encyclopedia on bee culture, as I thought. In the winter I procured an old gum of hybrids, bought for Italians; and, having ordered and received hives, and every thing I needed, from A. I. Root, all of which gave the utmost satisfaction, I set about; and, being naturally a mechanic, I placed all the goods, hives, frames, crates, etc., together; and, with the hives neatly set out in our beautiful side yard, 20 x 80 feet, and painted white, the whole, together with neatly arranged vines, flowers, etc., formed a picture of surpassing beauty. I had ten hives and an old gum which I was to transfer to movable frames.

About this time I bought two colonies of Italians in shipping-boxes; and the gentlemen who sold them to me candidly wrote me that two colonies were enough, and that he did not desire to sell me any more. I placed those two colonies in two Simplicity hives, and the gum I transferred, making, as I know now, a rather unworkmanlike job of it; but I was intensely interested in bees, and I intended to make it a success. In fact, the bee-business took possession of me. I could sit by the hives for hours and admire the beauties as they worked, and I never tired in being in the apiary, where I stayed and worked, until, from the pale desk-man, I became as brown and sunburnt as an Indian. But I didn't mind the sun-burning—I was "in for the war," and intended to serve it through and make honey, bees, queens, etc.

Well, the first spring and summer I had to feed those bees through the entire season, adding several swarms, and also four other colonies which I bought. I worked and fed, and looked daily to see the sections filled out with honey; but, alas! they did not fill, and so the season went through without a single section being filled out, and I was out of pocket \$150 for bees and fixtures, and \$25.00 for sugar fed to the bees. Total loss \$175, and a whole year's work gone for nothing, which would have netted me at least \$1800 if I had been working as I did the last year of my desk experience. But notwithstanding all this I did not lose faith in the bees; and when winter came on I packed my favorite hive well, packed partially the others, and so the year closed, as we went into winter quarters.

During the next winter I read and re-read again, and procured several other books on bee culture, determined to make it a success the next season if possible. It is true, I remembered the sweltering days spent in the apiary the year before, as well as the loss; but the thing that I was after was not to be beaten out by my ill success the year previous, and so I reasoned the cause pro and con, and I at last came to the conclusion that the reason of failure last season was not so much that the season was rainy, and then too dry, but that I started with too small colonies, and resolved that the following spring I would "take time by the forelock" and have strong colonies to begin with. Early in February I commenced to feed those colonies, which, with the beginning of the second year, amounted to ten, or at least those which showed that they had

little stores. When the spring opened I had strong colonies all of them—and I can tell you that the way they buzzed over the fences and went for the flowers was pleasant indeed to their keeper. I think I managed them correctly the second year, and the result of this "stick fast" disposition of mine is, that the hives are full of honey, the sections are filled with beautiful combs, and I think that, if nothing happens to prevent, I shall reap as my reward at least one hundred pounds of honey from each colony, and that, too, when we have had two droughts, one which lasted all through the spring, when we had not a particle of rain in nine weeks, and a May and June drought also. I verily believe, that, if we had had an ordinarily good season, I should have made a great deal more money than I did; but I am satisfied with my second year's work; and while it does not pay heavy in dollars and cents, I have reaped a world of pleasure, and my palpitation and weakness have gone. I may say that my health is now very good, and I feel that, with the coming fall, I shall be again ready for almost any kind of work. I have worked two seasons when the thermometer ranged 100 and sometimes 102° in the shade, and when my clothing was wringing wet, through and through; but I found after the work I could then take a bath and feel about as well as ever, and more particularly if I lay down an hour or two after the bath. I may also add, that before this experience I was much troubled with insomnia; but that, too, has vanished, and every night I sleep soundly.

For the benefit of other beginners, and after two years of arduous experience, I will add that I found the greatest satisfaction from the use of wide frames in the second story. I have tried both the crates and the wide frames, and I have noticed that, several times, when I had baited the bees in the crates, they would commence putting honey in the sections in the crates, and for some cause would afterward carry it down, and cease work in the sections altogether. There is still another objection to the crates; and that is, that when it becomes necessary to take out frames of brood to prevent the bees from swarming, and yet to keep the colonies strong, it could not be done with the crates; but with the wide frames these surplus frames of brood could be placed upstairs, and the bees be prevented from swarming, by placing sheets of empty foundation in their places from time to time, and at the same time the colony would be kept rousing strong. With me I had no trouble in getting the bees to work in the wide frames by simply lifting a frame of brood and bees up into the second story, and placing this frame between two wide frames containing sections with foundation starters. For two seasons I noticed that it was much better to use wide frames than the crates, and I shall hold to them until I am convinced to the contrary. It may be true, that in the North, where you have a heavy flow of honey, that the crates may do as well; but they did not work as well with me. I therefore, for reasons stated, consider the wide frames far superior to crates, and more especially with beginners. I think the one fact of being able to use the wide frames in such a way that brood-frames can be placed with them in the upper story, to prevent swarming, and at the same time to keep the colony strong, is a great inducement to use them.

I think after this I shall abandon the bee-business for something that is more profitable. I may keep

a few colonies wherever I happen to be, for my own amusement and instruction, but I do not think it could be made to pay as a regular business in the South, unless one made his own pasturage, for which purpose I have not the land. If I had the land to make the pasturage, or if I were in a honey-country, I would certainly select bee culture as one of the most pleasant of all callings. I truly think it is the most beautiful business in the world.

I have had all sorts of experiences—robbing, uniting, dividing, queen-raising, and some of the queens I raised from the egg now have very large colonies; and withal I must say that, in a busy life of more than forty years, I know of no business that is half as ennobling as working with bees. It is truly "the poetry of labor," and as truly they "teach the art of order to a peopled kingdom." I never again will be entirely without bees.

I can now say, all honor to those who work with the bees. I never knew a bee-keeper but that he was honest, industrious, and loved the works of his Creator. If they are like myself, and I presume the most of them are, they can see much of God in the bees, the flowers, the whisperings of the winds—"sermons in stones, and good in every thing." Certainly, all bee-keepers must, with the Psalmist, often exclaim, "How wonderful are thy works, O Lord!"

T. E. HANBURY.

Atlanta, Ga., June, 1887.

OBSERVATIONS CONCERNING THE EGG-LAYING OF QUEENS.

EXCEPTIONS TO GENERAL RULES.

IN my apiary I have had queens whose eggs produced drones only. They, having deformed or cramped wings, and after many ineffectual efforts, for a week or ten days, to fly, returned to the interior of the hive and commenced to deposit eggs which produced drones alone.

I had one queen, perfect in her appearance, except the right wing was wanting, and that side represented by only a stub next the body, where the wing comes out, that, in some way, became fertilized, or partly so, but she was not very prolific, and I removed her.

I also had in my apiary, several years since, two queens, very prolific layers, but whose eggs produced neither workers nor drones. They would not hatch, but dry up in the cells. I now have a still different case to report from either of the above.

In May, 1886, I had half a dozen or more cells, ten days old, from a favorite queen, which were placed in as many nuclei containing from three to five Langstroth frames, filled with comb honey, and covered with bees. The queen I wish to inform you about now was from one of these cells, placed in a five-frame nuclei. As to outside appearance she was perfect in limb and wing, and of ordinary size. The hive was examined every two or three days, after she emerged from the cell, when the 12th and 14th days were reached without fertilization or the depositing of eggs. The 21st and 22d day came and passed without signs of fertilization. Accepting the Huber theory as regards retarded impregnation, I was satisfied that she would, in a few days, deposit eggs which would produce only drones. I did not examine again until about the 32d or 33d day, when I found the combs well filled with eggs, many hatched, and some larvæ showing several

days' advancement; but a few days later, when the capping commenced, to my astonishment it did not indicate drone brood, but had the flat caps instead of the rounded which are placed over drone brood—whether in drone or worker cells, and on the 21st or 22d day after she commenced laying, as usual the worker bees were appearing. The queen is now in my apiary, a valuable one, and keeps up a ten-frame colony as prolific as if she had met the drones the 6th or 8th day of her life. So this is another exception to the generally accepted rule or theory as regards the fertilization of the queen-bee. The hive was not within ten or twelve feet of any other, and I am well satisfied there was no loss or exchanging of queens, but that she was the identical queen hatched from the cell given in May, and did not lay an egg until she was 27 or 28 days old. I did not notice the evidences of copulation, and can not tell when that took place; but I think it must have been two or three days before she commenced laying.

W. P. HENDERSON.

Murfreesboro, Tenn., June, 1887.

NOTES AND QUERIES.

* DO FIRST SWARMS LEAVE BEFORE THEY HAVE A CAPPED QUEEN-CELL?

HOW about Mr. Doolittle's assertion, that the first swarm of bees never leaves till the queen-cells, or some of them, are capped? With us the exceptions to this rule are very common. I should say that one-third of our first swarms leave before cells are capped. Is this due to locality, or more likely to difference in the strain of bees? Our bees are now largely of Syrian extract, and that may account for the difference. How have others found it? A. J. COOK.

Agricultural College, Mich., June, 1887.

[I believe that, when we had nothing but black bees, the rule given by friend Doolittle used to be pretty certain; but when the Italians came they swarmed quite frequently without any sort of preparation in the way of queen-cells. Perhaps we have not quite understood Mr. D.; for I presume he is as well acquainted with the above facts as almost any one of us.]

EUTOCA VISCIDA.

The plant sent from J. P. Israel, Olivenhain, Cal., is *Eutoca viscida*, Benth. It has no common name.

EXPERIMENT STATION,

Columbus, O., June 11, 1887. Per CRAIG.

LOTS OF HONEY.

We commenced this spring with 12 swarms, and have had 36 now. We had one swarm the 7th of May. Our bees are making lots of honey. We lost 5 swarms.

F. D. SHEPKEY.

Sparta, Mich., June, 1887.

WET WEATHER.

Constant wet weather during the past ten days has caused us a loss of one-fourth of our crop of honey. Colonies have been scarcely self-sustaining yet, and to-day many are dying for want of food—a very unusual thing after June 1.

S. W. MORRISON.

Oxford, Pa., June 8, 1887.

WINTERING BEES IN THE SNOW.

My mode of wintering bees is as follows: Place the hives on some level foundation, and pack them in rows as closely together as possible. Cover them with boards the width of the hive. With the first snow, cover the boards up with snow as much as

possible, and add with each snowfall, until covered to a depth of 3 or 4 feet. They will come out all right in the spring. Any one wanting more particulars about my experience in this covering can address me.

L. H. SPENCER.

Streaton, Ill., June 20, 1887.

[Your plan would probably work all right with you; but with a January thaw, such as most of us have, followed by a cold snap, it might be disastrous to the bees.]

CELERY.

I got one packet of Golden-leaf bleaching celery from Burpee last spring, and I raised the nicest and best I ever saw. I bleached it with boards 12 in. wide. The season was very dry. I ran water between the rows.

WM. ASTRY.

Franklin Square, Col. Co., O., Mar. 8, 1887.

HOW TO GET RID OF BLACK ANTS.

I have found a remedy for black ants that infest hives. It is new to me, but perhaps not to you. It is fine salt sprinkled over them and in the cracks through which they crawl. I have driven away whole nests. Bees are in good condition. There is lots of white clover.

H. STILLINGS.

Boling, Kan., May 24, 1887.

A SUGGESTION ON MILLER'S PLAN OF REMOVING SECTIONS.

I have been looking over Dr. Miller's article in GLEANINGS, on taking sections out of supers. In place of knocking and pounding, why not have a small light lever attached to your table, and when you get your super in place just bear down gently on your super till it drops off? AARON BROGLER.

Jacksboro, Tenn., May 23, 1887.

CLOVER.

Is mammoth clover as good for bees as the common red? We wish to seed 50 or 60 acres to clover—alsike mostly I think, the coming spring.

MRS. J. N. MARTIN.

Pauline, Kan., Jan. 9, 1887.

[Mammoth clover is fully as good as the common red, and I believe it usually yields a good deal more honey, although I believe alsike is generally considered more profitable, when we consider both honey and seed.]

MORE PROOF THAT KING-BIRDS DO NOT SWALLOW BEES.

King-birds do kill bees. They catch them on the wing, and just give them one snap and let the bee fall. It does not look as if they had time to suck the honey, but I believe they do. I have sat in one place and shot seven of those birds without getting off the seat. I have not been pestered with them for two years.

S. TEMPLETON.

Aroma, Ind., May 22, 1887.

MILKWEED POLLEN.

I am in the bee-business, and on reading your book I try to keep posted; but here is something new to me. What this is on my bees I can not tell. They come out of the hive and fall off the alighting-board, crawl around a little and soon die. I send you a few inclosed, to investigate.

A. M. McDONALD.

Blum, Hill Co., Tex., Apr. 26, 1887.

[Why, friend M., your bees have got the milkweed pollen clinging to their legs. Haven't you seen it pictured in the A B C book? The question is, How do they get it in April? There can't be any mistake about it, for it is the veritable saddlebags appendages, so familiar to us every fall. I hardly believe, however, that enough of your bees will die from this cause to produce any great loss.]

LOSSES IN MICHIGAN.

Our bees are doing well. The cold winter took a third of them. But that is not as bad as one of our neighbors suffered. He lost 32 out of 33. Bees are worth \$5.00 a swarm here this spring.

HEBER WALDRON.

Palo, Ionia Co., Mich., May 30, 1887.

HOW TO DISTINGUISH THE BUMBLE-BEES THAT DON'T STING.

In answer to your foot notes, page 182, you can tell the drone bumble-bee by a white spot on the head. When I was a boy, and used the shingle, I could tell them ten feet away. The white spot is square. When I saw one with a square white spot I knew that he could not sting. JOS. FOGARD.

Marion, Ill., Mar. 12, 1887.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

WHAT IS THE TROUBLE WITH THE BEES?

INCLOSE in this a sample of a bee, or of something else, which I find in one of my hives. The colony is hybrid, and strong and healthy. I have referred to all the authorities which I have—the A B C book, Langstroth, the *American Bee Journal*, and GLEANINGS, and all that I have been able to find is a short note on page 439 of the last GLEANINGS, where a man in Georgia has been led to observe the same thing. He says his bees, from ten in the morning till evening, are driving out and killing a bee, in size between a bee and a house-fly, very black, with occasionally the mark of an Italian. The insect that I observe is more like a wasp than a bee, sometimes with one broad band. My opinion is, that they are confined to the hybrids, and that it is caused by introducing or mixing. I should like very much to hear the opinion of our teachers, on the subject.

W. P. ENGLAND.

White Pine, Lycoming Co., Pa., June 8, 1887.

The specimens of bees were received. After carefully examining them and reading your letter, I am strongly of the opinion that, before they hatched, they had been overheated or chilled—more likely the former. It is sometimes a mistake with beginners, when a colony is being robbed badly, to close the entrance up tight, even though in warm weather, and the sun be pouring down hot. The result is, that the bees become almost suffocated, and, in consequence, overheated; the temperature of the brood is, therefore, raised considerably above its normal degree of heat, and what brood is not killed outright will hatch out into small black-looking little bees. Sometimes these bees will hatch out with defective wings, or none at all. Was not the brood in your hive overheated at some time or other, either from the cause that I have mentioned or for some other reason? The reason why the bees were carrying them out was because they were not perfect bees, not having had the proper conditions for healthy growth. Since reading your letter I am strongly inclined to believe that Mr. Bryan (page 439) had this very same trouble. Mr. B. said

that he had been transferring. If the brood had been exposed to the direct rays of the sun for any length of time, it would hatch out with such bees as those you sent.

DOUBLE-POINTED TACKS AS A CONTINUATION OF THE BOTTOM-BAR.

I have a little invention, or convenience, that I have been using for two years in my hives, in the end-bars of my frames—a projection $\frac{1}{2}$ inch from the bottom, a double-pointed tack driven in as

shown in the drawing. B. If you have never used any before, just try a few and report. It is almost impossible to kill a single bee. The bees can in no wise glue the end-bars to the hive. I have seen hives where

half the frames were stuck fast to the end-board. In handling such frames you have to be extremely careful, or you will kill a lot of bees; and when you kill bees it makes the others mad, and I don't blame them. I will use it on my frames as long as I can raise money to buy the tacks.

F. P. HISH.

Henton, Ill., May 21, 1887.

D. A. Jones has the bottom-bar to his frame project beyond the end-bar a little, answering the same purpose of your double-pointed tacks. You will also find the same thing figured in the old back volumes of our bee-journals. The Langstroth hives were at one time all made with a blind-staple driven in exactly as you have it. After using frames in this way, however, almost every bee-keeper who had them sooner or later pulled out the staples and threw them away. The staples themselves killed the bees and bumped the end of the hive when frames were being replaced, and I believe there were other objections.

HOW TO MAKE A SWARM COME OUT BEFORE SUN-DA; DESTROYING DRONE BROOD.

Having a swarm hanging out much, and fearing it might swarm on the Sabbath, I overhauled it and found only several small queen-cells just started. I exchanged a frame of its brood with one having a capped queen-cell, and to my delight it swarmed the next day. I did fear they would destroy the cell on the comb given them; but after the swarm issued I found it all right.

I practice destroying drones in undesirable swarms. This I have done by shaving off the cuppings and heads, as you have suggested. But lately I have driven a dozen or fifteen sharp large tacks through the sole of an old rubber boot. With this I hackle their heads off. This device is better to work in the depressions in the comb. I often find drone larvæ, and for this I have a pepper-box of fine dry salt that I sprinkle them with. It is all very soon thrown out, and generally filled with honey instead of brood again.

S. L. HASKIN.

Waterville, Minn., June 10, 1887.

HONEY-CASES AND T-SUPPORTS.

Having used the T-tin supports for honey-racks many years past, the very beautiful ones you sent me in last order are such an improvement on any I ever made that I am delighted to know that I can

get such. Your zinc-wood honey-boards are also excellent, and used in connection with the T-tin supported honey-case, with long separators, slotted to set down half way in T's, fill all the requirements of a perfect case.

If tin separators are used, and T tins slipped in on top, to correspond with bottom ones, there is no place for propolis, and the wide frame is of no further use. One serious objection to the wide frame is the additional space between brood-nest and sections. The metal honey-board and the wood and metal is a vast improvement on the wood alone, for this reason. J. W. PORTER.

Charlottesville, Va., May 21, 1887.

ALFALFA AND SWEET CLOVER IN UTAH; ITS CLIMATIC PECULIARITIES AS RELATING TO THE WINTERING OF BEES.

Alfalfa, or, as we more commonly call it, lucerne, and sweet clover, are staple grasses with us, and the best honey-producing plants known in this country. Lucerne is just coming in blossom; and the sweet-clover will begin to blossom in about three weeks, so that we shall have no lack of blossoms until frost comes, which is frequently not till October. Sweet clover—the old garden sweet clover when I was a boy—is, in this country, a prevailing weed, growing along all the ditches, and spreading over all the damp untilled corners of the country, and it is rich in honey, continuing to bloom until frost checks its yield.

There has been a good deal said in GLEANINGS in regard to the care and management of bees that does not apply to bees and bee-keepers in this section of the country. For instance, the moth. I have not heard of one here. Wintering is another subject that does not trouble us. Drones were seen last winter in every month, although it is an unusual event. The winter was so mild that it reached far into spring. It is not unusual here to have April weather in February, and then probably have March in May. The great trick in wintering bees here is to keep sufficient honey in store for emergencies like the last winter, and they come more and more frequently. We can not take as much honey in a single season here per swarm, perhaps, as you can, on account of the open winters, when bees fly perhaps every day in the month of January or February, and they must eat the more for that exercise. I would have sent you, according to your wish, the plant I spoke of, that unfolds its blossom as soon as it breaks through the snow, but it would cost me one or two hard days' climbing up and down to do it, and my legs are getting older than they were when I saw the blossoms.

O. B. HUNTINGTON.

Springville, Utah, June 14, 1887.

HOW BRADSTREET MAY BE USED IN SELLING HONEY.

I have sold comb honey in a town of 2500, in Northwest Missouri, for four years, at from 20 cts. at first to 15 cts. this last year. The last sale I made there was at 13 cts., because honey had been shipped in from Kansas City, and sold for California honey; but I know by the style of package it was from Iowa or Missouri. But it could be shipped and sold so low because it was sold through a commission man. I know I could have gotten 15 cts. for the same honey, and not call it a wrong name either. Bee-men, you are to blame for the low prices of honey. The commission man will sell

quick if he sells for two-thirds the value. Why not sell to the retailer direct? My plan is to go to the bank and get the names of a few dealers in good towns from Bradstreet, then write a postal, and state the net price, quality, and quantity, I have ready to ship; state that I guarantee safe arrival by freight, and trust the party for a short time for the pay. I have sold to parties that I never heard of in this way. A better way would be to have the cash before shipping, but I do not think much would be sold so, for a busy dealer will not take time to hunt up your standing. Extracted honey I would sell at home if possible. I will peddle all my honey before sending to commission men. They may do the best they can, but we are the losers.

The season is discouraging; bees are light, and clover dying from drought. I have hopes of a good linn flow, for the trees are covered with buds.

Hopkins, Mo., June 9, 1887. J. C. STEWART—50.

IS IT PRACTICAL TO FILL COMB WITH SYRUP, AND SELL IT AGAIN?

On page 169, March 1st issue, we read an article entitled, "False Statements in Regard to the Honey Business." Now, it may be that I do not understand what is meant by artificial honey; but do you not think melted white sugar, fed to bees, and stored in comb, would be counterfeit, or artificial honey? Or do you think this is never done? Husband and I think that we have known this to be often done. Honey has been brought to our town so white, or so bluish-white, that our bees could make nothing like it, and it was a wonder to me why it was, until I began to read about the counterfeit in the papers, especially the *Tribune*, two years ago.

Lodi, Ohio, Mar. 7, 1887. AUGUSTA MOHLER.

Yes, white-sugar syrup, fed to bees and stored in sections, would be counterfeit honey; at the same time, it could not be called *manufactured* comb honey. While it is possible to fill combs with syrup, it is impracticable. It has been proven, over and over again, that no one can feed syrup to bees, to cause them to store it in sections, and yet make any profit by the operation, at the prices at which first quality of comb honey is now quoted in the market. I feel pretty sure that the honey you saw, with the bluish cast, was genuine honey. Editors of newspapers seem to think that, if sections of comb honey are clean of propolis, bees' legs, and dirt, such as used to accompany the old-fashioned box honey, the honey is necessarily counterfeit. Some of the nicest comb honey that I ever saw, and which I *knew* to be absolutely genuine, had this bluish cast about it. The fact that your bees could not make honey that was bluish white, does not indicate that the combs were filled with syrup to give it this tint. It simply indicates that your locality, and the flora in your section of country, do not afford honey such as will make comb honey look bluish white. Another thing: If honey be left on the hive until it is travel-stained and dirty, it will have a yellowish cast about it. The honey you speak of was probably taken off the hive just as soon as it was capped over.

AN EXPERIMENT WITH A SWARM.

My first swarm came out on the 21st of the present month, and I settled them on a plum-tree and then hived them. It was the largest swarm I ever

saw. I got them all in and moved them to their place at dark, but the next day they all came out again, and I could not induce them to settle. I followed them about a quarter of a mile to the woods, where they settled in a white-oak tree about 50 feet high. I let them stay there about four hours, and then cut the tree, and hived them nicely and that night I brought them home. They went to work right off. I looked them over to-day and found a nice large hybrid queen, so I think they are all right. I have caught 210 drones from the old American hive, which this swarm came out of since it swarmed.

CHARLES WITTER.

Salem, Ind., May 27, 1887.

DANDELION A PEST IN IOWA.

B. Kenyon, of Oakland, Cal., in GLEANINGS for May 15th, inquires about dandelion. You suggest ten colonies to the acre. We have more than ten acres to the colony, and I think our bees would all starve if nothing but dandelion were accessible. With us, dandelion has almost become an intolerable nuisance. It is everywhere. It takes possession of every lawn, every strawberry-patch. It is war to the death to keep it even in subjection. It is open only two or three hours in the forenoon. I wish there were a commercial value on the root, even if not more than a cent a pound. Good wages could be made here at that price. The seeds germinate anywhere, even on a dry tough sod, and in a year or two the roots are down from six to twelve inches. It is the invincible. We have it by the thousands of acres.

DRY WEATHER.

We are suffering from a wonderful drought. My experience of thirty years in Fayette Co., Iowa, has never seen any thing like it. We usually suffer from excessive wet. We have had no rain of any consequence for a year now—only light showers at long intervals. Unless we get rain, the honey-crop must be a failure. Next to dandelion we have white clover. Indeed, in our gardens and strawberry-patches it is a question which shall take possession.

B. F. LITTLE, 107-70.

Brush Creek, Ia., May, 1887.

Friend L., they already make use of dandelion down East, and pay a big price for it besides; but it is not the common dandelion that is a pest in your vicinity. We have sold it to some extent in our town, and it already commands a pretty good figure.

EXPRESS COMPANY REFUSING TO RECEIVE BEES.

It appears that we are about to have trouble in shipping bees. On the 2d inst. I shipped two colonies on the packet to Evansville, Ind., to have them expressed to Michigan. The express agent refused to take them until the clerk guaranteed the payment of expressage. About the same time I had Mr. Hughes, agent here for the boat, to ship one hive to St. Louis, to have it expressed from there to Washington Territory. On the return of the boat to Johnsonville, on this river, the captain received a telegram from the boat agent at St. Louis, which said, "Express refuse bees unless prepaid \$30. See Hughes, Clifton." Under the circumstances I could only instruct the captain to bring the bees back and send the man the \$4.00 paid for them. When the man ordered the one colony he wrote me that he would want ten colonies more if this one was satisfactory when received.

Now, friend Root, can't you and others do some-

thing to help out bee-keepers who have a surplus of bees and can not get rid of them in any other way than to brimstone them? I prepaid ten colonies in hives to Indianapolis, which went through at quite moderate charges. I do not know how we can advertise bees, and agree to prepay the express, as we can not tell where the orders will come from. I have shipped bees to different States, from Nebraska to Maine.

C. WEEKS.

Clifton, Tenn., May 9, 1887.

Friend W., I do not think there need be any apprehension of trouble in the direction you mention. We have for years been obliged to guarantee express charges on bees and every thing else we ship, or else take the risk of delays. In regard to the bees you wanted to ship to Washington Territory, had you asked your agent about it before putting them up he would have told you the charges would be enormous, and would have to be prepaid. We receive orders to ship goods by express every few days, where the result would be disastrous if we undertook to ship as directed.

A SUGGESTION IN REGARD TO THE TREATMENT OF FOUL BROOD, AT THE HOME OF THE HONEY-BEES.

I have just finished reading Our Own Apiary, on page 482. It appears to me, if I understand your treatment of foul-broody swarms, that you destroy all the brood in the infected swarms. Why not save all the brood that will hatch, by giving the brood from two or three infected swarms to one in the same condition, until the brood is hatched, and in this way save a good swarm of bees from the combs of two swarms treated? There can be no danger when honey is coming in, as at present, only a delay of a few days.

L. C. WHITING.

East Saginaw, Mich., June 18, 1887.

Your suggestion might be put successfully in operation under some circumstances; but in our own case, the policy of destroying all the brood as soon as the disease makes itself apparent I think is the wiser one. In the first place, while foul brood exists among our bees, bees are of almost no value whatever to us. Of course, we can not fill orders for bees and queens from the home apiary; and as our locality is already overstocked, we can not run them for honey; so you see our apiary at present, instead of being a source of income, is a source of expense, and the few hatched bees which we might save in the manner you mention would not begin to cover the risks attendant upon such practice. As long as there is a possibility of danger by leaving infected brood anywhere in the apiary, I can not see that it is wise, at least for ourselves, to stack the infected brood in a colony by themselves. Another thing: We have been experimenting lately to determine whether foul brood would ever cure itself. We left some colonies from a week to two weeks; and while the disease apparently disappeared for a time, sooner or later it reappeared. While we were making these experiments we had something like a dozen colonies that were diseased at one time, and which had not been treated. It was easy to observe that foul brood broke out almost everywhere in the apiary during this time. Since

we have adopted the policy of treating the colony immediately, foul brood is now getting to be under our control, and only an occasional colony shows evidences of the malady. The point is, friend W., that, while you have a number of diseased colonies in the apiary, the intermingling of bees from one hive to another is almost sure to carry the infection everywhere; so I think the policy of taking diseased brood-combs, and allowing the bees to hatch out, and putting said brood-combs in a colony by themselves, is as unwise as it is dangerous.

WHY WERE THE QUEENS MISSING?

In March I had 15 colonies of bees (Italians) to put out. They had all wintered well. All swarms appeared to be strong, and had plenty of honey. After they had been on their summer stands about a month I noticed that two of the colonies did not seem to be making the headway that the others were. I examined them and found that they were queenless, with a small patch of brood that might have been 18 days old, and without any queen-cells. Since that time I have lost five more queens, making seven in all. The queens disappeared first, and I think there is hardly a possibility of their having gone out in a swarm. In all cases from 10 to 20 lbs. of sealed honey was left in the hive. What was the cause? After the bees were set out, the weather was mild, the bees flying every day.

Mazomanie, Wis., May 29, 1887. P. F. STICKNEY.

Although I have several times noticed queens disappearing from a good many hives, all at about one time in the spring of the year, I have never been able to account for it. It usually occurs when bees have what is called "spring dwindling," and every thing in the hive seems to be upset, as it were. They almost always die when there is only a small patch of brood in the hives, and not enough bees to cover and care for the brood.

THE DOOLITTLE QUEEN-CELL PROTECTOR.

I came in the house this morning and said to my wife, "Well, Doolittle's queen-cell protector is a daisy—one of the best inventions for a queen-breeder." And I must say I was not a little surprised when, in a few minutes after, I read in the last issue of GLEANINGS of your partial failure. It has worked to perfection in every instance with me. I was very particular in every instance to fit the cell in the apex of the cage, so no bees could get at the side; then I removed one frame from the hive and hung the cage in the space, so it had plenty of room without pressing the cage. Perhaps this was unnecessary. Then I was sure to have the colony or nucleus queenless from 12 to 24 hours before I introduced the cells. I consider it a bonanza.

FRANK A. EATON.

Bluffton, Ohio, June 17, 1887.

Thanks, friend Eaton. We are very glad to receive your report; the more so, because our experiments with the Doolittle queen-cell protector seem to be a partial failure. I can not very well understand now why we did not succeed better. I have this to say, however, that the protectors were tried during a dearth of honey, after apple-bloom and before clover—a time when, above all others, bees seem most disposed to tear down queen-

cells. There were something like two or three dozen queen-cells tried in the protector, and yet out of this number only two hatched successfully. In former seasons we have not had such poor success with queen-cells hatching, even without the protector. It is possible that the peculiarity of the season has much to do with the results; and we don't therefore propose to abandon trying the protector because we at first seemingly failed. We shall give some to Neighbor H., and let him try his hand at it. We hope to give, ere long, a better report, because we feel pretty sure that such a man as Mr. Doolittle would not say it worked successfully unless it did.

DO KING-BIRDS SWALLOW THEIR VICTIMS?

In GLEANINGS of May 15, 1887, p. 395, W. A. Wickham asks the question, "Do king-birds," or, what I have always heard them called, bee-birds, "swallow their victims?" and seems to think they do not. I killed one to-day that had four drones in his crop, but no workers. I killed a frying-size chicken that had 64 drones in its crop, and no worker-bees. In May 1st issue, p. 357, Grant Scofield thinks chickens catch worker-bees. I think that is a mistake. I have noticed them catch drones often, but never a worker. They know the difference as well as we do.

I. T. McCracken.

Rosebud, Ala., June 15, 1887.

Thanks, friend C. While recent reports seem to indicate that king-birds do not swallow their victims, yours goes to prove that they do—at least sometimes. As there seems to be a diversity of opinion in regard to this matter, we should be glad to hear from our readers; that is, do king-birds swallow worker-bees, or do they simply crush them in their bills, extract the nectar, and then cast the robbed victim away? Grant Scofield, to whom you refer, said that, on dissecting the crop of a chicken, he discovered that it had eaten ten times as many workers as drones. The fact that you discovered no workers in the crop of the chicken you dissected does not prove at all that chickens may not sometimes eat worker-bees. It simply proves that *your* chickens did not.

DAMP AND DRY AIR; A WELL THAT TELLS WHEN IT IS GOING TO RAIN.

Some time ago the question was asked, which was heavier—damp air or dry. One of my little boys who reads GLEANINGS to me while I am busy doing other things, said, "Why, pa, if damp air is the heavier, why don't the clouds come down? It must be awful damp up there." Does not the mercury in the barometer rise in fine weather? If it will interest you any, I will give you an account of a singular well that we had that would foretell a change in the weather sooner and more accurately than our barometer, which was a good one too. I have asked many for an explanation of its peculiar action, but could never get any satisfactory answer. I can only explain it by the change in the weight of the air.

Hondo, Texas, March 31, 1887. GEO. E. HAILES.

Friend H., your boy's suggestion seems to be a clincher. You may thank him for me. By all means, tell us about the singular feature of your well. You know we have been discussing wells and the temperature of well-water for some time back.

MYSELF AND MY NEIGHBORS.

Whether therefore ye eat, or drink, or whatsoever ye do, do all to the glory of God.—I. COR. 10:31.

SINCE my last talk to you, my dear friends, I have been learning some lessons: but the memory of those lessons is very pleasant. Satan's evil suggestions seem to have mostly passed away, and in place of them these lessons with pleasant memories come. I am getting *better acquainted* with the small boys than I ever have been before, yet almost all my life I have been much with them and among them. The results of getting acquainted are just like those I have so many times told you about. When we understand each other better, we have better opinions of each other. A few days ago a boy was set to work hoeing weeds out of the strawberries. It was after a rain, and the ground was very soft and mellow, and I don't know how anybody could ask for a nicer job. Why, the work itself is so extremely fascinating that I would go out among the plants, and work after dark as long as I could see, just because I loved to work in the mellow soil, and see the plants grow. I was busy, however, and didn't look after my young friend that morning as I intended to do, and he made very little progress with his work. Satan whispered that any one who would take pay for such a miserable *show* of being busy should be sent home forthwith, without wasting words or any more money in the attempt to make him useful. I was beginning, however, to get a glimpse of these boys' peculiarities and dispositions; and so instead of listening to Satan I went and got a hoe with a great big wheel attached to it. The wheel is as large, or larger, than a good-sized hoop, and it was a very good tool to work with in good ground. I took him off to another field, and told him I wanted him to cultivate the beets with this machine. I found I had made no mistake. The tool suited his boyish spirits, and pretty soon he was all in a glow of perspiration from the violent exercise, and he had accomplished a man's work, and was ready for more of the same kind. I told him I was afraid the work was too hard for him: but he insisted that it was just what he liked. From that time until this he has been a valuable hand, but I have been careful to give him some kind of a job that would enlist his energies and abilities.

A good many times it is desirable to send something after the wagon, that is somewhere on the streets of our town every afternoon. Well, a good many boys would be gone hours, and perhaps come back and not find the wagon at all. One, in fact, wheeled a heavy load around the town from nine o'clock till noon, and did not find the wagon even then. I gave him careful directions and had him try his luck another day; but it was about the same. He hadn't any faculty for finding the wagon, and I had to decide that it was a mistake to send him on such an errand. This same boy, however, did exceedingly well at other kinds of work. Well, we soon found out that the boy who

took such a fancy to the wheel-hoe would find the wagon *any time*, in short meter, and he would do it with very meager directions. When questioned how he always found it so quickly, it was discovered that he had rare observing powers. He is one of the boys who know everybody, and every thing that is going on. We have another boy who will never earn his salt picking peas by the bushel. He is, however, worth almost as much as a man in any kind of work that can be done with horses. He has made friends with one of the biggest and stoutest horses on the place, and he will perform feats with this horse that I would not think of attempting myself. One of them is to take the horse up into the bank-barn and make him turn the wagon around when the horse has only a couple of yards between his fore feet and the edge of the floor over the bay. I would not have permitted him to attempt it had he not been doing it before I knew it. He loves the horse, and the horse has such confidence that he will not get him into trouble that he obeys every word the boy says to him. I hardly need tell you that he governs the horse entirely by kindness, and by constantly appealing to the intelligence of the noble animal. This boy has made me love horses more than I ever loved them before.

A short time ago our people took it into their heads that they wanted me on the school-board again. At first I declared I could not possibly take another burden upon myself; but then, again, came the thought, by accepting the office I might possibly have opportunities for feeding Christ's lambs that I would not have otherwise. I did not think of the text at the head of this talk to-day, but the spirit of it came into my mind, and I decided to accept the call. Very soon it became necessary for us to visit the first primary school; in fact, our large union schoolhouse is beginning to prove too small for the swarms of little ones who are now ready to be taught. I knew the lady who had charge of this department, for she is an earnest Christian, and I had met her several times at our teachers' meetings. Now, I haven't been in a primary school before for a good many years. If the same is true of yourself, my friends, I would advise you to take time and go to school some day with the little folks of the household. There were 52 pupils in her room. They are the same kind of little folks that I often have around me, teasing for a job; in fact, some of them who work for me mornings and evenings were right before me.

The first thing that attracted my attention on coming into the room was, that I did not see any of the tired, wearied looks that I used to see on the faces of small children when it was time for recess, or time for school to be out. These little folks, on the contrary, looked as if they had been having fun, and expected very soon to have some more. I soon decided they were not disappointed either. Miss Smith has made the care of children a study for many years. She not only is conversant with all that has been done, but she has invented some plans of her own to make teaching accord with the

natural restless dispositions of these little folks. They were hardly asked to sit still at all, but at the same time there was such a system about their motions that the school was not a noisy one. Before some little urchin began to feel a disposition to twitch around, the whole school twisted around in regular order, in obedience to some signal from the teacher. Then they stood up; then a little hymn was sung that required them to swing their arms. A great part of the exercises was child's play—yes, a good deal of such child's play as you see going on with the baby, and those a little older. Then they read a few sentences together. To prevent them from getting into a mechanical way of reading the lessons without looking on the book, she had them read backward. Pretty soon she asked who would stand up on the floor and sing for the gentlemen. I thought possibly that three or four among the whole school might volunteer. To my surprise, almost every little hand in the school was raised, and you could see by their faces how they regarded the two who were selected as the *lucky* ones. What pretty little childish songs those were! Children tire very quickly of almost anything. They will pick peas awhile, they will pull weeds awhile, and so on with a great many other things. But if you want them to work well you must change work often. Miss Smith seemed to recognize this, so she had a variety of primers that occasionally took the place of the standard schoolbooks. The primers were wisely edited and wisely chosen, and an involuntary "thank God" welled up as I turned over the one I held in my hand. Thank God, that strong pure-minded men and women were giving their best energies to the work of understanding childish minds, and ministering to childish tastes. What a thrill of joy it gave me to find that Miss Smith was working in the same line I had been, and that she was recognizing, as I had been, that in the care of these little ones we may apply the text, "Inasmuch as ye have done it unto one of the least of these my brethren, ye have done it unto me."

I remember the time when I was required to sit for hours together on a hard bench, without any desk before me, without even a slate and pencil. If I shuffled my little feet so as to make a noise, I was in danger of the master's ruler. My dogs-eared First Reader was the only thing I was permitted to look at, although I had read every page of it until I could almost repeat it off by heart. I had noticed that the little folks who worked for me were always ready to go when it was schooltime. They never seemed to dread going to school. There was an air of cheerfulness I had never understood until I visited that school. I tell you, my friends, that, before those children are ten years old, a foundation will be laid for a good solid Christian character that will go a great way toward shaping the course of their future lives. I am told that like improvements are being inaugurated all over our land. Thank God, that in this land of liberty we are beginning to recognize the importance of commencing with the chil-

dren. Thank God, that the tyranny (and I don't know but it is right to say cruelty) that has been exercised in teaching and managing these little ones is passing away. It seems to me to be a glimpse of the new heaven and new earth that is promised in the Scripture. People give me credit for ability in interesting and keeping busy these little folks. My friends, I don't deserve half the credit in that line that has been accorded to me. I am ashamed of myself when I think of my shortcomings in this direction. By fits and starts I have, perhaps, been trying to take up these tasks for the glory of God; but it is only now and then that I have had glimpses of the possibilities in this direction. It begins to dawn on my understanding now just a little. I am beginning to understand the field unexplored that is contained in the words of the little text at the head of this talk, "Whether therefore ye eat, or drink, or whatsoever ye do, do all to the glory of God." I suppose the latter would include making garden, and hiring the juveniles to catch potato-bugs, transplant celery-plants, pull weeds, etc. I repeat, "Whatsoever ye do, do all to the glory of God." It may be true, there are not many in this world who apply this rule to their every action. It may be true, that humanity has not come up to very great possibilities in this line as yet; but for all that, there are glimpses of what even *one* Christian life might be, that sometimes almost bewilder me. Oh if my poor life could only have more of that spirit in it! Lord, help us! May the great Father help you, my friends, who are hungering and thirsting, and who are longing to see these little ones led in wisdom's ways! Pray for me, that I may do my work better; and while we learn to have a wider and broader charity for small boys who are inclined to shirk over the tasks we give them, may God help us to have a wider and broader charity for *all* humanity, old as well as young!

OUR OWN APIARY.

CONDUCTED BY ERNEST R. ROOT.

APIFUGE.

THOSE who take the *British Bee Journal* have doubtless noticed considerable said in regard to "apifuge." The derivation of the word is from two Latin words—*apis*, meaning bee, and *fugo*, I route, I drive, or I scare. Literally its Anglo-Saxon English name would be "bee-scarer," answering the same purpose, I suppose, as the scarecrow, so familiar to farmers' boys. It is claimed that a few drops of this liquid, sprinkled on the hands and well rubbed over the flesh, will make the bees loth to sting those parts so covered. In other words, they will be so scared that they won't dare to sting. It is even stated by some that it will dispense largely with the use of smoke. My curiosity having been aroused as to the merits of this wonderful stuff, I sent for a couple of bottles of it. A few days ago they arrived. The liquid smells

not unlike wintergreen and tansy ; but whether or not these enter as ingredients, I am not prepared to say.

Well, my hands having been duly smeared with this apifuge as directed, I selected a hybrid colony which had a dash of Cyprian blood in it. I opened the hive, without smoke. As honey was coming in freely, they were not disposed to act very vicious. I placed my hands over the bees, but could not notice that the liquid had any effect. Had they been disposed to sting, as I have seen them sometimes, I do not think they would have hesitated to stick their little weapon into my hands, apifuge or no apifuge. I next poured a few drops of the liquid down among the bees. They immediately sent up a wild humming in the vicinity where the liquid had spattered. Two or three bees received a drop or two. These latter died immediately from the effects of the stuff. I then dropped some of the liquid at the entrance. The incoming bees, laden with honey, as soon as they approached within an inch or two of the alighting-board, hovered about for some little time. After considerable circling they crawled into the entrance. I am convinced of this much: That the liquid is exceedingly offensive to them — that is, before it is dried. I notice that one or two of the correspondents of the *B. B. J.* claim that bees which at first seemed inclined to be hostile, on being presented with the odor of the apifuge became immediately quiet, and seemed to regard the hands of the intruder with kindly intent; and not only that, but the odor was so soothing that the bees apparently *enjoyed* it. I must say, however, that my experience with it is quite different.

When the hands are freshly besmeared with the apifuge, the bees will be repelled to a slight extent; but when the liquid is dried there is no appreciable effect on the bees. I have since tried it in the Swamp Apiary upon some cross hybrids. Did they become quiet under the benign influence of the apifuge? Not at all. On the contrary, I was obliged to start for the smoker. Whatever may be the merits of apifuge, I can not but think that the behavior of the apiarist, and his control of his nerves, has more to do in the prevention of stings than any liquid that can be compounded. If the apifuge has any effect whatever upon the hands of beginners it seems to me it would make them feel more secure, and so give them better control of the nerves.

FLAT-BOTTOM VERSUS NATURAL-BASE FOUNDATION.

There seems to have been a little diversity of opinion in regard to the two makes of foundation as above. By some it is thought that flat-bottom foundation, inasmuch as it is a deviation from nature, is not so economical as the natural base. Our good friend Mr. T. F. Bingham, however, seems to think — or, at least, so expressed it a few months ago to the writer in person — that the flat-bottom foundation, as it had so little side wall, was better for the surplus department; that when the comb, on being drawn out and eaten, the disagreeable

"backbone" could not be detected, or would not be so apparent, as with the natural-base foundation.

A few years ago we made some experiments that seemed to prove then that bees had to waste considerable valuable time in converting the flat-bottom cells into natural-base cells. As we have sold considerable flat-bottom foundation this year, I determined to experiment again, at least on a small scale. As honey was not coming in to any great extent, I selected the strongest hybrid colony we had. I contracted the brood-nest down to only two frames. I am aware that, for general purposes, this is carrying contraction too far; but for my own purpose I desired to have the bees in question store into sections almost every particle of the little honey that they had gathered, in order to induce them to pull out foundation for the purpose above named. Two T supers were prepared and filled with sections, $4\frac{1}{2} \times 4\frac{1}{2} \times 1\frac{1}{4}$, no separators being used. Half of the sections were filled with full sheets of our thinnest flat-bottom foundation. The other half was filled with full sheets of our thinnest natural-base foundation. When the sections were put into the crate they were arranged in alternation, in order that we might the better compare results as the bees began to pull them out. We waited three or four days before honey came in enough for the bees to make any demonstration "upstairs." Just as soon as they did so, however, I watched them closely. Each section having flat-bottom foundation in it was marked with a cross, so that, as the work progressed, I could easily distinguish the kind of foundation which we put in. Some sections were filled out a little in advance of others. Which sections do you think they were? They were those which had no cross-marks on the tops (natural base). Although the sections bearing the crosses had an equal advantage with those next to them, the bees, instead of pulling out the flat-bottom foundation immediately, tore holes in it and remodeled the base before they attempted to draw it out. This consumed considerable time, and the result showed quite plainly that the bees would convert into comb, in less time, foundation having a natural base than foundation having flat bottom. A second examination has confirmed me in all the above statements.

It may be, however, that, if I had the opportunity of conducting the experiment on a larger scale, I might see little if any difference in favor of either; at all events, Dr. C. C. Miller, having purchased some 50 lbs. of the flat-bottom foundation, has this same matter under experiment, if I am correct.

HOW TO HANDLE SECTIONS FILLED WITH HONEY.

During Dr. Miller's late visit, among other little hints that he spoke of in connection with our pursuit he mentioned a little trick in handling sections filled with honey, so as to pick them up rapidly, and yet with entire safety to the nice and evenly filled combs. From the engraving on next page, the reader will catch the idea.

METHOD OF HANDLING SECTIONS.

Grasp the two sections, placed as seen in the engraving, in such a way that the thumb and finger cover the two upper corners adjacent to each other. You will observe that you can thus with one hand pick up two sections; and as you proceed to put them to one side, the two pairs may be placed together compactly. This method of picking up sections is, perhaps, in common use among not a few of our readers; but among some of the friends, especially beginners, the idea may prevent them from damaging the sale of otherwise marketable honey.

FOUL BROOD.

Our old friend the enemy is still with us, and does not seem disposed to give us any rest this season. We are still experimenting on different methods of cure. We have now under experiment the plan recommended by C. F. Muth, of Cincinnati — that is, to spray the combs with salicylic acid in solution. As yet we have not reached any definite conclusion in regard to it. We have also under contemplation Frank Cheshire's phenol cure. There are so many factors which must be taken into consideration, and which, in spite of us, seem determined to upset our efforts in getting exact results, that we will not report just at present.

FOUL BROOD, BY A. I. ROOT.

ALSO SOMETHING IN REGARD TO PUTTING UP AND SHIPPING BEES BY THE POUND.

THE friends will notice, perhaps, that Ernest has told all about foul brood in our apiary; and he has covered the ground so well that I have but a single point to make. It is this: Although we have been at work nearly a year with this pestilence, there has at no time been more than a few cells of foul brood in a comb. Most cases that we have treated by fire have had only from three or four to a dozen cells in the hive. In fact, all the foul brood that has been in our apiary has done no damage practically whatever. Our colonies are strong, healthy, and prosperous. They had never wintered so well in the world as last winter. One might ask, "What is the use of making all this fuss for nothing?" I reply, "Only that we may by no

possibility send foul brood to any of the rest of you." Finding only two or three cells in the Swamp Apiary was enough to condemn it, so far as using the bees to fill orders was concerned. When we succeed in stopping this occasional breaking-out of it we may accomplish something of benefit to the world. From what I have seen of it, I think it quite likely that it might be a *considerable time* before it produces any effect so far as honey-gathering is concerned at all.

If we use none of our bees and queens, how, then, do we fill orders? Well, the responsibility fell first on Neighbor H., whose apiaries are several miles distant. When we began to draw on his apiaries, however, until they seemed in danger of ruining his stock by taking away too many bees, we were obliged to hunt up nice stock among our neighbors. He found a place a few miles away, where there were nice bees, originally from our own stock, and I asked him to give an account of his trip, which he does as follows:

D. L. JONES'S APIARY; THE ROADS, ETC.

After making many promises to visit Jones's apiary (not D. A. Jones, of Canada, but D. L. Jones, of Le Roy, O.), I started with a buggy full of bee-cages, and about the time I started it began to rain; and as the honest farmers had been working out their tax due the State of Ohio, when it was so wet that they could not work anywhere else, I had the full benefit of our new system of road-making. I found a nice pile of sods scraped up in the center of the road, that looked like a row prepared to set out sweet potato plants. As I had but one horse it was impossible to drive in the center of the road. I had to go on one side, with two wheels on the ridge and two in the ditch, with one side of the buggy two feet higher than the other. Don't do so any more, brother farmers of the State of Ohio. We can afford to be cheated out of the tax, better than the suffering public can afford to bump over the roads after you have scraped sods in them.

But I got there after a while, and found an apiary of 37 colonies of nice bright Italians. The hives were in three rows, on a well-kept lawn, and so full of bees that it was nothing but fun to put up pounds of bees. I got to work just as the noon whistle blew, and at 15 minutes past one I had 25 pounds of bees and 12 queens tacked up in 23 separate cages.

This is the moral that Bro. Root wants you to draw from this story: That, with the modern appliances for handling bees it does not take long to weigh and put up quite a good many orders, provided you have the bees and the tools to do it with.

H. B. HARRINGTON.

Medina, O., June 20, 1887.

There is just one point I wish to make in Neighbor H.'s communication above. Some years ago Mr. H. A. Burch gave as a reason for not filling his orders, that he had so many of them he could not get around to all his business, and it was out of the question to find competent help to put up the bees and send them off. Mr. Horn has lately made the same or a similar plea. Now, I do not want to be uncharitable, but I can not understand how any man could ever be swamped by having too much business, especially business where he gets cash before

he sends off his goods. Now, then, to the point: Neighbor H. drove several miles away from home, jumped out of his buggy, put up 23 separate packages of bees containing queens, and did it all in 75 minutes. I do not believe I could do half as well as that myself. You see, he had to open the hives, hunt the queens, shake the bees from the combs, weigh out the required amount, be sure the queens were put in, then close up the hive. Simplicity hives and metal-cornered frames were probably a large factor in enabling him to do this. Suppose, now, a man should have such a run of business that he had four or five hundred dollars' worth of orders for bees and queens on hand at once. How long would it take him to fill them all, providing he had the bees and queens from which to fill orders? The above also speaks well for the cages, tunnel, and other arrangements that I invented several years ago for the purpose of making this kind of buying and selling possible. The 23 cages of bees which he put up in an hour and a quarter are worth over \$50, at our regular retail prices.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER,
MEDINA, OHIO.

TERMS: \$1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, JULY 1, 1887.

Blessed is the man unto whom the Lord imputeth not iniquity, and in whose spirit there is no guile. PSALM 32:2.

OUR subscription-list now numbers 7491, a gain of 177 within the last month. Thanks.

GLEANINGS AS AN ADVERTISING MEDIUM.

We are pleased to append the following from one of our advertisers. With our large and increasing subscription-list, a responsible advertiser, who offers good goods at reasonable prices, can hardly fail to bring some sort of return. If you do not hear from your adv't, either your goods are not in demand or the price is too high.

The little advertisement in GLEANINGS of June 1st brought me orders for queens from ten States—Pennsylvania, New York, Virginia, New Jersey, Michigan, Illinois, Iowa, Kansas, Nebraska, and Ohio, and I have been compelled to send some queens that I did not wish to, and could not well afford to, in order to fill orders. It seems that, from the orders received, GLEANINGS is a good advertising medium. Please announce that I have no more queens at present. ELIAS COLE.
Ashley, Ohio, June 24, 1887.

WATERBURY WATCHES—A NEW ARRANGEMENT.

THE manufacturers have recently decided not to allow anybody to offer Waterbury watches as premiums for getting up clubs, or for any other purpose. The new arrangement is, that all Waterbury watches shall be sold for \$2.50 each, no more, no less. This is to be the price of one or the price of a hundred. Bona-fide dealers in watches get wholesale prices, as a matter of course; but all dealers are to buy of the factory direct, and no middlemen. The watch, in its recently perfected

state, is simply a wonder for the insignificant price of \$2.50. For my own use as a timepiece I would rather have it than any watch I ever before carried, at any price, and I have carried watches that cost \$100 or more. All the Waterbury watches we sell are tested by myself individually, by carrying each watch in my pocket one whole 24 hours.

THE HONEY-CROP FOR 1887.

At this writing, June 30, the entire yield from white clover has been a little more than enough to keep up brood-rearing; and reports from other localities are, as a rule, a good deal the same. Basswood opened a little earlier, and is now nearly in its height, and honey is coming in fairly; but it is hardly probable there will be a full crop in many localities. In view of this I think I would not be in haste to get rid of nice honey.

JAPANESE BUCKWHEAT.

Now is the time to sow buckwheat for grain and for honey, in most localities. It is true, it can be sown later, and give a crop of grain if the frost holds off; but it is always more or less risky. Better get it in some time in July, if you can. We have an acre of the Japanese that is looking beautiful now in the morning sun. The first leaves are about the size of a quarter-dollar, and the piece, to me, is a thing of beauty when I first get up in the morning. We have secured another lot of the seed, and can furnish it at the prices given in our issue of June 1, page 447. Buckwheat does nicely on ground where early potatoes have been dug. Every bee-keeper should test his locality for buckwheat, and I think it will pay him to make a small test of all the different varieties. Buckwheat can almost always be got in on land from which a crop has just been taken, so it costs comparatively nothing, except preparing the soil and sowing the seed. With us it pays to make the ground rich, and work it up extremely fine.

MR. THOMAS HORN.

I DO not see but that we shall be obliged to have an article with the above heading in every issue for some time to come. I hope, however, the articles may grow shorter and shorter. As we go to press, not one single individual has written us that he has received a note from Mr. Horn. A letter from his vicinity, however, informs us he has had bad luck, and left the place to hunt for work. We might have supposed that Mr. Horn meant to be straightforward and square, but was simply unfortunate. His recent positive statement, however, to the effect he had sent notes to all he was owing, when he hadn't sent any note at all, seems to indicate he is not now (if he ever has been) even a truthful man. This seems to put rather another phase on the matter of first receiving the advertisement of a dishonest man and a swindler. In that view of the case I feel as if I ought to make some arrangement with the friends who have lost by sending him orders. It may be well, however, to wait a little. Meanwhile, is it indeed true that not one of you, my friends, have received even a note from Mr. Horn?

MR. K. P. KIDDER.

WE have had quite a few inquiries in regard to the standing and responsibility of this gentleman; but I am glad to say that we have had no complaints from any one who has ever sent to him for goods. Many of his advertisements, however, promise a good deal for only a small sum of money.

We have sent him the money once or twice, to see whether his goods came up to representation. The money was returned, saying he was at present out of the article. The advertisement below we find in the *Farm and Fireside*, Springfield, O.

TWO THOUSAND DOLLARS A YEAR KEEPING BEES on new plan, and no stings. Also, how to raise good pork at 2 cts. a pound, net, without grain. Particulars sent free. Address K. P. KIDDER, Burlington, Vt.

The heading is, as you must admit, exceedingly taking, and we wrote at once and asked Mr. Kidder to please give us further particulars; and as the pork we raise costs us quite a bit more than 2 cts. a pound, we are quite anxious to learn all about the new plan. Up to date, however, no reply has come to hand. Have any of our readers been more successful?

IS THE BEE-STING USED FOR ANY OTHER PURPOSE THAN AS A WEAPON OF DEFENSE?

Our good friend M. H. Tweed, of Allegheny City, Pa., sends us the following, clipped from the *Pittsburg Chronicle* of June 7:

At a meeting of the Physiological Society of Berlin, it was given out as a fact, that when the bee has filled his cell, and has completed the lid, a drop of formic acid, obtained from the poison-bag connected with the sting, is added to the honey by perforating the lid with the sting. This formic acid preserves honey and every other sugar solution from fermentation. Most of the insects that have a stinging apparatus similar to that of bees are collectors and storers of honey, so that the sting has a double function—it is a weapon and a pickle.

We are not much acquainted with the Physiological Society of Berlin, but it seems to me they had better be sure their facts are facts before they give them out. The item above will probably have some such a run as did Prof. Wylie's "scientific pleasantry;" but until somebody can give us some positive facts, gleaned from direct observation, we shall refuse to believe that honey needs to be pickled, and that the bees use their stings to pickle it before it will keep without fermentation in the hive.

STILL ANOTHER BEE-BOOK.

WE have just received from Ivar S. Young, of Christiana, Norway, a copy of his work on bee culture, entitled "Practical Manual of Bee Culture." The book contains 100 pages, 5x6 inches in size, German type. The printing is exquisitely beautiful—in fact, the best we have seen in any bee-book, with the exception of Frank Cheshire's. In the book there are 61 cuts of the highest order of engraving, printed to correspond. Those representing the different parts of the bee; as well as those showing parts of bee-plants, are beautiful indeed. One thing which seems odd to American bee-keepers is the "heavy part" which straw plays in the apiculture of Europe, even as far north as those countries intersected by the Arctic circle. On the other hand, some of the most universally adopted principles of American apiculture are alluded to by our European friends more as things of curiosity than as something demanding serious attention. In one respect, however, we think they are far behind the age; and that is, in the use of the tobacco-pipe while handling swarms of bees. Here, at least, we are sure tobacco is a detriment; and would it not be just as well, friends, not to go to the expense of engraving so useless an appendage, even though you should prefer to use it while working in the apiary? The price of the book is not stated. The language is Norwegian.

BEES AND FLIES ON THE WINDOWS.

My friend, are there any dead bees or dead flies lying on the sill of any of your windows, in the house, garret, down cellar, on the window of your

honey-house, the windows of your shop, barn, or any out-buildings that contain windows? If so, let me tell you that it is against the laws of God, if not the laws of man, to let the little creatures die thus, when the matter is so simply remedied. Raise the window just enough so the bees can creep under the lower edge of the sash, and they will get out themselves. The same is true of flies. A great many times I have seen big green flies spotting and soiling the windows badly, when just a little aperture at the bottom of the sash would let them out into the open air. Why, it is a pleasure to me to raise the windows just a little, and let the bees, flies, and other insects shoot out and enjoy their God-given liberty. Another thing, it is painfully untidy to me to see dead insects accumulating on window-sills. I presume that, as a matter of course, a good wife will take care of the windows in the house unless it is some room that you claim especially for your own. But please do take time enough yourself to see to the other buildings I have mentioned. When I go into any of the rooms of our factory, and see a great lot of bees on the window-sill that have buzzed themselves to death while big men and women stood right near day after day, who could not take time or thought enough to let them out, it has almost made me feel indignant. I try to attend to all of these things; but sometimes when we have severe storms it is necessary to shut the windows clear down, and after that nobody seems to take pains to open them unless I see to it personally. Now take a careful look, will you? and see if there are any windows that are murdering and torturing God's creatures in your vicinity. As a matter of dollars and cents it will also pay you, for it is a great deal cheaper to let out the insects than it is to scrub off the stains that they make on the glass; for I suppose every window gets scrubbed once in a year or two, (?) if not oftener.

SPECIAL NOTICES.

HONEY-JUMBLES.

THE last ten barrels of these delicious cakes for lunch are greatly superior to anything we have had heretofore. The manufacturers seem to have beaten themselves this time. As tasting is, however, much ahead of any description, we will send a dozen by mail, as samples, on receipt of 20 cts. If you want more, you can have a whole barrel for an even \$5.00.

FULL COLONIES AND NUCLEI AT GREATLY REDUCED PRICES.

THE bees and nuclei referred to on page 347, issue for June 1, will be sold during this month at a discount of 10 per cent from prices given there. This will make a full colony of full-blooded Italians for only \$4.50, and a two-frame nucleus, tested queen, \$1.80. Surely they should all go off at these prices where anybody is in want of bees. Remember, this offer is only on this special lot, to be shipped from Quitman, Nodaway Co., Mo. We guarantee them to be fully up to representation.

CIRCULARS RECEIVED.

The following have sent us their price lists:

Stair & Cather, Ashville, Ala., send us a 4-page list of Italian queens.

H. H. Brown, Light Street, Pa., sends us his list of queens, bees, foundation, etc.

J. H. Howard, Holme, England, sends us two catalogues of every thing pertaining to bee culture. They are very attractively printed, one being lithographed.

TOBACCO COLUMN.

TOBACCO AND THE HONEY-TRADE; FALSEHOOD VERSUS TRUTH.

I HAVE taken much interest in your Tobacco Column. If our papers over the country generally were as ready to publish such solid truths in regard to the evil effects of tobacco, and keep them before their readers as they are the slanderous report about the manufacturing of artificial honey, they would confer an everlasting blessing upon mankind and womankind. I say womankind, because, with us, the snuff-box with very many of the women is as indispensable as tobacco in its other forms is with most of the men. Surely, if more such stubborn facts as given in this timely piece were known throughout the land there would be a wonderful let-up in the use of this vile stuff. On the other hand, so much has been said of late about the adulteration of honey, that, again and again, right in our little town of Uvalde, where honey is comparatively cheap (extracted 5 to 7 cts.), and sugar high, about 10 cts. per lb., have I heard my brother bee-keepers accused of selling "nothing but sugar" for extracted honey, and no doubt the same has often been said of me. Last fall I found much difficulty in trying to sell nice white section honey among the people in a neighboring city, put up in the 12-lb. Heddon shipping-crates bought of you, simply because many of them thought it impossible for the bees to do such work, and that surely it must be some of that manufactured honey they had so often read about. It is useless to tell them what any sane person ought to know, that we can't afford to buy sugar for 10 cts. and sell it for 7, or that A. I. Root, one of the largest bee-supply men in the world, has a standing offer of \$1000 to any person who will just show him the place where comb honey is manufactured. What a power is the press! and if it would only take up the refrain of GLEANINGS' Tobacco Column, what a revolution would in time spread over our mighty land! Allow me also to commend GLEANINGS for its many timely articles devoted to our health and homes.

Uvalde, Texas, May 24, 1887. J. D. FELIX.

Be of good cheer, friend F. I know how foolishly stubborn the world seems to be in this matter of the adulteration of honey; but light is breaking, and intelligent people are beginning to rebuke these slanderous falsehoods whenever they are heard.

THE EVIL TENDENCIES OF TOBACCO ILLUSTRATED. HOW ONE VICE LEADS TO ANOTHER.

I have been a user of tobacco for about one year steady, and four years off and on. I tried to quit several times, but my appetite for the weed overcame the desire to quit its use. My eyes soon began to hurt, and I lost 10 lbs. in weight in less than a month, and I never felt well. This feeling made me want stronger stimulants, and I took to drinking whisky, and going to dance parties. I stopped going to church and all religious worship, and was going down hill as fast as I could go. About April 13th I went to prayer-meeting and was convicted of my sin. I went home deeply troubled. My troubles lasted all next day; but a little after night, when in my room, something seemed to whisper, "This may be your last chance; heed not the call, and the door may be closed for ever." 'Twas then I

fell on my knees and prayed, "Father, forgive me. I have sinned." Relief came to my troubled soul, and I arose from my knees a new man at heart. I then determined to give up the use of a thing that cost me so much. I have been without the weed for nearly two months, and I have now not much longing for the stuff.

Mason, Texas, May 7, 1887. A. H. AUSTEN.

A neighbor bee-keeper of mine came in the other day to buy some queens. When about to leave he said, "I have quit chewing tobacco. I have not taken a chew in three weeks, and I have been a constant user of it for over fifty years. With God's grace to sustain me, I do not expect to use it any more."

"And you will pay for a smoker if you do?" I said.

"I will," he replied.

Please send him a smoker and a copy of GLEANINGS that you put this in, to David Hughes, Hackberry, Lavaca Co., Tex. J. K. MULLIN.

Oakland, Texas, May 9, 1887.

I have been chewing tobacco, but have quit. If I ever chew or smoke again, I will send you 70 cents for the smoker.

F. L. SUFFERN.

Voorhies, Ill., April 19, 1887.

I have quit the use of tobacco, and will never use it again. If I ever use it again I will pay for the smoker.

J. W. TRIBBLE.

Prescott, Ark., May 5, 1887.

If your offer of a smoker holds good to non-subscribers, please send one, as I promise to abstain from the use of tobacco, and to pay for the smoker if I use it again. THEO. B. HENDRICKSON.

Springdale, Pa., May 16, 1887.

JOINING THE RANKS OF MANY.

I have been a smoker ever since childhood; and seeing so many giving up the habit I will say that I promise to quit; and if ever I smoke again I will pay you for smoker you send.

W. V. JOHNSON.

Fairmount, Ark., April 13, 1887.

As I am in the apiary business, and have been an inveterate smoker of the weed, I claim a smoker of you. I promise I will never use the poison again; but if I do I will pay you your price in full for the smoker.

J. B. MAYO, M. D.

Bear, Montgomery Co., Ark., Apr. 12, 1887.

THE BOY WHO SIGNED THE PLEDGE.

I am the boy you gave the smoker to, and am 14 years old. I signed your pledge last fall and I have kept it. I will try to get some more boys who chew tobacco to sign the pledge if I can.

R. REED.

Jolietville, Ind., June 2, 1887.

I think you are the means of doing a great amount of good as a reformer. My brother has stopped smoking. Will you send me a smoker? He desires it to be sent to me. If he ever smokes again I will pay for the smoker.

Prairie City, Ill., May 7, 1887. CORA A. CASTLE.

QUIT USING AT 51 YEARS OF AGE.

You may send a smoker to Thos. Harden. He has quit using the weed, at 51 years of age, so I think he deserves one to strengthen his resolution. If he resumes I'll see that you get your pay. Our bees are storing honey rapidly.

MRS. MAGGIE GOODRICH.

Rock Falls, Tex., May 4, 1887.

Wants or Exchange Department.

Notices will be inserted under this head at one-half our usual rates. All ads intended for this department must not exceed 5 lines, and you must say you want your ad. in this department, or we will not be responsible for any error. You can have the notice as many lines as you please; but all over five lines will cost you according to our regular rates. Of course, this department is intended only for bona-fide exchanges.

WANTED.—To exchange, hives, sections, frames, crates, etc. (either flat or nailed), for white paint, box nails, foundation, belting, or any thing I can use. Send for free catalogue. 9-11-13d
C. W. COSTELLO, Waterboro, Me.

EGGS for hatching.—Wyandottes, Polands, Hamburgs, and Leghorns, in exchange for section boxes, or foundation. Circulars free.
4tfdb. A. H. DUFF, Creighton, Ohio.

WANTED.—To exchange English lop-ear rabbits, Guinea pigs, and water-spaniel dog pups for bees by the pound. F. GROSSMAN,
11tfdb Kammis, Cuyahoga Co., O.

WANTED.—To exchange a "Star" bicycle for bees. Just the horse for a bee-keeper. 1213d
Box 375. C. H. SMITH, Pittsfield, Mass.

WANTED.—To exchange Italian and hybrid bees in Simplicity hives for a first-class 50-inch bicycle. D. S. BASSETT,
12tfdb Farnumsville, Wor. Co., Mass.

WANTED.—To exchange 1 organett, 1 German accordion, for bees by the pound, or full colony. Make offers, and address S. F. REED,
13tfdb N. Dorchester, N. H.

WANTED.—I will exchange tested or untested purely bred Italian queens for a microscope or telescope. A. P. STAIR,
13d Whitney, St. Clair Co., Ala.

WANTED.—To exchange for 3-frame nuclei with tested queen, pure Italians or Holy-Land bees, one 6-inch Pelham foundation mill, complete, with dipping-tank. Give prices of bees.
13d Address F. THIELE, Caroline, Wis.

WANTED.—To exchange a bee-keeper's complete printing outfit, for a Barnes hand-power circular rip saw, Barnes foot lathe, or any thing useful of equal value. M. W. SHEPHERD,
13d Rochester, Lorain Co., Ohio.

WANTED.—A situation in some apiary; 10 years' practical experience in bee culture. Guarantee satisfaction in my work.
13d L. WERNER, Edwardville, Ill.

FOR SALE CHEAP!

25 colonies of Italian bees in 8-frame hives, L. frame, with untested queen, \$5.00 each; tested queen, \$5.50; with hybrid queen, \$4.50. Two-frame nuclei with untested queen, \$2.00 each. The bees are in good condition. Also my 8-frame hive for comb honey, complete hive, or arranged for comb honey, including body, bottom-board, ½-story cover, 8 brood-frames, 1 section case, 1 sink honey-board, all complete, no paint, for only \$1.40. 13d
J. M. KINZIE, Rochester, Oakland Co., Mich.

UNTESTED ITALIAN QUEENS.

Single queen 65 cts.; 5 for \$3.00; 12 for \$6.50. Bees per pound, same price. I. R. GOOD,
13tfdb Nappanee, Ind.

FOR SALE

An 80-acre farm in Franklin Co., Ill. About 60 acres in cultivation, 2 good wells, ½ mile from school, 3 miles from P. O., ½ mile from Co. seat. For particulars as to price, address John W. Lillie, Ewing College, Ill., or to me here. 13tfdb
JOHN A. LILLIE, Raton, Colfax Co., N. Mex.

DADANT'S FOUNDATION FACTORY, WHOLESALE AND RETAIL. See advertisement in another column.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough to these queens to pay for buying them up and keeping them in stock; and yet it is oftentimes quite an accommodation to those who can not afford higher-priced ones.

I have some fine mismated Italian queens from imported mothers, to sell at 50 cts. each, and guarantee safe arrival. W. A. SANDERS,
Oak Bower, Hart Co., Ga.

I have a lot of hybrid and mismated Italian queens that I will sell at 40 cts. each, or 3 for \$1.00. J. M. KINZIE, Rochester, Oakland Co., Mich.

I am requesting my apiary of Italian bees, and will sell queens at 50 cents apiece. Satisfaction and safe arrival guaranteed. HARRY G. CAMP,
Winona, Col. Co., O.

I have ten good hybrid queens for sale at 50 cts. each; five to one address, \$2.00. I will also sell virgin Italian and hybrid queens at twenty-five and fifteen cents each. W. E. MORRISON,
Alvinston, Ont., Can.

I will sell black queens for 25 cents and hybrids for 40 cents, by return mail. Wings clipped, and raised in 1886. GEO. L. FERRIS,
Five Corners, Cay. Co., N. Y.

BLACK AND HYBRID QUEENS FOR SALE.—Black, 25 cents; hybrid, 40 cents; mismated, 45 cents.
W. G. HAYEN, Pleasant Mound, Ill.

Pure Italian Bees & Queens for Sale.

Untested queens, 75 cents each; 3 for \$2.00. Tested queens, \$1.50 each; 3 for \$4.00. Full colony in Simplicity hive, \$5.00. Three-frame nucleus with untested queen, \$2.00; with tested queen, \$2.50. Safe arrival guaranteed. If you think they are not pure, send your address and I will send you a sample. Queens for sale in July and August. Address or call on 13d BEN. J. COLE, Reno, Wash. Co., O.

Bees at Living Prices.

Pure Italians and hybrids with untested queen, \$1.25 per pound; with tested queen, \$1.75 per pound. Send for price list. W. S. DORMAN,
13d Mechanicsville, Iowa.

ITALIAN QUEENS.

Reared from one of A. I. Root's very best six-dollar selected tested imported queens, and from the purest and best of home-bred queens, and the cells built and hatched in full colonies. Warranted queens, \$1.00; five for \$4.00. Warranted queens reared by natural swarming, \$1.50; two for \$2.50; tested queens, \$1.25. Selected tested queens, reared by natural swarming to breed from, \$2.50. Safe arrival and satisfaction guaranteed. Remit by registered letter or money order, payable at Salem, O. 13d
F. H. SCATTERGOOD, P. M., Winona, O.

UNTIL FURTHER NOTICE

I will sell select tested Italian queens at \$1.00 each, by return mail *prompt*. Satisfaction guaranteed. 13d WALTER S. POWDER, Grosbeck, Ham. Co., O.

THE NEBRASKA APIARY.

3-frame nucleus hybrid bees (all fra's containing brood) with queens, \$2.25; full colonies of bees in one-story 10-fr. Simp. hives, \$5.50; chaff hives (see in cut of apiary, Apr. 15th GLEANINGS), \$2.50; two-story Simp. hives set up all complete and well painted, \$1.75; 4¼x4¼ V-grooved sec. (less than 500, ½ ct. each); per M. \$4.50. Photo of apiary "to boot" on cash orders of \$5.00 and over. J. M. YOUNG,
13tfdb Rock Bluffs, Cass Co., Neb.

PASTEBOARD BOXES

FOR ONE-POUND SECTIONS OF

COMB HONEY.

This box has a bit of "red tape" attached to it to carry it by. It makes a safe package for a single section of honey for the consumer to carry, or it can be packed in a trunk, if he wants. It can be opened in an instant. The price of the box is 2 cts. each, set up; in the flat, 15 cts. for 10; package of 25, 30 cts.; \$1.00 per 100; or \$9.00 per 1000; 10,000, \$80. If wanted by mail, add \$1.00 per hundred for postage. Colored lithograph labels for putting on the sides, two kinds, one for each side, \$3.00 per 1000. A package of 25, labeled on both sides, as above, 50 cts. By mail, 30 cts. more. They can be sold, labeled on one side or both sides, of course. We have only one size in stock, for Simplicity sections. Sample by mail, with a label on each side, 5 cts. If you want them shipped in the flat, labels already pasted on, the price will be ten cents per hundred for putting them on.

Your name and address, and the kind of honey, may be printed on these labels, the same as other labels. The charge for so doing will be 30 cts. per 100; 250, 50 cts.; 500, 75 cts.; 1000, \$1.00.

A. I. ROOT, Medina, Ohio.

FOLDING BOXES.

Our Carbons for enclosing Section Honey are the best & lowest priced in the market. Made in one piece. With or without Tape Handles. With Mica Fronts or without. In the Flat or set up. Printed or not. Any way to suit. We are bound to satisfy you. We have just put in special Machinery for their manufacture and are prepared to fill orders promptly. Price List Free. Samples 5c.

14 oz. Glass Jars \$5.25 per gross, including Corks & Labels. 1-1/2 & 2 gross in a Case, Catalogue of Honey Labels free.

W. Z. HUTCHINSON,

ROGERSVILLE, GENESEE CO., MICH.,

DESIRES to call attention to the typographical neatness and "get up" of his little book,

"THE PRODUCTION OF COMB HONEY."

It is printed from new type (brevier); the matter leaded; the paper is heavy, delicately tinted and super-calendered; and the press-work is a "credit to the craft." But it is the cover, which is bright-yellow card-board, passed through a comb-foundational mill, that has brought forth the most enthusiastic encomiums. The work is very nicely done, and, at the first glance, the cover would almost be taken for foundation; while the beautiful twig of basswood upon the back of the cover and the artistic lettering upon the front, printed as they are upon a corrugated surface—all combine to give the book a peculiarly neat and tasty appearance.

Dr. A. B. Mason writes:—The cover is nice, printing fine, and contents grand.

Dr. C. C. Miller says:—Nothing less than a genius would have gotten up that cover.

E. Kretschmer says:—It is a surprise, in style and workmanship. Nothing could be added to improve it.

Louis Werner writes:—It is the best bee-book I ever had, and I do not see how you can print such a neat book for so small a price.

James Heddon writes:—Your book is a "dandy." The "get up" is nowhere equaled. You have outdone us all on the book problem, and I am glad of it.

Chas. Dadant & Son write:—The book is at hand, and though we do not agree with all it contains, we must say that it is as neat and tastefully gotten up as any thing we ever saw.

The *Bee-Keepers' Magazine* says:—"The Production of Comb Honey" is the title of a unique little work of 45 pages, by the pen of W. Z. Hutchinson. Mr. Hutchinson struck a happy idea when he designed the cover of his work.

Prof. Cook offered congratulations again and again, saying:—It is decidedly the most unique little thing I have seen in a long time. Why, that cover alone ought to sell it, to say nothing of the good things inside.

The above are fair specimens of scores of similar testimonials that I have received, *unsolicited*.

Reader, if you wish to see a little typographical "gem," send 25 cents for "The Production of Comb Honey."—Stamps taken; either U. S. or Canadian.

WANTED.—To exchange new Centennial incubator, for Barnes' saw. Box 1, Mulberry, Pa.

POTATO BOXES

(TERRY'S).

These are made of basswood, bound with galvanized iron. The galvanized iron gives strength, and the basswood strength and lightness. These hold exactly a bushel when level full, and may be piled one on top of another. Although they are made especially for potatoes, they can be used for fruit, vegetables, picking up stones on the farm, and a thousand other purposes. When piled one above the other, they protect the contents from the sun and rain; and from their shape a great many more bushels can be set into a wagon than where baskets are used. They are also much more substantial than baskets.

Price 25 c each; 10, \$2.25; 100, \$20.00. In the flat, including nails and galvanized iron, \$1.75 for 10; 100, \$16.50; 1000, \$150.

Cash for Beeswax!

Will pay 20c per lb. cash, or 23c in trade for any quantity of good, fair, average beeswax, delivered at our R. R. station. The same will be sold to those who wish to purchase, at 25c per lb., or 28c for best selected wax.

Unless you put your name on the box, and notify us by mail of amount sent, I can not hold myself responsible for mistakes. It will not pay as a general thing to send wax by express.

A. I. ROOT, Medina, Ohio.

COMMON SENSE Automatic Door - Check.

SOMETHING THAT EVERY GOOD HOUSEWIFE
HAS BEEN LOOKING FOR.

Who has not felt the need of some simple and effective device for holding a door at any desired position? Many times you want to let in a very small amount of air, and it is difficult to fasten the door just where you want it. Many people use a couple of bricks, but these are unhandy, and ungainly looking things.

The accompanying cut shows the nicest thing for the purpose we have ever found. It is very simple, and yet very effective. It is attached to the corner of the door with four screws. You place your door just where you want it and press your toe on the upper end, pressing it hard against the floor. In the meantime the small dog catches it and holds it there and your door is securely fastened. When you want to release it to shut or open the door, simply touch your toe to the dog, and the spring inside presses the center bar up out of the way. The lower end has a rubber cap inserted so that it may be used on a carpeted floor, or even on a nice hard-finished floor, without injury.

If you try one you will want one for every door in your house. The price is only 35 cts.; by mail, postpaid, 45 cts.

A. I. ROOT, Medina, Ohio.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough to these queens to pay for buying them up and keeping them in stock; and yet it is oftentimes quite an accommodation to those who can not afford higher-priced ones.

I am requeening my apiary of Italian bees, and will sell queens at 50 cents apiece. Satisfaction and safe arrival guaranteed. HARRY G. CAMP,
Winona, Col. Co., O.

I have one black queen for sale at 25 cents. Mismatched Italians, or hybrids, 50 cts.
R. H. BAILEY, Ausable Forks, N. Y.

Black and hybrid queens for sale; black, 15 cts.; hybrid, 25 cts.; mismatched, 40 cts.
W. G. HAYEN, Pleasant Mound, Bond Co., Ill.

For Sale.—3 mismatched Italian queens, at 50 cents each. Safe arrival guaranteed.
CHAS. MCCLAVE, New London, O.

During the latter part of July I will sell 40 hybrid queens at 25 cts., or five for a dollar. All of '86 and '87 rearing. Stamps taken. Satisfaction guaranteed.
L. H. ROBEY,
Worthington, Marion Co., W. Va.

I have some fine mismatched Italian queens for sale at 40 and 50 cts. each
J. W. SHELLEY,
Nicholasville, Ky.

KIND WORDS FROM OUR CUSTOMERS

The T super was received July 2, and in good condition. I never saw much nicer lumber. The tins are "dandies." Accept thanks. W. A. LAWRENCE.
Wayland, N. Y., July 4, 1887.

THE DOUBLE-WHEEL HOES.

The Planet Jr. double-wheel hoe, cultivator, and plow came to hand in good order one week from the day it was ordered. It gives perfect satisfaction. My three boys delight working with it.
Pittsburgh, Pa., June 21, 1887. T. C. DAVIS.

THE WHEELBARROW.

The two wheelbarrows I ordered of you came all right, in just 7 days from the time I sent the order, in splendid condition. We are well pleased with them. I don't know how such a neat little barrow can be made for \$4.00. I would not take \$5.00 for mine. Bees are working on basswood very lively.
Morristown, Ind., June 20, 1887. M. TALBERT.

A HOUSEHOLD NECESSITY.

GLEANINGS has come to be a household necessity with us. Mrs. L. says we can not do without it, and my little girl is much interested in the young folks' department. I got a good deal of help from all departments in the magazine, and I will say, with Mr. Pond, that you will never know here how much good you are doing.
Norridgewock, Me., May 12, 1887. W. B. LONGLEY.

IN DEFENSE OF OUR GOODS; THAT WAX-EXTRACTOR.

I was reading in GLEANINGS, page 387, 1887, a little complaint against you and your goods from P. Schons. I don't see how he got such a bad wax-extractor as he said he did, for I purchased one of you in 1886. It worked like a charm. In place of losing 5 lbs. of wax, as Mr. S. said he did, I am fully satisfied that I gained 10 lbs. in using the extractor in place of extracting the old way. And he complains of his goods coming too late. In regard to that, I purchased goods of you in 1886. They came four days sooner than I expected them to come, and I told you to send them by express, which you did. I did not ask you to mark them as corn, as Mr. S. would like you to mark his goods. I have always found you square in your dealings. Any one who is making complaint of you is doing more than I can do.
JOHN H. PENCE.

Terre Haute, Ohio, June 13, 1887.

HONEY COLUMN.

CITY MARKETS.

ST. LOUIS.—*Honey*.—We quote choice comb 8@10 cts.; latter is for choice white clover in good condition. Strained in bbls., 3½@4 cts. Extra fancy, of bright color and in No. 1 packages, ½ cent advance on above. Extracted in bbls., 4¼@4½ cts.; in cans, 5 cts. Market dull and receipts increasing.

Beeswax steady at 21 cts. for prime.

July 11. D. G. TUTT & Co.,
206 N. Commercial St., St. Louis, Mo.

CHICAGO.—*Honey*.—The crop of 1886 has been exhausted, so far as this market is concerned, in comb honey. A little of the new crop has come forward and sold at 15@16c in one-pound sections. Quite a quantity could be sold now in a small way. Extracted, 5@7c. *Beeswax*, 22c. R. A. BURNETT,
July 9. 161 So. Water St., Chicago, Ill.

CINCINNATI.—*Honey*.—Demand is fair for the season for nice comb honey and extracted in square glass jars and tin buckets for table use. There is also a good demand from manufacturers for dark grades of extracted honey. Prices for comb honey are nominal, no new being in our market as yet. Extracted brings 3@7c per lb. on arrival. *Beeswax* is in good demand and brings 20@22c per lb. on arrival for good to choice yellow.

July 9. CHAS. F. MUTH & SON,
Cincinnati, O.

COLUMBUS.—*Honey*.—The honey market in this section of Ohio will no doubt be very good for shippers, as all this section of country, so far as I can learn from the best sources, will be very scarce, and no doubt a large quantity can be sold here. I shall not have anywhere near enough to supply my demands, and I should like to hear from all those having quantities. Prices rule about as follows: Extracted, 8@10c; comb, pure white clover, 15@18c. No new honey in as yet.

July 9. EARL CLICKINGER,
117 S. 4th St., Columbus, O.

DETROIT.—*Honey*.—New honey in small lots, nicely put up, brings 12½ cts., and likely to improve in price, as the crop in Michigan is short. *Beeswax*, 23c.
July 12. M. H. HUNT, Bell Branch, Mich.

BOSTON.—*Honey*.—We have no change in prices to report. Sales very light. Fancy white extracted in good demand, with a very limited supply.

July 11. BLAKE & RIPLEY,
57 Chatham St., Boston, Mass.

KANSAS CITY.—*Honey*.—There is no new honey in our market yet. Can't give quotations. *Beeswax*, 18@20c.

July 11. CLEMONS, CLOON & Co.,
Kansas City, Mo.

PHILADELPHIA.—*Honey*.—No movement, nominal. *Beeswax*, quiet; white, 26@28; choice yellow, 22@24; common, 18@20; dark, 16@18.

July 12. PANCOAST & GRIFFITHS,
Philadelphia, Pa.

ST. LOUIS.—*Honey*.—Think the old stock of honey is pretty well closed out; some few lots still on the market. White clover, 1-lb. sections, as to quality, 8@10c; extracted, clover, bbls., 4@5c; cans, 5@5½c. Southern honey, some new coming in; extracted, in bbls., 3½c; sold 5000 lbs. to-day. *Beeswax*, 21c; original selected, 23½c.

July 11. W. B. WESTCOTT & Co.,
108 and 110 Market St., St. Louis, Mo.

A HOUSE FOR THE APIARY.

PROF. COOK GIVES US HIS IDEAS ON THE SUBJECT.

MR. ROOT:—I have been giving much thought of late to the plan for an ideal house for the apiary. You will remember we talked of it while you were here. I have also conferred with such authorities as Messrs. Hutchinson, Doolittle, Dr. Miller, Heddon, etc. It seems to me that this is a question of exceeding importance, and I wish to submit my drawings and reasons for this plan for criticisms, that we may secure the very best. The house is three stories—a cellar 7 ft. high; first floor 8 ft., and chamber 6 ft. at the lowest part. The cellar is for wintering bees; the rooms above are for honey, extracting, and shop; the chamber is for storage. The cellar has two rooms. One, for bees in winter, is 18 × 24 ft. This is entirely under ground, with a good stone wall, grouted below and plastered above, with a double floor grouted between—to secure against mice and cold alike, and with the partition wall double, with double doors. At the center of the partition wall a small chimney runs from the bottom of the cellar up to and through the roof. Just within the wall of this room is a small gutter which extends nearly around the room, as seen in the drawing, from one end of a cistern to the underground sub-earth ventilation-pipe which runs 200 feet or more under ground. Thus this pipe of four-inch glazed tile serves for sub-earth ventilation, overflow-pipe for a cellar cistern, and it can be made to empty the cistern and cool the bee-cellar at any time, the water passing through the small gutter.

In the other room of the cellar, which is 8 × 24 ft., there is a cistern 8 × 14 ft., and 5 ft. high. As will be seen, this extends 2 ft. into the bee-cellar, yet the

partition is tight, except a small hole just at the bottom, so we may say we have two cisterns—one a small one in the bee-cellar, the other a large one in the other cellar, though they are connected at the bottom. The other room, which is a sort of vestibule for the bee-cellar, has two windows—one (1 × 2) by 2 ft., and stairs to the room above, which are covered by double trap-doors. This room is entirely under ground, though the outer double door, which is 4 ft. wide, is, because of a natural slope of the ground, on a level with the outside, or else is inclined so we can easily run a wheelbarrow into the cellar. The windows may receive light by a half-circular excavation, or, if desired, may be above the earth at this south-east corner of the house.

Here, then, we have an arrangement by which we can control the temperature perfectly, from October to May; and from an experience extending now over eight years, I am sure that, with enough good food, bees are entirely safe in such a cellar. By aid of the cistern there is no occasion to use ice to reduce the temperature in spring; and we can, by aid of sub-earth ventilation and cistern water, keep the temperature just to our liking all through the winter, with almost no trouble and at no expense. This is no theory: it is demonstrated fact. As the bees can be wheeled into the cellar, their removal to or from the cellar is a very light task.

On the ground floor, which is on a level with the earth outside, there are three rooms. One on the south-west, 12 × 15 ft., is for extracting and extracted honey. It has a hard-wood floor, wide outer door, and only one thickness of wall, so that in summer it is kept very warm, and so enables us to ripen honey without leaving it in the hive till it is all capped. This is also a demonstrated fact. The joists above are just so wide that they serve as

frame - supports. The windows are poised with weights, and these and the door have an outer gauze hinged frame. In case of the windows, this extends three inches above the outer wall, leaving a half-inch space, so that bees can easily pass out, while they do not pass in.

A second room on the south-east is also the same size, but is double walled, lathed and plastered. It contains a stove, but has no outer door. It is for comb honey, for an office, and has trap-doors to cellar stairs. I find that some are not in favor of this room, but I think it very desirable.

Fig. 1. Diagram of cellar.

REFERENCES AND REMARKS TO FIG. 1.

D, 4-ft. double doors.

I, gutter.

J, stone wall 4 1/2 feet, or all the way up.

L, double wall lined with paper.

M, passageway from cellar, with stone abutments on each side, and level with outside, so a wheelbarrow can be run in and out.

O, drain of 6-inch tile—Dr. Miller says 10-inch—following the dotted lines 200 feet, and all the way below frost or variable-temperature mark.

W, cellar windows, 1 x 2 1/2 ft., double; outer glass, and inner wood. Both are hinged above so as to open in easily.

Fig. 2. Diagram of first floor.

REFERENCES AND REMARKS TO FIG. 2.

D, doors, the double one at the bottom having a sill so low a wheelbarrow can be run over it, outside door being of gauze.

W, windows, all of which have wire gauze screens outside, and hinged to swing out. Screens on four south windows to extend 4 inches above upper jamb, with 1/2 inch space.

Posts 14 ft. Studding, to chamber, alternate 12 and 18 inches apart (5). Side-studding 12 feet long and 1 foot apart.

Floor, double, one foot apart, and with grouting.

Cellar and house mouse proof.

The entire north side of the building is for a shop. This is 12 x 30 ft. It has a pump from the cistern below, and stairs to the chamber above. It has an outside door, four windows, and a door into each of the other rooms. There will also be a stove in this room. In winter, then, when we have a fire in either room, the chimney will be heated, and the air drawn from the bee-cellar. The wind, too, passing over the chimney, will suck the air from the cellar. In both cases the air is supplied through the long sub-earth pipe, and so is tempered by the temperature of the earth, and is kept sweet and pure. This is both theory and demonstrated fact. This room is large enough so that a small engine and some machinery can be introduced if desired. I find that this house, large enough for a large apiary, can be built for \$500; and for safety and convenience I believe it fills the bill. I can not agree with Mr. Heddon, that we had better have double-walled houses above ground. I think the cellar far better and more convenient. I shall be very glad to have this plan criticised in the next number of GLEANINGS, for, as stated before, this is a matter of great importance to all bee-keepers in the Northern States and in Canada.

A. J. COOK.

Agricultural College, Mich., June, 1887.

Since the above was in type, friend Cook sends us the following note:

Some of our best apiarists say the walls above should be double, with one-foot space all around filled with sawdust; and some object to dividing the south half of the building into two parts. I still think the double-walled space a useless expense, but will so make the building that it can be thus changed at any time. I also wish the two separate south rooms.

A. J. COOK.

You have made exactly what we want, friend Cook, and I heartily indorse your remarks in regard to criticisms. Let us have this thing fully discussed. To start the matter going, I would inquire if you expect the one who operates the extractor, to work in a room hot enough to evaporate the liquid honey properly. Extracting is often done in the very warmest weather; and for my part I should want lots of doors and windows, to be covered with wire cloth, whenever the bees might be disposed to be meddlesome. And why do you have a separate space for the comb and liquid honey during the ripening process? Or have I misunderstood your description? I presume the chamber is to be also used for ripening honey. If so, would it have to be finished off on the plan suggested by friend Doolittle, so that it will ripen the comb honey enough to prevent dripping from unsealed cells? There is a vast field open on this subject for questions and answers, but I will not occupy more space at present.

WHAT HAS THE HARVEST BEEN?

AND SHALL WE BE IN A HURRY ABOUT SELLING WHAT WE HAVE?

It has been pretty slim here—the poorest since I have been in the business. In a letter just received from Mr. Heddon, he says: “Clover, cue-fourth crop. Basswood blossomed full, but no better crop than clover. It went right by like a cyclone—all over before we knew it was

drawing to a close." This expresses the situation exactly. Well, what are we going to do about it? We can keep our dishes right side up, and I presume most of us have lost nothing from lack of care in this direction, but we can't make honey-showers. Those of us who are fortunate enough to have any surplus will probably find ready sale for our honey at a good figure. Prices will probably not go so high that our income will be what it would have been had the harvest been abundant; still, this is not impossible. Farmers sometimes make the most money during the years when crops are light. Twenty-five or even twenty cents per pound for comb honey would be a big boost for those of us who have a few hundred pounds to sell. That these figures may be reached, does not seem at all improbable. Already honey is being quoted at 16 to 18 cts., while nearly every market is reported as bare of honey. Honey-dealers are becoming really interested in the situation. Only a few days ago I received a letter from Thurber, Whyland & Co., making inquiries in regard to the honey-crop, and asking, "What is the outlook?" Those who have honey to sell should not be in a hurry to market. Certainly nothing can be lost by waiting until November or December.

And now a word about the bees. Many of them will probably be short of stores, and, unless fed, will die of starvation the coming winter. Many bee-keepers will "lose their heads," become disgusted and discouraged with the bee-business, and the bees will be neglected. Honey will bring a big price, and by next spring their courage will return, and those who have bees to sell will have no difficulty in getting good prices. So, to those who will attend strictly to business the short crop of this year may be a blessing in disguise. See that the bees are well cared for; that they go into winter quarters in first-class condition. This will probably be one of the years when it will pay to winter the bees on sugar, as the difference in price between honey and sugar will be greater than it has been in several years. Keep a stiff upper lip, and, if you must retreat, do so in good order. W. Z. HUTCHINSON.

Rogersville, Mich., July 11, 1887.

SOME SUGGESTIONS AND CAUTIONS.

FEEDING A COLONY FROM WHICH A SWARM HAS ISSUED.

A CORRESPONDENT writes us: "I wish you would tell us in GLEANINGS some quick, reliable method of determining from which colony a swarm has issued, said swarm having come out in the absence of the apiarist, and is found by him on his return hanging on a limb." Well, here is the way I do. Finding such a swarm, and not knowing where it came from, I take a box which will hold about a quart, and get about a tea-cupful of the bees in it, which are kept confined while the rest of the swarm is being hived. If one side of the box is of glass it can be positively known if you get the queen with your few bees, yet she is not very apt to be where you will get her. Having the swarm hived, they are to be carried to where they are to stand, when I uncover the box, and with a kind of whirling motion I toss the bees out of the box into the air. After circling about a moment or so they will return to the hive the

swarm came from, commencing to fan their wings in front of the entrance, thus quickly and certainly telling you where they came from. After throwing them in the air I wait a moment or two, when I rapidly pass through the bee-yard till I see them fanning at a hive. In this way it is easy to know all about it, even in a large apiary of 200 or 300 colonies.

YIELD FROM WHITE CLOVER.

Another writes: "I have seen it stated as a fact that there is no such a thing as overstocking a locality with bees, that a single acre of white clover will furnish, in a good season, at least 100 pounds of surplus each, to 25 or 30 colonies. Is this a fact?" Let us figure a little. That would be 2500 lbs. at the lowest estimate, in surplus honey, for an acre of white clover in a single season, to say nothing about what the bees consume. Then a square mile would give 1,600,000 lbs. of surplus; and if, as I claim, the flight of bees reaches four to five miles from the apiary in every direction, we should have the enormous amount of—well, we have lost our breath trying to comprehend that product, as it exceeds the production of the world. Talk about legislation for bee-keepers! All Dr. Miller has to do is to fence off a few acres of his farm, and he is a rich man; yet the above estimate was made, if my memory serves me right, by one of our most noted writers on the honey-bee. I never saw an acre of clover which I thought yielded 50 lbs. of honey; for had it done so, when more bees were added to my locality the average yield would not have decreased as it has done. When it comes to basswood, with a good yield, I do not know that we have ever been overstocked; for at such times a bee could load up on a single sprig of blossoms, and, when he returned, could get another load again; yet it is not often that even basswood yields like this. At such times it is no great stretch of the imagination to believe a large tree in the open lot would produce 50 pounds, or as much as an acre of clover; but when we really come down to the truth of the matter, what do we know about it? Well, even admitting we know very little about it, I think we know only enough to credit the quoted statement as fallacious.

EXTRACTING FROM BROOD-COMBS.

Still another writes: "Shall I extract the honey from the brood-combs when working the apiary for comb honey? Some of my colonies have several frames nearly filled with honey, and are crowding the queens, not going into the sections at all." I am led to mistrust that the colonies spoken of above have not been rightly managed, or they would not be in this condition. I find that, when bees are allowed to begin the storing of any great amount of honey in the brood-nest, they will continue so to do to a greater or less extent the entire season; that is, a colony that is allowed to cramp the queen once is very likely to continue it throughout the whole season. Very much depends on the control which is had over the brood-nest during the preparation of the colony for the season's work—such control as can be had only by an apiarist who is thoroughly familiar with all the habits of the bee, and who, by the use of division-boards, reduces the size of the brood-nest to the necessities of the colony, or enlarges it as is required to meet the demands of the queen, thus managing the brood-chamber so that, at the commence-

ment of the honey-flow, it will be entirely filled with brood, leaving but little if any space in which the bees may deposit honey, but forcing or compelling them to go into the sections for the necessary room to store it. This, I think, is the only way that comb honey can be secured successfully. A few extra combs, and the use of the extractor on them, would spoil the whole thing. Some prefer a half-depth brood-chamber instead of the division-boards to accomplish the above object; but whatever plan is used, the principle is the same. I think it is safe to say that few if any of the bee-keepers of the present time use the extractor on the combs of the brood-chamber while working for comb honey. G. M. DOOLITTLE.

Borodino, N. Y., June 1, 1887.

In justice to friend Doolittle, it is proper to state that the foregoing article should have appeared in GLEANINGS for June 15; but by an oversight it was omitted. We regret this, inasmuch as the subject treats of swarming. No doubt the article will be found seasonable even yet, in some localities. —Friend D., your method of telling where the swarm came from is quite ingenious, and I know it will work, for I have tried it many times since you or somebody else gave it several years ago. While it is true, that we are comparatively unable to tell about how much honey an acre of clover or even basswood will furnish, I am inclined to think it has been put too high. See my figures in regard to the spider plant, in the A B C book. If an acre of buckwheat furnishes 50 lbs. of honey during the whole time it is in bloom, I am inclined to think it is an extra good crop, and I do not believe white clover often does better. I know a large basswood-tree, in an open lot, will yield a great amount of honey; but it seems to me quite doubtful if any single tree ever produces as much as 50 lbs. in one season. Honey from all these sources, when first gathered, is comparatively watery, and must be evaporated a great deal before it becomes honey such as we would put on the market. I think you are right about extracting from brood-combs. Although we have sold many extractors to bee-keepers who were working for comb honey exclusively, I have always been sorry to sell them one when they gave as a reason for wanting it, that there was too much honey in the brood-combs.

OUR P. BENSON LETTER.

GRAND ENTERPRISE!!! AMERICAN BEE-KEEPERS' STORE.

BEE-KEEPERS arise in yure mite! Trooth is mitey and will prevale. The grate coz of the depreshen in the hunny market is the lo price of hunny. This is projuced by the commition men. So mutch bizness is poot into thare hands that sum of them is makin munny at it. And the way thay do with the hunny is a outrag. I will sightl instants. A man by the name of Mut from Jirmany set up in the commition bizness a sellin of hunny. Hunny was sent to him from every ¼. Now what did he do with that hunny? Why he sold it for all sorts of things. Hunny is a dellick-

asy and hed ot to be poot on the table of the ritch, but this retch, Mut, sold it to ritch and poor alike and tried to git every buddy to buy it. Think of that, poor peapel that cood hardly afford to by butter, a eatin nice hunny onto thair bread. But that wuzzent the werst. He sold hunny even for me-cannickie purposes. Sum of it he soled to bake with, & sum to print with, and some to maik hams with. Think of that! a taking good hunny to poot on greezy hams. He also sold sum in the jirman language.

I think I hev now shone quite clearly that the commition men is the trubble, and as I have the good of bee-keepers at hart I have thot out a plan whairby in whitc evry bee-keeper ken set his oan price on his hunny. The hunny shoold all go to 1 common scenter and then it can be controaled. Sum men goze around and sells thair hunny to the farmers. Enny man which does that lax common scents. If the farmers wants hunny, let them cum for it. Ol the bee-keepers will send thair hunny to 1 scentral point and I will be thair agent and re-seeve it in a fine, large bildding maid for that purpose. It will be called the American Bee-Keepers'

P. BENSON'S HONEY-STORE.

Store. Evry man will send me his hunny and set his oan price to it, and I will sell it at a nominal commition of ½ of 1 per scent. For instants, if he wants 20 scents for his hunny, for evry scent he wants to git, he will send me ½ of 1 scent, so he will send me 10 scents, and when I sell the hunny I will send him 20 scents. The commition must be sent in advance as I doant do a credit bizness, for I doant want to encurridge enny buddy going in det. Det hez bin the rooin of menny a man. You see thair will be no trubble in this wa for them that thinks hunny ot to bring 10 (ten) scents ken poot that price on thair hunny and them that wants it ken poot (30) thirty scents onto thair hunny. In order to help bare expenses I will charge 1 scent a pound each month for stowridge, and if the stowridge gits moar than the price of the hunny, I will take the hunny for part pay and thay ken send a post office order for the balence.

Enny 1 whitc rites letters of inquiry will send his reel name not nesserly for publickashen but as a garntea of good faith. P. BENSON, A. B. S. Whitc it stands for Agent Bee-Keepers' Store.

THE USE OF WIRE IN FOUNDATION.

THE SLATTED WOOD-ZINC HONEY-BOARD.

FROM the *Canadian Bee Journal* of June 29 we take the following article, with the answer by the editor. There is so much of interest and so much of practical value in it that we feel sure our readers in the States can not afford to lose the benefits of the suggestions offered by friend Jones:

I have tried my extractor, and it does the work all right; but I can not get the foundation comb to work. It goes all out of shape as soon as the bees begin to work it out. Do you put it in full size of frames, or do you allow for stretching? I tried three different hives filled with foundation, but had to take the frames out about the second or third day, and take the greater part of the foundation out. I fastened it only at the top, and allowed the bottom to hang loose.

HONEY-BOARDS.

Do you use the metal honey-board on the two-story hive to prevent queens getting into the upper half? Can it not be taken off after the lower half contains young brood? It is quite a hindrance to the bees getting up and down. Please let me have a little information on the above points.

FOUNDATION IN SECTIONS.

I have also some trouble with foundation in the section boxes becoming displaced. Should it be fastened on more than one side or not?

Howick, P. Q., June 21, 1887.

WM. GEBBIE.

The following is the answer to the above, by the editor, D. A. Jones:

Unless foundation is made heavier than is profitable it will usually sag, and our customers prefer it made the thickness that we send it out. We now use wired frames when we put in full sheets, and we think that if you will use wire once you will be satisfied with the result. We have not used it very much; but where the wire is used, the foundation may be much lighter—say one-third. This reduces the expense of foundation per hive one-third, which is quite an item in a large apiary. Deduct from that the cost of the wire, which is a mere trifle, and the wiring will yet leave you twenty-five per cent advantage. Thin foundation may be used in frames, however, as we frequently use it in full sheets by placing one frame with foundation between two combs, crowding the combs up close enough so the bees do not cluster on the foundation but hang their whole weight there while drawing it out and attaching it to the frame and leaving only about half an inch space between combs, and foundation on either side. This allows the bees to rest much of their weight on the combs until the foundation is partially drawn out. Foundation placed in strong colonies for, say, one day in the above way, will be drawn out and attached to the frame sufficiently to allow large swarms to be hived without breaking down, even in hot weather. Before we used wire we had some strong colonies draw out enough foundation in a week to have three or four swarms; and as soon as one lot of foundation was drawn out it could be removed and put in empty hives for future use, and fresh frames filled with foundation could be put in their places.

We use the perforated metal honey-board, or, rather, the wood-and-metal honey-board, which is a great improvement on the metal one, inasmuch as the wood holds the metal from sagging, and always keeps the distance of the bee-space the same. It prevents the storing of pollen in sections or combs above, and also prevents drones from passing up, moving over the sections and soiling them; but the most important point is to prevent the queen from ascending to the second story and filling it with brood. We find that it is unnecessary and a great waste of surplus to raise a large quantity of brood and bees that will hatch just as the honey season is over; they become consumers rather than producers in the large amount of time and stores consumed in feeding larvae. Then after they are hatched it is usually about ten days before they commence gathering honey so that you can see when you know the time your honey-flow ceases about the right time to crowd the queen up on fewer combs.

It should be done from thirty to thirty-five days before the end of the honey-flow. These bees hatched just at the end of the honey-season, and are rather too old to go into winter quarters, but many of them die before they are set in, or soon after. Those raised later on, that have not worn themselves out in search of stores, are the ones most desirable for wintering; then when they are set out in the spring they are more vigorous, and do not die off so early, or "spring dwindle," like those that are old when set into winter quarters. This is a very important matter, and should receive attention; and if carefully managed it will save at least twenty-five pounds of honey per colony.

These perforated wood-and-metal queen-excluders do not prevent the bees from storing honey in the upper story, or sections, and should be left on until the upper stories and sections are removed. There is ten times as much room for the bees to enter the upper story as at the entrance to the hive. This same perforated metal, made into drone-traps, does not prevent the bees from passing in and out; therefore, when they have ten times as much room as an ordinary entrance, besides many of the bees do not require to enter the second story and remain below, we fail to see how it can in any way lessen the honey crop. Careful observers are using it more extensively every year. We sell thousands of feet of it, and the sale is increasing.

If your sections are warm and the wax cool, and you press it on firmly, it will not come off. If you drop a piece of hot wax on a cold surface it cools so quickly that it will slip off by pushing it with your finger-nail, or if you drop cold wax on a hot surface it will incorporate in the wood and can not be removed, therefore you will readily see the necessity of having your sections warm, foundation cold, and pressing very firmly.

We have never had so many good reports about our foundation before. This is the first intimation of any difficulty this season.

MILLER'S PLAN OF REMOVING SECTIONS FROM WIDE FRAMES.

OUR FRIEND "CHARLIE" TELLS HOW TO DO IT.

SINCE the T super, the Heddon crate, and other similar surplus receptacles have begun to assert their superior merits, the old eight-section wide frame has been superseded in many cases; but there is a very large number of our readers who, though recognizing some of the superior advantages of the more recent improvements, yet, from lack of means, and for fear they may not like them any better, will still continue to use for some time their double-tier wide frames. One very great objection to these latter is the amount of labor entailed in securing a crop of honey by their use. The chief difficulty seems to be in removing the sections, after they are filled, easily, quickly, and without damage to the sections. Dr. Miller invented a plan which we think is equal if not superior to any other method we have seen. On page 35 of "A Year Among the Bees," in discussing the different methods of removing the sections from wide frames, he says: "I adopted a plan which allowed them to be taken out very rapidly. This was Charlie's specialty, and he became so expert at it that I think it would be difficult for any one to take out sections faster, no matter what kind of a surplus case might be used. At his best he can take out 960 sections per hour. Moreover I have some doubt if there is any surplus case used from which the sections are more easily and rapidly taken than from these same wide frames."

As there are many of our readers, doubt-

less, who would like to have further particulars in regard to this plan of removing sections, we requested the two Millers, with the assistance of the engravings below, to describe the plan in full—the senior Miller to tell how to construct the machine itself, and the junior Miller to particularize just how he was able to remove 960 sections per hour at his best. The doctor describes the machine as follows:

FIG. 2. SECTIONS AFTER REMOVED FROM WIDE FRAME.

The cuts show pretty well just what the machine is, only the engraving makes the two back strips look as if they were part of the ends instead of separate pieces nailed on. The ends (B, Fig. 2) are 11x4, with a notch cut out of the upper front corner, two inches square. The bottom is 20 by 4 3/4 inches, and is nailed upon the end-pieces, projecting back 3/4 in., as 3/8-inch stuff is used in making the machine. At the top of the end-piece, B, is nailed on a back strip 2 x 20 in., and at the bottom a strip 3/8 in. sq. by 20 in. long. From one of these pieces to the other is stretched tightly a piece of strong cotton cloth, occupying the whole width of the machine, and this cloth serves as a cushion for the sections to fall against when pushed out. If a frame is now hung in the machine (as at Fig. 1), and we attempt to push out the sections, the upper part will be held firmly in place, but the lower part of the frame will swing back against the cloth. To prevent this, stops must be nailed on the inside of the end-pieces for the lower end of the wide frame to rest against; but these stops must not be thick enough to interfere with the sections as they are pushed out. Wedge-shaped pieces should be in front of these stops, so that the frame may enter easily, but when pushed back to place will have very little play sideways. Perhaps it is best to have the stop and the wedge-shaped piece all in one piece. If we now attempt to push out sections they will, as soon as free from the frame, drop from the frame upon the bottom of the machine, a distance a little more than the thickness of the bottom-bar of the wide frame. It is better that they should not have this drop, so a strip is nailed upon the bottom about two inches in width, and thick enough so the sections

will have the least possible drop as they are pushed out of the frame.

The machine is now complete, except that a piece of board should be nailed under the front part of the bottom, so that, when the machine is fastened upon the table (by screws, nails, or clamps) the top shall tip back two or three inches. It must be made very firm, and it is a good plan to have the table pushed back against the wall, and a solid box or boxes fill up the space between the machine and the wall.

The push-stick (C, Fig. 2) appears rather heavy in the engraving. It should be made of some tough hard wood, about 9 inches long and 3/4 of an inch square. At one end, cut a shoulder clear around, 1/4 of an inch deep, leaving a tenon 1/4 inch square and 1/4 inch long at the end of the stick. The stick tapers to the other end, so that, for about 2 inches, it shall not be more than 1/4 of an inch thick, the extreme end being a little less than that.

Marengo, Ill.

C. C. MILLER.

The following is from the pen of C. C. Miller, Jr., describing how to manipulate:

Place a pile of supers so that, as you stand in front of the machine, you can reach the frames easily. Besides your stick, you will need a large jack-knife and a common case-knife. Hang a frame in the machine and you are ready to begin operations. Take the case knife (I use a stiff round-pointed one) and run it down between the sections and separator to loosen the tin, noticing if the comb is built on the tin anywhere. If it is, be sure to cut it loose, to save its tearing and making a bad leak.

Next run the jack-knife between the sections and

FIG. 1. THE METHOD OF PUSHING THE SECTIONS FROM THE WIDE FRAMES, WITH THE PUSH-STICK.

bottom-bar, taking pains to get exactly in the middle of the frame and under the corners of the two middle sections. The advantage of the jack-knife is in its being wedge-shaped, and so loosening the bottom-bar more completely than the case-knife. Care should be taken never to pry under the middle of the common section, as they will spring just a little, making a crack in the comb, allowing the honey to leak, although so slowly that it will probably not be noticed till after the section is crated, making a dauby package to put on the market.

Loosen the top-bar in the same manner. Now take the end of the push-stick with the shoulder,

and start each corner. I usually go around in this order:

2	1
3	4

This keeps the tops of the sections a trifle ahead of the bottom. Possibly it is habit or prejudice, but it doesn't seem as if the sections bind quite so much so, as they do if the bottom is ahead.

As soon as you have started two or three pretty solid corners you will realize the advantage of the shoulder on the push-stick to keep it from slipping and gouging the section. Change ends with your stick, and push carefully around in the same order as before, except that you push in the middle of the frame just under the top-bar, above and in the middle just over the bottom-bar below. Keep going around till you get the sections clear from the frame. I usually go around about three or four times. If you push one corner too far ahead it racks the section, causing a leak.

Take the empty frame off the machine, and hang it back in one side of your super. In taking the sections off the machine I take two in each hand, catching the corners of two between my thumb and forefinger; and in putting them down I take care to pile them nicely. You need have no fear of making too large a pile on account of mashing down the bottom sections, as I have seen between twenty-five and thirty thousand in a pile, with nothing at all between the tiers; the only thing about it different from the ordinary way was, that one layer faced one way, and the next layer the other way, and so on up, instead of having them all run one way and overlap one another, as is generally done.

C. C. MILLER, JR.

Upon reading C. C. Miller, Jr.'s part of the programme, we are convinced that he is a veritable "son of his father." I think it is not too much to say of C. C. Miller, Sr., that he has a very simple and clear way of expressing his ideas; and if we can judge any thing from the article received from the son, we should say that C. C. Miller, Jr., will follow closely in his father's footsteps. We think our readers will find the two articles will throw considerable light on just how to remove sections from wide frames.

IS DOOLITTLE'S THEORY OF SWARMING CORRECT?

QUEENS REMAINING IN THEIR CELLS, AND BEING FED.

ON page 434, June 1, Mr. Doolittle gives us some interesting reading about swarming, etc. His article is excellent. Enough is said in a nutshell to convince any intelligent reader of its truthfulness and solid facts. June 15, page 462, we see Mr. Dewey disagrees a little. He admits Doolittle as good authority, but the man to contradict him must be well posted. Of course, it takes an old veteran of thirty years' service to command the floor and make Doolittle take his seat among his junior brethren. Several queens must be heard piping, and be hatched and liberated in the hive before swarming takes place. I will here admit, that Mr. Dewey is right in what he has seen and heard, but is wrong in disputing Doolittle; for Doolittle is also correct in what he has seen and

written about in his article. Both these facts, and many others, occur within the bee-hive and with bees. Only last year I was pleased to see, where only one queen hatched in a hive, three were piping. I searched diligently (for I wanted to capture them) for the other two, and finally discovered them in their cells, poking out their tongues through a small hole, and being fed by the bees, but also guarded, which confinement caused them to pipe. I smoked the bees off the comb and cut out the queen-cells; when they immediately cut themselves out of their little prisons. The piping of the queen in this hive ceased at once while I was working with the bees.

I had a queen several years ago that kept up piping for about a week while being caged. I can remember another that acted strangely. A cell was introduced into a populous colony, with cells of their own. In a few days she hatched and was heard piping, when my father and I agreed to stop swarming by tearing out all the cells. No use. She kept up her music a few days longer, when out with a swarm she went, leaving the parent stock without queen, cell, or eggs. I mention these incidents to show how strangely bees will act sometimes. In laying down my pen I want to say to Mr. Dewey, continue experimenting and gathering knowledge as do Mr. Doolittle and many others.

Worden, Ill., June 23, 1887.

H. R. Dow.

VARIOUS MATTERS, FROM CHALON FOWLS.

WHAT TO DO WITH SURPLUS COMBS AFTER CONTRACTING.

I WILL explain to our readers, that, during my college days in Oberlin, friend Fowls would frequently give his familiar knock on the door while I was wrestling with an idiom in the dead languages, or tugging over a problem in mathematics. His visits were always welcome; and as he is an enthusiast on the subject of bees, and full of new experiments, I used to enjoy an hour or so chat with him. As I had not heard from my former visitor for some time, I wrote him a short time ago, asking him in regard to some of the things which he had under experiment—whether he still held the same opinion about some things that he did a few years ago while I was at Oberlin. The reader will readily divine the questions which I asked, from the replies which friend F. makes. His letter is as follows:

CARNIOLAN BEES.

Friend Ernest:—Yours was received some time ago, but I did not answer at once, as I wanted to take time enough to answer your questions. Bees wintered well, but came through short of stores. They have been on short rations all the spring. As a consequence, they have not bred up as well as usual. Bees will breed better, I find, with sealed honey along the top of the frame. I have one swarm of Carniolan bees with imported queen, and they did winter splendidly, and, having plenty of honey, bred up early and swarmed in May.

If I remember rightly, you once reported the Carniolan bees would not repel robbers very well. Ours do, equal to the best Italians. I have not tested their honey-gathering qualities much yet. They

are quiet on the comb, but I don't know about the crosses. I got a dollar Carniolan of Dr. Morrison, and her bees are the worst to run and cluster and drop off that I ever saw. If I have to use much smoke they will all boil out of the hive.

REVERSIBLE FRAMES.

You ask if I still like reversible frames as well as I did a year or so ago. I will answer, Yankee like, by asking if you have ever heard of any one who has given reversing a fair trial who did not like it better. To use them for only a swarm or two, I do not think a fair trial. I hived forty swarms on them two years ago, besides the few we had last year; and were it not for the fact that I can get the brood well up toward the top-bar by contraction I would use them, even if they cost ten cents extra instead of one. I have over 500 reversible frames, and wish every comb in my apiary were reversible. With new swarms I have reduced reversing to a practical system. I give new swarms five or six frames filled with foundation. If more frames are given them than the queen can occupy, the central ones will be solid with brood and the outside ones solid with honey, provided they are reversed at the right time. The proper time to reverse the first time is about the twelfth or thirteenth day after hiving. At that time the frame will have honey at the top, sealed brood in the center, and eggs and larvæ near the bottom. If any of the honey is capped in the top of the frame it should be lightly mashed down with the flat side of a knife. In nine or ten days more they should be reversed again, when the combs will be solid with brood; but they need to be reversed now so as to throw the larvæ and eggs above and the sealed brood below, where the bees are not inclined to store honey, and the queen will fill up the comb with eggs as fast as the bees hatch, so that in nine or ten days more the capped brood is all replaced by eggs and larvæ, when they are to be reversed again, and so on as long as honey is coming in fast enough to crowd the queen. The object is to reverse just often enough so as never to let any brood hatch in the upper part of the frames.

I will try to answer your other questions more briefly.

I use the old-style Heddon super; wide frames are out of date with me, and I don't use separators, but put full-sized starters in the sections and get combs straight enough when there is a good flow of honey. I think it might pay to use separators when honey is coming in slowly, but my supers will not admit of their use anyway.

The white clover began to "give down" the 18th. The bees are whitening the combs along the top-bars now, which tends to make the apiarist "feel good."

GILHOOLY'S VISIT.

I was just putting on the supers when along came neighbor Gilhooly.

"Hello, Fowls, you are shifting about, I see. Now, what are you trying to get that big swarm from that big chaff hive into that little Heddon hive for?"

"I am going to run them for comb honey, and my supers fit this hive."

"But you can't put ten frames in an eight-frame hive, and you have two frames in there now."

"No, they are dummies, made to fill the place of each outside frame. There, you see here are six

frames well filled with brood, and that just fills the hive."

"But here are four left covered with bees."

"Yes, and I will just shake them down here in front."

"But they'll hardly find room in there between those six frames of brood."

"Well, then they can go up in the super."

"I suppose you have that row of old sections in your super with comb in for bait; but why didn't you put them in the middle instead of the end? They would work at them more readily right over the center of the brood-nest."

"Yes, but they will occupy them promptly any way; and as they will be finished before the others, I would rather give the empty sections the most desirable place over that part of the frames containing the most brood."

"Why, look here, Fowls; here are eggs and larvæ in these four frames you have left in the chaff hive."

"Well, I'll put them in here. You see I have a lot of nuclei here, and their queens are not mated yet."

"What! are you raising queens for market too?"

"No; but I am starting nuclei as fast as I can get the cells, so as to have their queens laying by swarming time. I wish I could have a nucleus with a laying queen ready for every swarm that comes out."

"What now? some new hobby?"

"Why, that's the way I prevent after-swarms. I hive the new swarm on the old stand, so as to get all the flying bees, and set the old hive to one side till evening, when I carry it, with the comb of brood and young bees, and unite with one of these nuclei. In a few days the nuclei will be a powerful swarm for business."

"But, won't they swarm?"

"Not usually. The nucleus with a laying queen stops all that for at least the time being; but if they do, it will be a prime swarm any way."

"Why, Fowls, what does this mean? You must be crazy to saw new brood-frames in two."

"Oh, no! that's the way I make half-depth brood-frames."

"A'n't you going to have any bottom-bar?"

"No; they are only $4\frac{1}{4}$ inches deep."

"Well, what's your object in using them any way?"

"Oh! I just want to try Hutchinson's new departure, hiving new swarms in empty brood-chambers."

"Well, why don't you use your regular Simplicity frames?"

"I tried that last year, and it didn't work well. His directions are, to contract the brood-nest; and if you contract on the side, it makes it too narrow."

"But I don't see your hives to fit these little bottomless frames."

"Well, they are easily made. Just make a box half an inch smaller all around than the Simplicity or chaff hive; drop it in the bottom, put in the little frame, then the queen-excluding honey-board and super, and you are all right."

"Well, neighbor Fowls, it seems to me your new swarms treated in this way will be in mighty bad shape this fall for wintering."

"Perhaps so, if I were to leave them so; but I can easily shake them off the little combs, and let them have some old black combs for wintering."

"What will you do with the brood?"

"Let the bees care for it till it hatches in the upper story."

"Well, I must be going."

"Well, call again."

CHALON FOWLS.

Oberlin, Ohio, June 22, 1887.

Many thanks, friend Fowls. You seem to be as full of enthusiasm as you used to be, and I think the readers of GLEANINGS will all agree with us that your visit, through the medium of GLEANINGS, has been profitable to all.—In regard to reversing, I do not believe I can answer your Yankee question. For some reason or other we have not heard very much lately in regard to it. Knowing that you were once an advocate of the principle, I desired to know what you thought of it, even up to the present time, and am glad you like it. If I am correct, you are using Simplicity reversible wired corners. We are using them in our own apiaries, to the exclusion of all others. Your idea, whether original with yourself or not, of bringing the brood close to the surplus department above, by means of reversing, is good. Since receiving your manuscript we have tried a colony with the frames reversed as you direct. Up to the present time the plan seems to be working favorably, but we have hardly had time to see what the results would be. Mr. Gilhooly's visit reminds me somewhat of the visits I used to make you. I do not know that I propounded so many practical questions; but I am sure that all of us, as well as your friend Gilhooly, will understand your system of contracting, and what you do with the surplus combs after contraction. Your method of converting Simplicity or chaff hives into small Heddon hives, with half-depth frames, is quite feasible. Those who do not wish to go to any great expense in testing the Heddon and Hutchinson systems can do so in the way you suggest, at a very small outlay, and yet arrive at practical results. We are in hopes that Mr. Gilhooly will call on you again, and that your reporter will be as faithful in transcribing the conversation as he did the above.

INFLUENCE OF THE QUEEN.

HER MAJESTY, THE RULER.

OF late I have noticed that some have been speculating, or, rather, guessing, at the sphere or influence exerted by the queen. Some have said, that the swarming impulse was due to the influence of the workers, and that the issuing of swarms was also from the same source. I have no doubt but that these sayings have been to a very great extent the result of guesswork, or the theoretical speculations of those who never probed the matter very deep. Now, the word queen would be a term misapplied if it did not refer to a personage having power to rule; further, I do not believe that it would be an overstretch of facts were I to say that the entire creation, so far as animated nature is concerned, is governed or controlled to a great extent by a leading head or ruler. Take, for instance, a herd of cattle, and it will be noticed that some member of the herd invariably directs the course and footsteps of the rest. If they get into mischief, some particu-

lar member is the leader. This same principle can be traced from man on down to the insect-world. It seems to me, that at this stage of progression this question ought to be settled, although it looks at first sight as if it were a matter of but little practical utility; yet when we come to write out the minutiae, just such questions become important and oftentimes become the most difficult to answer. Now, I do not expect to be able to settle this question in the minds of all; but to those who doubt the influence and ruling power of the queen, let me say, go to a colony of bees 20 or 30 minutes before a swarm issues; place your ear to the hive, and keep it there until the swarm issues; then tell me the result of what you hear, and see if it does not correspond with the following:

1. The busy hum of worker bees, broken only by the piping of an excited queen. This state of affairs continues, and finally you hear a low, peculiar guttural sound, and simultaneously with this sound you will hear a great roar, and the issuing of a swarm is the order of the moment. Now keep your ear at the side of the hive, and you will hear the loud roar of the bees gradually subsiding; again will you hear the low guttural command of the queen, and again will the worker-bees pour forth with greater vigor, and this continues until the queen leaves the hive. When the order of march settles to a gradual quiet movement, you will no longer see the bees coming forth in gushes, at the command of their supreme ruler. The above applies more particularly to first swarms; after-swarms issue from a different impulse; yet the same command precedes all swarms of first or after origin. There are other conditions in which bees will swarm out or leave the hive in a body, where this command may or may not be heard.

Siam, Iowa, June 14, 1887.

R. B. ROBBINS.

On one occasion, several years ago, while we were standing at the entrance, in front of the hive, we heard a sharp piping of the queen. It was long and continued. Immediately after, there was a rush for the entrance, and a large swarm issued. On other occasions we have stood at the entrance of hives, immediately prior to and at the time the swarm issued, but did not hear the sharp note of the queen. Both of these instances were with first swarms. In the second case the queen may have uttered a sharp note; but certain it is, we did not hear it. We should be glad to hear from others as to whether they have noticed this singular phenomenon before the issuing of swarms.

A SHORT STORY WITH A MORAL, IN TWO CHAPTERS.

CHAPTER I.—BLASTED HOPES.

THE best imported queen you sent me arrived safely; but while introducing her she flew off the frames and I have not seen her since, although I left the hive open an hour, thinking she might come back. If she entered one of the seventy stands we have, I shall never be any the wiser. If you have another best imported queen as nice as this one, please send her at once.

MRS. A. F. PROPER.

Portland, Ind., July 5, 1887.

Now, none but those who have passed

through a similar experience can realize just how our good friend felt at the loss of that select imported queen. Imagine, if you please, six dollars or more taking wings and flying away right before your face and eyes; and to add to the disappointment, the queen happened to be one that exactly pleased, so far as looks were concerned. Did you ever have a queen that just suited you to a dot—so much so that you felt like saying, "There, I would not take a ten-dollar bill for that 'lady' just as he stands there on the comb"? Then to have her missing is one of the most perplexing and provoking things I know of. This story, however, was to have two chapters, and I take great pleasure in presenting you now with chapter two.

CHAPTER II. — BLASTED HOPES DISPELLED, AND BRIGHT HOPES ENCOURAGING TAKING THEIR PLACE.

I ordered another queen of you this morning in the place of the one which flew away while introducing, July 1. I had a swarm come off in the morning of that day; and while cutting out the cells one young queen hatched, but the next day I found her dead in front of the hive. This afternoon I thought I would look in and see what was the matter, and give them another cell. I was astonished to find eggs in several combs, and on looking further I found my imported queen, as large as life, and apparently very much at home. I know I can not be mistaken, for I noticed particularly when the queen arrived, that she had the point of the right wing clipped off a very little in a rounding manner, and her shape seems a little different from the rest of my queens. She is in another part of the apiary altogether from where I introduced her, and the surroundings are not at all alike. I hope you will not have sent another when this reaches you, for I can not make use of two imported queens, and there is no one here to whom I could sell such an expensive queen. This will reach you by the next mail; and if you are not *very* prompt, I think it will reach you in time.

MRS. A. F. PROPER.

Portland, Ind., July 5, 1887.

Now, then, friends, if you know what it is to feel keen disappointment you may also know what it is to feel real pleasure. I have sometimes thought that it is only by these strong contrasts that we are enabled to take in, to the fullest extent, the pleasant things of this world. He who has never known sickness knows not the joy of full health; so it is only he who has known loss that can feel, to the fullest extent, a thrill of success. If our good friend is not light-hearted, I am no judge.—Now one word in regard to queens getting into other hives. There is oftentimes something very strange about the way they turn up in unexpected places, and I have been able to explain it only by supposing they crawled or hopped about at random until they accidentally came near enough to hear the hum of some hive. Being attracted by this they crawl in, sometimes to be stung to death, but very often to be well received, and supplant the reigning queen, as in the above. A laying queen will almost always receive the preference over a young queen that has not commenced to lay; and this is a hint in introducing. We can nearly always let a laying queen right loose in any hive where there is

a young queen recently hatched. Luckily for our friend, our imported queens were out, and we were waiting for another shipment, or we should probably have made trouble by our usual promptness.

THE TWO-PART SUPER.

SUGGESTIONS ON THE CONSTRUCTION OF SUPERS, FROM J. M. SHUCK.

WITH the aid of the cuts, little description is needed. The sections are set in one half, and the separators between the end sections in the rows, and the supers are slipped in, then the other half of the super is slipped over the sections, and the two parts locked together by the clasps shown at the ends of the case. The T supports for the sections are made either by nailing metal strips to the outer edges of the partitions of the rows of sections, or wholly of tin, as shown in the engraving. The T rails in this

SHUCK'S REVERSIBLE SUPER.

super are nailed fast in their places, and the super is made very stiff and serviceable. With proper use it should last fifty years or more. The blank tops and bottoms to the sections shown in the cut are to keep the tops and bottoms of sections clean, and they serve the purpose admirably, as the sections come from the super cleaner than they can be scraped after coming from any other case I ever saw. The super may be used either with or without these blanks. The separators at the ends of the rows of sections prevent the bees from propolizing the super and thus fastening the sections; and the super is slipped off the sections as easily, and in less time, than it takes to put the sections into the super.

With the tins for supports, separators the full length of the case may be used between the sections as well as at the ends of the rows of the sections. Full bee-space is provided at the bottom and top of the super, and the super is invertible without any adjusting, fussing, or tinkering. J. M. SHUCK.

Des Moines, Iowa, June 13, 1887.

LITTLE HONEY IN MISSISSIPPI.

HOW MANY DRONES MAY BE CAUGHT IN A DRONE-TRAP.

MY bees commenced well and early in the spring, but at present they are gathering but little honey. I commenced this spring with 6 colonies. I bought 3 in box hives, which I transferred into new hives. One colony, the Italians, cast a very large swarm on the 28th of April. Two black colonies cast swarms on the 29th. The same two blacks cast swarms a few days later, making 5 new swarms. None of the others have swarmed, and I believe they have given up all idea of swarming, as they went to work killing off their drones. One of the colonies I bought I did not transfer until May 26, waiting for them to swarm out; but they seemed to have an oversupply of drones, so I set my Alley drone-trap in front of it two evenings, and myself and wife counted what we caught, and were surprised to find we had about 2200, and there still seemed to be plenty, which the bees went to work at and are killing.

I have taken off in 1-lb. sections, about 300 lbs.

I sent and got an extractor, and thought to use it; but as the honey-flow slacked off I have not done so.

I learned, a few days ago, that friend Gentry's bees were dying, and that he said from starvation. He had shipped some honey in barrels, so he ordered it sent back to feed his bees with. I understand that another gentleman at Beulah was losing his bees in the same way. They have their apiaries some 7 or 8 miles apart, on the east side of the Mississippi River, while my own is located on the west side, and near the river. Mine are in a densely wooded country. I have sold what honey I have had so far at home, or at our little county seat, at from 12 to 15 cts. per section. My neighbor bee-keepers run for extracted honey, and generally ship in molasses-barrels, and get but little for it.

WHISKY VERSUS BEE-STINGS.

On Saturday, June 4, a negro man in the neighborhood (Henry Wilson) having, a few days before, found a bee-tree, concluded that he would cut it and get the honey; so, filling himself with whisky he cut the tree and went straight in to where the bees were. They covered him up. There being a bayou of water close at hand, he sprang into it, thinking thereby to get clear of the bees; but, not so. They still clung to him. His companions got him out, but before they could get the bees off from him he was dead. Thus you see bees and whisky will not work well together.

R. J. MATHEWS.

Riverton, Bolivar Co., Miss., June 23, 1887.

Friend M., I do not want to have anybody think I am glad to hear that any one is dead; but when I saw your heading I was a

little afraid that you might have another item recommending whisky as a remedial agent for bee-stings; but I am just fanatic enough to prefer not to have reports of that kind, even when appearances indicate that whisky saved a life. Better let a man die occasionally than to start so many to drinking because "the doctor advised it." Well, you see your report is just the kind we wanted. This colored man got full of whisky, evidently with the idea that it would counteract the poison of the sting. It did not, however, and he died. Perhaps we can't tell exactly whether it was the whisky, the stings, or the water, that killed him. But this we do know pretty surely—if he had not taken the whisky he would not have died. In regard to selling off the honey so as to let the bees die, I would advise your friends not to extract quite so closely. Leave a pretty good supply in the brood-chamber.

CELLAR WINTERING AND OUTDOOR WINTERING.

FRIEND POPPLETON CONSIDERS A STRONG STATEMENT IN MR. HUTCHINSON'S NEW BOOK.

FRIEND ROOT:—On the first page of GLEANINGS for June 1, appears a review of a letter of mine to friend Hutchinson. The differences of views between friend H. and myself are on subjects of interest to bee-keepers; and a further discussion, not controversy, may be wise.

In figuring up the cost of cellar wintering, friend H. has only, it seems to me, given the shell and left out the kernel of the matter. He has allowed nothing for the wear and tear, and even a cellar won't last always without some work and expense on it, and he has made no calculation whatever for care and supervision of the cellar while the bees are in it. I have had but little practical experience with cellar wintering, but have always understood that the best-constructed cellars had to be watched more or less during the winter, to preserve proper temperature, etc. Nearly all persons with whom I have at times talked, who have wintered bees successfully in cellars, have insisted on the necessity of keeping fires in the rooms over the bee-cellar all winter. This supervision, if really necessary, as I am led to believe it is, is really much more costly than all the items enumerated by Mr. H.; and, above all, it is one of the things which can not be trusted to any one except the master himself.

During four different winters I have been away from my bees (in Florida) from about Dec. 1st until the latter part of March, and later. I should not have dared to risk this, had my bees been in any ordinary cellar, such as could have been built for less than three or four times the cost of those he bases his arguments on. This being free to do something else in winter has been worth many times over the value of the 200 or 300 lbs. of honey that cellar wintering would have saved me. I still think that the amount saved by cellar wintering, all things considered, is too infinitesimal to be taken into account.

Friend H., your explanation of what you meant by a "perfect system" only makes it worse than

before. The truth is, that no system can be called *perfect* until it has proved its perfection by several years' trial and success by many different persons in different localities. Many of us older heads have supposed that we had found the royal road to success, and would reach it, too, for a series of years, when some climatic or food changes would occur, and the goal would be still ahead. In your quotation from Prof. Cook, I see two "ifs," and *perfection* contains no "ifs." Neither do I think that the professor is right in his opinion that chaff hives are not safe in severe winters, *if properly constructed and handled*. I think they will be found fully as safe as cellars, but wintering in cellars is much the best understood by the majority of bee-keepers, and it ought to be, for it has been practiced and experimented with about four times as long, at least, as have chaff hives. I venture the prediction, that neither of us will live long enough to see a perfect system of wintering in that Northern climate.

My reasons for saying what I did about your management not being adapted to outdoor wintering was based on my own experience. For several years, almost the only losses I had were among the half-dozen or so colonies that I had worked on the top-story plan. I could give my theory why I think such colonies wintered poorest, but I don't think it is worth while to take up the space, as the production of comb honey compels that method of management; neither is it necessary to point out the very obvious reasons why your neighbor, Mr. Donane, failed with chaff hives.

Friend H., an "experienced apiarist" is the very one who can make it pay to take time to practice spreading brood, especially so as this work comes previous to the honey season when one *has time* to care for, including this work, at least four times as large an apiary as he can care for during the honey season. It is when one takes into consideration how "to secure the greatest amount of honey with the least expenditure of capital and labor" within a given field that we see the need of doing every thing in our power to increase the average products of our colonies; and spreading of the brood is valuable, partly because it comes before the real working season is on us.

No, the taking of honey from the brood-nest is *not* one of the things of the past, nor is it likely to be soon. For several years I worked a few colonies on the double-story plan, on purpose to test this matter of which was the most profitable to use, and I came to very decidedly prefer the single-story plan for extracted honey. I also watched my neighbors quite closely, and those who used that plan succeeded best in both getting honey and in wintering. The question of "best food for winter" opens up the very important subject of what is good honey for wintering purposes, which is too important to be put off to the end of a rambling article on other matters. I have never seen any thing yet on that which fully meets my views, although it lies at the very foundation of successful wintering. I have often thought I should like to add my mite to that subject, but ill health has so far prevented.

I can not understand by what reasons Mr. H. has arrived at the conclusion that it is profitable to feed sugar-stores when raising comb honey, but not when producing extracted. It seems to me that the same rule applies to both in this respect.

So far as the comparative value of Italians and

blacks is concerned, I suppose Mr. H. and myself will continue to agree to disagree, we having arrived at different conclusions in that matter. To do justice to ourselves would require an entire article for each of the different topics discussed by us; but time and space forbid. It will be noticed, that these topics are all side issues from the main one treated of in Mr. H.'s book. A friendly discussion is necessary to bring out the true facts and theories of our chosen pursuit; but it is worse than folly to conduct it in any other than a fair and kindly manner. We should always bear in mind that others have the same right to their opinions that we have, and that possibly they may be right and we wrong.

O. O. POPPLETON.

Hawks Park, Fla., June 27, 1887.

Friend P., it occurred to me that friend Hutchinson's statement in regard to cellar wintering was altogether too strong; but I thought best to let somebody else take it up. Our bees have wintered so well in chaff hives for a good many years past, we could hardly ask for any thing better. Now, if somebody were to ask me how much I should want to put all these bees in the cellar, look out for the temperature, ventilation, dampness, and all these other things, and then take them out in the spring and get them all right on their summer stands, I should very likely say I should not want to undertake it for less than 50 cts. per colony. It is true, we don't need to carry in those great heavy chaff hives; but in that case the combs must be taken out and put into lighter hives; then, as I usually want them in chaff hives again in the spring, they would all have to be put back again into chaff hives. We have a cellar already made and unoccupied; but to fix it for bees it would have to be darkened, arrangements made for sub-earth or some other kind of ventilation; doors and windows would have to be operated during our frequent warm spells in the middle of the winter, by opening them at night and closing in the day time, etc. I think we could winter our bees in that way, without any question, and very likely with considerable saving of honey; but one hundred dollars would be no temptation at all for us to go back to the old plan of cellar wintering, that we worked on years ago; and I feel quite sure that we should not save one hundred dollars' worth of stores. May be I have become stubborn in the matter; but when the bees do so well by letting them entirely alone, it seems to me I am excusable for being a little bit prejudiced against putting bees into cellars. Our variable Ohio climate, very likely, has much to do with our decision in regard to wintering. Ernest adds, that our 200 colonies did not consume, on an average, more than from seven to ten pounds of stores per hive during the past winter. If this be true, there could not have been a very great amount saved in the consumption of stores by putting them in the cellar. He also adds, that one hive, on which the chaff packing was omitted by mistake, consumed perhaps nearly double the amount of stores given above; so it makes a difference, you see, as to how our bees are fixed to go into winter quarters outdoors.

ITALIANS, CARNIOLANS, HOLY LANDS, AND CYPRIANS.

WHICH RACE IS THE BEST, AND UPON WHAT CRITERION SHOULD WE BASE OUR JUDGMENTS?

WE notice that the different races of bees have their champions, and undoubtedly they think they are really superior to the pure Italians. Now, if these claimed points of superiority over the Italian bee can be maintained by actual practice, then we must acknowledge the Italian bee is in the background; and the next point to arrive at is, which of the other races stands at the head, all points considered? It is claimed for the Carniolans, that they are the most gentle of all bees, do not gather propolis, are excelled by none as honey-gatherers, are better nurse-bees, breed up earlier in the spring and later in the fall. The champions of the Holy Lands have about the same story to repeat, and the advocates of Cyprian superiority will tell us, "If we know how to handle Cyps they are just as gentle as any other bees;" and some even go so far as to say they handle theirs without smoke, but do not say whether the bees make them smoke for so doing or not. The great majority tell us that the Italian bees are the best—first, last, and always, and with that class we stand; but we are ready and willing to accept some other bees instead, whenever their superiority is shown. Can breeders of any other race of bees show such yields of honey as have been produced by Italians? Will not the Italians breed up as early in the spring as need be, if they have been wintered as they should be? And, again, will not the Italians breed up just as late in the fall as the season will really warrant them in doing? Is it any extra quality, when any race of bees will breed excessively in season and out of season, as it is claimed the Carniolans do? and is it any point of superiority when we say they will not gather propolis? If so, why is it, and how is it? A breeder of Holy Lands states one point where his bees are better than the Italians, and we certainly believe it, if it is true; and that is, the Holy Lands never sting any one when they are astray, but the Italians are guilty of constantly prodding it to a person if he gets near them when astray. It is not perfectly clear to our mind just what is meant by the word "astray" when used in this connection. Is it the bees or the bee-keepers that are liable to get astray? We fear greatly that it is the bee-keepers who are guilty of such actions; and perhaps a real good healthy half-dozen Italians would do much toward bringing them back to the path of rectitude. But, letting this all pass, is there any one foolish enough to keep bees because they do not sting, or because they do not gather propolis? or because they are very prolific? We think not. We keep bees because we get our bread and butter by so doing, and for the pennies to lay aside for a rainy day; and now if there is any race of bees that will furnish us more bread and butter, and put more pennies in our pocket, they are the very bees we are looking for, and the ones we want to hear about.

Rochester, O., July 5, 1887. M. W. SHEPHERD.

Friend S., we think your remarks are right to the point. We keep bees for the pennies they may bring us. That race which, from its superior merits, can give us the most pennies is the one destined sooner or later to be our choice. From our own experience,

as well as from the multitude of reports which pass our eyes, we never yet have found a race of bees which would produce more pounds of honey than the justly praised Italians. That race of bees which will make a decided increase in our honey-crop from year to year will very soon crowd themselves among us. As long as the large majority stick by the daughters of sunny Italy, and their crosses, and so few, comparatively, say any thing in favor of the other races, we must concede the palm to the Italians.

MUTH-RASMUSSEN'S SUPER-SPRING.

VARIOUS MATTERS.

IN your foot-note to my article, p. 466, you ask: "Are we to understand that one spring is all you use to each division-board?" Yes, certainly. One spring is enough. The springs are quite strong, and it requires even some little force to push them down into place, if they are properly adjusted to the space between the division-board and the super. Experience will soon teach what tension is necessary. A button-hook might perhaps do to draw the spring with (I have not tried it), but it would be too small and short for replacing the spring. This can, however, be done by pressing with a small flat stick (as the side-piece of a brood-frame), or any other flat implement you may happen to have at hand, on top of the loop of the spring. I find that it hurts my hand to try to force the spring down without some such aid. The button-hook, if strong enough, might be carried in the pocket; but as my hands, when at work with the bees, are always more or less sticky with honey and propolis, I avoid as much as possible putting them in the pockets, and prefer having all the required implements in the tool-box, which I carry around with me.

To avoid misunderstanding, let me say to the readers of GLEANINGS, that in my original drawings I had represented the spring in the position which it occupies in the super. If you will turn the page around, so that the eye of the hook is up, you will have the correct position—and I think a better view—of the spring.

In my written explanations I therefore called the arm A "horizontal," which it will always be, when in use. The engraver has, however, turned the spring over on its side, and to correspond with this position the editor calls the arm A "perpendicular." Yet in the second column he uses the word "horizontal" twice. Here is where the misunderstanding might come in, as if the "horizontal" arm and the "perpendicular" arm were two different parts of the spring, while in reality they are one and the same thing.

Now let me object a little to your objection. While you admit that the device is quite ingenious, and perhaps the best thing that can be devised for the purpose, yet you cry out, "A little complicated," which is only a slight variation of your usual expression, "Too much machinery." Something must certainly be used to keep the frames close together, and what can be more simple and effectual than a spring which will adjust itself to slightly varying distances? You must acknowledge that it is a great way ahead of wedges, and also that it is much quicker adjusted than screws. The space it occu-

pies is too narrow to admit of drawing it out with the fingers, and therefore it becomes necessary to have a hook for that purpose. One hook is enough for each operator, and the expense for springs is only a trifle, besides being a permanent investment. In fact, they need not cost any thing, if you can find some old bed-springs, for you can make them yourself when you have leisure, and all the tools required are a vise, a hammer, and a chisel. If the springs should come into general use it might perhaps pay to make them by machinery; but then the trouble of many different sizes might arise. I therefore think it better that each one should make his own springs, using only the original shape as a pattern.

Let me here say, that the super-spring is not intended for reversing-arrangements. For such you must use something that can not slip, and here the screw is perhaps the best implement.

TO GET THE LAST SECTION IN THE T SUPER.

On p. 460, Dr. Miller speaks of the difficulty of getting the last section into the T super. I have never, as yet, seen the T super; but from the descriptions I think I can form a pretty correct idea of what it is like.

Let me suggest, that

the doctor try the implement here illustrated. A strip of tin, *c a*, 26 inches long, is cut off, the width of a section, and bent in the shape of the letter U. In the bend is fastened a semicircular block of wood, *a*, as thick as the width of the tin, and with a diameter of $4\frac{1}{4}$ inches, or a little over. The U is placed upside down on the T tins, between the two adjoining sections, *b b*, and the last section, *c*, is slipped into the top of the U and pushed down between its smooth sides, where it will have nothing to catch on. When the section is in place, without drawing the U.

"Too much machinery," I hear you say again. Well, let the doctor try it and report. If it does not give satisfaction, there is not much loss.

ABOUT ILLUSTRATIONS.

There is no doubt that illustrations are a valuable aid to the full understanding of much that we read. I shall soon give a description of an excellent and cheap home-made camera-obscura, with the help of which any one can easily illustrate what he wishes to describe. The artist's camera which you advertised some years ago, and which I bought of you, is too small, and necessitates transferring the picture; while with the one I have in view, you draw directly on the paper, and on a larger scale, which will be easier for most artists. WM. MUTH-RASMUSSEN.

Independence, Cal., June 27, 1887.

I plead guilty, friend M., to the charge that I so often make, of complication, or too much machinery; and that is just exactly what I should say of your invention figured above; that is, it seems to me I would rather get along without it than to have it around. But I might be mistaken, if I made it my regular business. Ernest says he has been bothered to some extent by this very matter, and there is no question but that your device will work every time. Will the friends who make a trial of it please report?

WINTERING BEES.

J. E. POND'S EXPERIMENTS.

WHY is there such a difference in the results from wintering our bees? One is uniformly successful, while another loses a large percentage, if not all, although in practically the same locality, and under the same climatic differences. I am led to ask the above question by reading of the ill luck (I suppose) of many in the same situation as regards climate as myself, while I have not lost a colony by reason of the weather for over 16 years, and wintering, too, on summer stands. With this question in my mind I prepared my bees (ten colonies) last fall for the purpose of experimenting. Some were in chaff hives, some in double-walled hives with dead-air space, two in $\frac{3}{8}$ -inch, and two in $\frac{1}{2}$ -inch hives, and all on Simplicity L. frames, $17\frac{1}{2}$ long and $9\frac{1}{4}$ deep. They all came safely through, and in excellent condition, with but little difference in strength, although with considerable difference in the amount of stores consumed; and, strange to say, a colony in a chaff hive consumed the most, and one in a $\frac{1}{2}$ -inch-thick hive the least; and this, too, by careful weighing on the same day in fall and spring, $21\frac{1}{4}$ lbs. being the most consumed, and $8\frac{1}{2}$ lbs. the least, from November 11th to March 5th, each colony being as nearly like every other in the fall as ten hives could well be made, as regards strength and stores, and all being hived on nine frames in a $14\frac{1}{4}$ -inch-wide brood-chamber.

Some of these colonies were kept in two-story hives with full access to every part. Some had a Hill device over the frames, the others having an inch or more space over the tops of frames, given by putting on a rim about an inch deep covered with common burlap. All the hives were given full width of entrance, and all had 5 or 6 inches of forest-leaves packed moderately hard on top of the frames, over the covering quilt made of burlap, top ventilation being given by boring a two-inch hole in each end of the cover. The colonies were all prepared alike, except the difference mentioned in the hives, and all had a southern exposure, with a thick hedge $6\frac{1}{2}$ feet high on the north and west sides. The brood-chambers of all were prepared as follows:

Nine frames, the upper halves filled with sealed stores; none in the lower half; in November the hives were all examined, and the clusters forced by changing frames to the west side of the hives. Those wintered in two-story hives had three or four frames of honey in the upper story, the rest being empty. The queens in these were confined to the lower story, the workers having access to the upper, if they chose to go there, which they did, and from which they transferred all the honey.

My deductions from the above are, that cold does not kill our bees, and that, if the hives are so prepared that the excess of moisture is so disposed of that it can not freeze in the brood-nest, there will be no trouble with bees dying in winter, or dwindling, or being depopulated by diarrhea in spring. In the matter of stores, the cells were practically all sealed, and pollen was distributed through the hives as it ordinarily would be in the fall, none of it being removed when being prepared for winter.

If this immunity from loss in my apiary were but a single instance, I should deem the matter one of

chance and good luck only; but when, with the same form of protection, I obtain the same results year after year, I have the right to think and believe that I have solved the winter problem, and the best of reasons for making no change in my wintering method. I can but say, that the "bridge that carries me safe over" will probably carry others safe over also, and I advise them to do as I have done, this coming fall. One thing, however, must be understood: I am particular in preparing my bees in precisely the same way and manner each year; and while a different plan may be equally safe, I can only advise doing just as I have done, as a change may bring different results from those I have invariably found to follow my own course of procedure.

This wintering question is the most troublesome one we have. Settle it, and bee-keeping is placed on a sure and certain footing. If any try the method outlined above, I should like to have them report next spring the results they find, stating full particulars at the same time.

J. E. POND, JR.

Foxboro, Mass., June 27, 1887.

THE PIPING OF QUEENS.

CELL-PROTECTORS, ETC.

ON page 462, GLEANINGS for June 15, I see Mr. Dewey thinks Doolittle is not correct regarding the piping of queens, and after-swarms, as I gave on page 434. Bro. Dewey says: "I most emphatically deny that there is only one queen allowed to leave the queen-cells at a time, or that only one pipes at a time, or that, as a rule, only one queen accompanies the second, third, or, in fact, any after-swarm." Now, friend Dewey, won't you please turn to page 434 again, and read carefully and see if Doolittle said any thing to conflict with your views, or made any assertion to the effect that *only one* queen piped at a time, or that *only one* queen accompanied after-swarms? I have carefully read my article over, and do not see any such assertion made. No one can say all that could be said on any subject in one article; and as it is necessary to condense matter as much as possible, to give to all room in GLEANINGS for a few words, I do not go over all the ground of the past, many times, in order to be brief. All who have read my writings in the past, know that I believe that more than one queen pipes at a time, and that more than one queen goes with after-swarms; and, to make all plain to new beginners, I will say this in addition to what is written on page 434: A queen pipes only when there are other queens (*in cells*) in the hive, of mature age. To make it a little plainer: A young queen may mature and hatch two or more days before any of her rival sisters come to maturity; but as far as I have observed, she rarely if ever peeps till some of those sisters come to maturity. As soon as this occurs, the first hatched seems to get in a rage and begins to peep; and in from six to eight hours after maturity, although kept back in the cells, these rivals begin to peep, often half a dozen answering (the one having her liberty) at a time. These queens being in their cells give off a kind of muffled sound, so it is easy to tell their peep from the one which is out. I spoke only of the liberated queen as regarding piping on page 434. This is plain, is it not, friend Dewey? Well, when second swarming commences this queen that

has had her liberty all the while, leads, or is about the first bee out, often flying back and forth several times, as if to urge the bees out. In the hurry and bustle of swarming, the queen-cells are left to themselves for a time, and one or two, sometimes more, of the mature queens I have spoken of, hastily finish biting the cover of the cell off, and get out with the bees in the air before the guards in the hive realize what has happened, so that two or three queens with a second swarm is quite a frequent occurrence; but it is a rare thing to find more than three with such a swarm. Now, if a third swarm is to issue, the guards collect about the cells again, allowing one queen her liberty, and keeping the rest in their cells. If more than one are out in the hive, all are killed but one; for queens at liberty with the bees intent on swarming, soon get together and all but one are killed. At third swarming there are fewer bees and more mature queens, as a rule, than at the time of second swarming, so that, when the cell-guards become "routed" by the hurry and bustle of another swarm, more queens leave the cells, so that I have known as many as from 12 to 20 queens with a third swarm, but rarely more than from 2 to 5. Thus you will see "we two D.'s" agree pretty well finally, after the rest of the story left untold on page 434 is brought out.

Now, what I do claim, which many of the brethren don't seem willing to admit, is, that queens at maturity are white-looking, feeble things, and can no more peep nor fly than a newly hatched worker; and all queens which can fly at hatching matured from eight hours to a week before, but were kept back and were fed in the cells by the guard-bees. Who ever knew a queen which had just cut through the covering to her cell, in a queen or lamp nursery, to be able to fly? If any one ever did, then I am down. If not, those opposing may well investigate.

QUEEN-CELL PROTECTORS.

Before closing I wish to say a word or two about those queen-cell protectors, spoken of on page 482. I see Ernest and the apiarist are not having success with them. I can not understand this, for many very flattering reports come to me from those using them, and I have not had a single failure from the first cell tried, some two years ago, till the present moment. The sample protector sent me has been in almost constant use for the past six weeks, giving birth to queen after queen, with a certainty which only those can appreciate who in years gone by have had cells by the dozen destroyed. The cell is pushed down in the apex of the cone as far as it will go, so that there is barely room for the cover of the cell to come open when the queen bites it off. I said I had not made a failure, by which I meant that in no case had the queen been destroyed before maturity. Where such a caged cell is put in a full colony for the purpose of superseding a laying queen, if the bees think their old queen doesn't need replacing they kill the young queen and drag her out at the entrance. I use only cells that will hatch in from 6 to 36 hours in the cell-protector. Perhaps using too "young" cells may be your trouble.

G. M. DOOLITTLE.

Borodino, N. Y., July, 1887.

You may be right, friend D., in your last suggestion. At any rate, when we were using the cell-protectors there was an almost entire lack of honey, and the bees were more

than once on the point of starvation. At such times they seem determined to tear down queen-cells. There have been so many favorable reports in regard to the queen-cell protectors, that we feel sure we must have made some mistake somewhere. On account of foul brood being in our apiaries we can not raise any more queens this season, and consequently are not able to test the protectors. We hope to make a further trial next year.—In regard to the piping of queens, if you will turn to page 537, current issue, you will see that there is still another D. discussing this same question. D. No. 3 says D. No. 1 and No. 2 are both right, as you state.

HEADS OF GRAIN FROM DIFFERENT FIELDS.

FALSE STATEMENTS IN REGARD TO LIQUID HONEY.

THE boss of the printing-office hands us the following, which he cut from the *Cleveland Leader*:

An authority on canned goods reveals the interesting fact that most of the jellies in the market are made of apple-parings and cores. Sometimes the stock is kept so long that it will not make jelly, then they make strained honey out of it. —*Philadelphia Surgical and Medical Reporter*.

Friends of the *Philadelphia Surgical and Medical Reporter*, and newspapers in general, we beg to contradict your report. We don't know about the jelly part of it, but we are inclined to think it is as untrue as the part is in regard to honey. Nothing like even poor honey can be made from apple-parings and cores; and inasmuch as there is scarcely a town or village now in the United States where good pure honey is not kept on sale by some honest bee-keeper, we insist that the whole story is an impossibility. People are too well posted to be humbugged in such a way, even if the world is bad enough to do it. There may be poor honey occasionally put on the market; but the sensational scare, that it is made of stale apple-parings and cores, is an untruth. We should be glad to be told where any such article is kept for sale.

A LETTER FROM AUSTRALIA; THE DOOLITTLE METHOD OF INTRODUCING QUEENS A SUCCESS.

We have been introducing queens by Mr. Doolittle's method, and have always found it to succeed to a marvel. There is no doubt, that in making his plan known to the public he has conferred an immense benefit on bee-keepers, which I think they should acknowledge in some practical form. I may say, too, that J. W. Garrett tells us he has tried it, and never found it to fail. We introduced a laying queen two days ago, and in eighteen hours found her laying, and the bees working away not ten yards from their old home, as if they had been there all their lives. All our first experiments were with virgin queens, all of which we found laying at the end of the week. In December last I wrote to D. Stroud, of South Africa, about the South-African bees, and asked him for a list of his prices. We did not take the *British Bee Journal*, nor know of any one who did; but, strange to say,

we have had no reply from him. As we are only 21 days post from the Cape, there has been plenty of time. Again, last month I wrote, sending him two black queens in a Benton mailing-cage, as an experiment, to see whether they would reach him alive, and to show him the kind of cage now in use. From his communication to you he did not appear to know very much about some of the late inventions. We have lately been considering whether the Italian bee is really best suited to our part of the world; here our principal honey crop (from the eucalypte) comes to us in the autumn, and, except in the orchard or clover districts, the bees scarcely do much more than make a good living in the spring and summer. In an old number of *GLEANINGS* which was sent to me, I noticed that exception was taken to some race of bees because they spent their spring months in brood-rearing, instead of honey-gathering. Now, it seems to me that this is just the bee we want, so as to have our colonies strong, and in full working order by the autumn; but I have forgotten which particular race of bees it was. Will you give this matter your best consideration, my dear Mr. Root? bearing in mind that our climate is, as a general thing, a very dry one, and that we are not obliged to winter our bees, and let us know which you think would be the best race of bees for us. T. F. BRADLEY.

Campbelltown, N. S. W., Aus., Apr. 18, 1887.

The bees which you probably have in mind are the Holy-Land bees. They will satisfy you in the amount of brood. As to where they may be found, see our advertising columns. It is pretty hard to say which would be the best bees for your locality. As a general rule you will not find a better race than Italians.

FOUL BROOD, TO CURE.

Your favor of the 18th inst. is at hand, also the A B C of Bee Culture. I am satisfied your method of treatment of foul brood, as so admirably detailed in your very recent issue of the A B C, would be eminently satisfactory where this dreadful disease is in its incipient stages, and when its presence is the result of bees having access to honey from colonies so affected. The conditions of my colonies, and the sources whence it comes, are such as to render any thing but the most persistent, thorough, and heroic treatment worse than useless. The development is rapid, and of a most positive and unmistakable character.

Now, here is our method: Cage all the queens for, say, 20 days, to stop brood-rearing. Confine the bees in cages from 24 to 48 hours until their honey-sacks are exhausted. Boil thoroughly and repaint the hives. Beeswax all the combs, and destroy frames. Move the bees $\frac{3}{4}$ miles in the country, and put on new frames and full foundation. Now, friend Root, do you think this would eradicate the disease? The destruction of the hive involves too much expense, if we can possibly avoid it. The work of renovating will commence as soon as basswood flow ceases.

Eureka, Ill., June 21, 1887.

S. W. LAKIN.

The plan which you propose for curing foul brood, I think will work all right. While there would be considerable advantage, perhaps, in caging queens for a period of 20 days to prevent brood-rearing, yet our experience has repeatedly shown that the starvation plan (that is, burning the brood-combs, and placing the affected bees and

queens in clean hives on frames of fdn., and boiling or steaming old hives) is entirely successful so far as the colony treated is itself concerned. Your suggestion in regard to taking bees, as fast as treated, to an entirely new location, is good; and where you can do this without much expense, I would advise you to do it. You will then have all the colonies treated, away from the baneful influences of bees intermingling, and carrying honey from infected colonies into the newly formed swarms.

ANOTHER DEVICE FOR OPENING SCREEN-DOORS.

You ask in GLEANINGS, May 15, for some improvement or simpler arrangement of J. A. Green's screen-door opener. Well, here is mine. Make a roller a little longer than the width of the door; fasten it just under the door with two brackets, at the end near the door-binges; fasten to the roller an arm projecting up. An end of an old steel wagon-spring is good. At the other end, and clear from the door, have another arm raised a little above a level, then by pressing this last arm down it will turn the roller, and the other arm will open the door; thus:

FRADENBURG'S PLAN FOR OPENING SCREEN-DOORS.

I use no cord, no pulleys; nothing unsightly; it can be so balanced that it will not hinder the door from closing.

A. A. FRADENBURG.

Port Washington, O., May 23, 1887.

FATHER LANGSTROTH, AND WHAT A NEIGHBOR SAYS OF HIM.

In GLEANINGS of June 15, C. F. Uhl makes this inquiry. "Was there ever any patent on the Langstroth hive? If so, who was the patentee?" Now, for the information of friend Uhl and others, I will state that the Rev. L. L. Langstroth received letters-patent on his movable-comb hive, Oct. 5, 1852. Reissued May 26, 1863, and I think a further extension afterward; and as to his being a fraud and swindler, nothing could be further from the truth. After almost 30 years' acquaintance with him (I can fully indorse all you say of him) I have always found him to be an honorable and truly Christian gentleman; in fact, one of "the salt of the earth;" and though it has been his lot to be sorely afflicted, the reason *why* we can not tell; but, "Shall not the Judge of all the earth do right?"

Oxford, O., June 27, 1887.

J. COULTER, SR.

WHY DO MY BEES SWARM OUT AGAIN?

Myself and neighbors have been troubled a great deal with bees leaving the hive after having been hived for from three to ten days, and having brood well started, and no visible reason for their doing so. Thinking that perhaps others had been troubled in the same way, your advice might be of interest. I have tried both chaff and Simplicity hives, with and without brood given them when hived,

and single and double swarms, and there is no apparent difference, and they frequently come out two or three times, but always cluster and finally accept the hive and stay. They invariably have brood if they stay long enough to start it.

M. E. KIMSEY.

Salem Center, Ind., June 24, 1887.

Friend K., your experience is very unusual indeed; in fact, we have always laid it down as a rule, that bees never swarm out after they have commenced brood-rearing. I think it is a sort of mania that they have gotten into, and that you will not be troubled with it very long. Bees sometimes get into such ways of doing, and the whole apiary seems to be for a time infected with this kind of behavior.

WHEN TO CUT ALSIKE FOR SEED; DOOLITTLE QUEEN-CELL PROTECTOR.

As alsike clover is gaining rapidly in favor with farmers as a hay and pasture crop, especially on suitable soils, and is also one of the best honey-plants, perhaps the experience of one of our most successful growers here will be of use to many. He is the one who harvested the 12-acre crop last year. His name is H. E. Wilson. He has raised alsike for many years. He sows only two quarts per acre, and prefers sowing in the fall, drilling it in with wheat. He harvests the seed crop when in the best condition for hay, when the stalk, leaves, and some of the last blossoms are yet green. He says he gets more seed than when riper, besides a good crop of hay. His 12 acres yielded almost 6 bushels to the acre. He sold the big load for \$6.25 per bushel; the rest at retail for \$7.00. Mr. Conrad Atwell and A. D. Macham, of this place, will harvest seed, and probably many others. Mr. Macham has pastured his this spring, in order to delay the harvest, as it generally comes in the midst of the wheat harvest. His crop looks promising now.

THE DOOLITTLE QUEEN-CELL PROTECTOR A SUCCESS.

I made a queen-cell-protector mold according to your directions. My block is three inches thick. I cut a shoulder on all four sides of the block $\frac{1}{2}$ inch down, leaving the face of the block just the size of the piece of wire cloth for the protector, which helps to place the piece on evenly and quickly over the mold. I have used the protector for 12 queen-cells, and have failed with only one, and that looked as though it was destroyed by a worm. I make the hole in the point not very large, and see that the point of the queen-cell fills the hole. The queen-cell protector is a great help to me, as I am dividing many colonies of bees.

H. S. HOXIE.

Holloway, Mich., June 24, 1887.

THE BEE-ROCK.

The bees, up to the present date, have gathered but little honey, and have made no surplus whatever. They have plenty for brood-rearing, but have never swarmed any. The imported queen I bought of you last July has been very prolific this season. I have raised a great many queens from her. I see in the last number of GLEANINGS a sketch of what is called the "Bee Rock" in Tenn. I have often heard of that rock, and should like to hear further reports from it.

Webbville, Ky., June 24, 1887.

L. J. WEBB.

Every boy or girl, under 15 years of age, who writes a letter for this department, CONTAINING SOME VALUABLE FACT, NOT GENERALLY KNOWN, ON BEES OR OTHER MATTERS, will receive one of David Cook's excellent five-cent Sunday-school books. Many of these books contain the same matter that you find in Sunday-school books costing from \$1.00 to \$1.50. If you have had one or more books, give us the names that we may not send the same twice. We have now in stock six different books, as follows: viz.: *Sheer Off, Silver Keys, The Giant-Killer*; or, *The Roby Family, Rescued from Egypt, Pilgrim's Progress, and Ten Nights in a Bar-Room*. We have also *Our Homes, Part I, and Our Homes, Part II*. Besides the above books, you may have a photograph of our old house apiary, and a photograph of our own apiary, both taken a great many years ago. In the former is a picture of Novice, Blue Eyes, and Cuddy, and a glimpse of Ernest. We have also some pretty little colored pictures of birds, fruits, flowers, etc., suitable for framing. You can have your choice of any one of the above pictures or books for every letter that gives us some valuable piece of information.

CONDUCTED BY ERNEST R. ROOT.

THE BOYS' BEE-HIVE FACTORY.

GETTING READY FOR A BOOM IN BEE-SUPPLIES; THE HUMAN HAND.

ACCORDING to the advice of Mr. Green, the boys decided to postpone indefinitely their taking revenge on Jake. As honey would be soon coming in, he advised them to get every thing in readiness. The saw-mandrel and saws which they had sent for had arrived. The next thing to be accomplished was to construct a suitable saw-table; and as it requires considerable mechanical skill to make a good strong table, Mr. Green thought best to help the boys, as he had done on the windmill. He accordingly selected some pieces of hard wood at the planing-mill, and had it dressed out in shape to be put together. The two boys, with Mr. Green's assistance, soon had a good strong and rigid saw-table. This they located in the barn-loft, in position to be easily connected with the windmill. When at last every thing was in running order, as luck would have it, or, rather, "bad luck," as the boys were pleased to call it, there was not a breath of wind. They waited two or three days, and still no wind. On the fourth day there was a very little breeze, but hardly sufficient to keep the windmill in motion, even without the saw-table and connections.

By this time honey was beginning to come in. Mr. Green was needing some hives, frames, and supers. The boys had no lumber, and no capital to start with in the supply-business, and, worse than all, no wind; but Mr. G. readily consented to furnish them the lumber, and pay them a certain amount for manufacturing it into hives, supers, frames, etc. As to the wind, he enjoined upon them patience. He accordingly purchased at the planing-mill some selected white-pine lumber, planed on both sides, some of it $\frac{1}{2}$ inches thick for hives, and some $\frac{1}{4}$ inch for supers. After the lumber was

piled and sticked up in the barn-loft, the boys waited again for the wind. They could hardly wait, for there was nothing else that could supply them the requisite power. As it was hot summer weather there were only light breezes, and these were not sufficient to do them any good. Mr. Green told them they would have to wait until a thunder-shower should come up, and take advantage of the wind which might accompany or follow it. In the meantime, he gave the boys a little lecture on being careful with buzz-saws. Said he, "boys, you will never begin to realize the value of your fingers until you have lost one. No invention of man, however ingenious, has ever yet supplied us with what God has given us."

"Suppose, boys, that a man were to forget all about the use of hands, and should suddenly find himself without any. Let us then imagine that he has the power to have made on the ends of his arms any thing he pleases, for the purpose of doing the work of the world. The tool, if we may so call it, must be able to hold a hammer, pick up a grain of sand, play on the piano, hold a pen, repair a watch, open a hive, and, in short, do the entire work of the world. What do you suppose, boys, the hand would look like? How would you have such a hand made?"

The boys realized at once that such a problem could be solved only by an infinite mind, and they were silent. Jimmie looked at his hand, and seemed to see in it something more than blind chance.

"A human invention for the purpose of taking the place of the hand," continued Mr. Green, "would probably consist of a great deal of machinery; and even after the hand were done it would doubtless prove an entire failure; but God uses only four fingers, one thumb, five nails, nineteen bones, skin, and muscles; and yet in the human hand, our wisest men tell us, we have the highest exhibition of God's wisdom of any thing in the physical world."

"I never thought so before," said Sam; "but I believe that is all true—every word of it—for I find my hand is *just the thing* for all my work."

"A buzz-saw" continued Mr. Green, "does not seem to recognize the difference between a common board and your precious fingers. In fact, it seems to take special delight in mutilating and tearing to pieces some of the most wonderful pieces of work that God has ever made. You may think your little buzz-saw will not do a very great amount of damage; but a friend of mine who was running just a hand-power buzz-saw had his hand so mutilated on this same saw that he had to have it amputated. Now, boys, remember to be careful. Don't ever let your fingers get near a running saw. There is no need of it, and it is a terrible risk to run. To avoid any possible accident, I must insist on your using what sawyers call 'push-sticks.' They look like the little wooden pistols that the boys hold fire-crackers in. On the under side, at the muzzle end, a notch is cut, about half an inch square. The object of the notch is to catch hold of the lumber more easily and safely."

"Now, boys," said he, "in shoving lum-

ber through the saw, grasp hold of the handle of your wooden pistol. Should the saw strike the push-stick, it will do no harm. If you are handling small pieces, drive a wire nail just back of the notch, so as to project through. This nail will stick into lumber, and draw the pieces back so you can take off another slice. I omitted to say," he continued, "that the pistol needs to be made of seven-eighths pine, and the handle should be whittled and sandpapered so that no sharp corners project, otherwise your right hand will become blistered and sore." Mr. Green then left them to make their push-sticks.

The boys waited three or four more days, and anxiously watched Mr. Green's barometer, to see whether the mercury were falling. Mr. Green had told them, that when the mercury drops quite perceptibly in a short time, it indicates one of two things—either wind or rain, and probably both. If ever that mercurial column was watched by two pairs of eager eyes it was during the time that our two young mechanics were waiting for wind. The boys watched until it seemed as if there never was such a summer as that before. They argued, "If we don't get some rain pretty soon, the farms will all dry up, and there won't be any honey, and then, of course, nobody will want to buy hives of us." They felt almost inclined to complain again at the Creator of all things because he had not made a wind just when two little boys wanted to have him do so.

One evening, just before the boys separated to go to their respective homes, they noticed that the barometer indicated a storm. Mr. Green said that it might amount to something. The boys went to bed with expectant hearts. Along in the night, Sam heard his window-shutters rattle. He hastily put on his clothes, got his lantern, and started for the barn. On the way thither he was overtaken by Jimmie and his lantern. As they clambered up into the barn-loft, they said, "Now we will see if we can't make some hives; for if we don't take advantage of this wind we shall not be able to make any hives at all." "Hark! hear the big drops of rain patter on the roof."

JUVENILE LETTER-BOX.

"A chiel's amang ye takin' notes;
An' faith, he'll prent it."

HOLLYHOCK AS A HONEY-PLANT.

The bees are gathering a lot of honey now. They make most of the honey from sumac and cotton-bloom. The bees are making honey from buck-wheat too. How do you think hollyhock would do as a honey-plant? Bees get quite a lot of honey from it when in bloom. ELIZA MARTIN, age 11.

Hackett City, Ark., June 24, 1887.

Although the hollyhock has not been tested on a large scale, yet we are of the opinion that it would not amount to much as a honey-plant. We occasionally see a few bees hovering around the blossoms, but it seems to be the pollen they are after, rather than

the nectar. Are you sure that your bees gathered honey to any extent from hollyhock?

JOHN'S POETRY.

I saw in GLEANINGS several pieces of poetry about bees, so I have written one.

I have a busy little swarm
That works from morn till night,
And makes a person jump and scream
When they begin to bite.

Hlderton, Ont., Can.

JOHN G. KENDALL.

HERMAN'S LETTER.

Mypa's bees did not do well last season. It was too dry. Pa has an A B C book, and takes GLEANINGS. He likes it very much, especially the Home talks. I am in a hurry to know how Sam and Jim are getting along with their windmill.

HERMAN BLAIR, age 11.

Lockhart's, W. Va., Apr. 20, 1887.

HORSES STUNG.

Pa got ready to go to town last fall, and the team was left a few minutes, when the horses got started and upset the bee-hive. The bees came out and stung the horses. Papa ran out and ran them back up the hill to get the bees off. Two neighbors happened to be passing, and helped to get the bees off.

ROSA NAYLOR, age 14.

Lockhart, Jackson Co., W. Va., Apr. 5, 1887.

GLEANINGS AN OLD FRIEND.

Pa has 36 swarms, 10 new and 26 old ones. Pa told my brother and me if we would hive the bees when he was away he would give me twenty cents and my brother five cents. He went away, but no bees swarmed. We like GLEANINGS very much. Pa had not taken it in a long while; but when we took it again it seemed like one of the family.

Flint, Mich.

FANNY BOSTON.

A SWARM OF BUMBLE-BEES.

Pa packs his bees with chaff and straw on summer stands. He makes his hives of rustic work, with a shingle roof, and paints them red, white, and blue. While clearing land my brother Howard and I found 4 bumble-bee nests. We hived them all in a tin can, and got three queens. The fourth flew away. One of the queens killed the other two. They are doing well, considering there were but a few. I was stung on the finger while we were hiving them.

GEORGE C. ALLEN, age 11.

Snobomish, W. T.

CHILLED BEES.

Papa's bees made lots of honey last summer. The most of it was nice and white, and it was in one-pound sections. Papa traded some for butter, pound for pound. He sells the white for 12½ cts., and dark for 10 cts., in the neighborhood. Papa lost three stands of bees last winter, and mamma lost one. Some bees came out late one evening in the spring, and alighted on the peach-tree stump. We did not see them until the next morning. They looked as if they were dead. We brought them in to the fire, and brother Wesley put them in a five-pound cap with comb and honey, and they soon came to life, and they are the strongest hive on the place. Last summer they swarmed once, and filled 72 sections with honey, and had in the hive enough to keep them through the winter.

DAISY WHITE.

Broad Run Sta., Va.

HONEY-CAKES, PULLING OUT STINGS, ETC.

Father had 13 stands of bees last fall, and has only ten now. They are doing nicely. Mother makes honey-cakes. One of the recipes that father likes best is as follows: 1 cup of honey; 1 of sugar; 1 of butter; some milk; $2\frac{1}{2}$ lbs. of flour; scant $\frac{1}{2}$ cup of shortening; 1 egg; 1 large teaspoonful of saleratus; cinnamon and cloves, 1 teaspoonful of each. Bake slowly in two long shallow tins.

I have read, "Never pull a sting out, because when you get hold of it with your fingers you jam all the poison into your flesh; but squeeze it out and then you squeeze the poison out with it." I see king-birds have been written about twice in GLEANINGS. I will tell what I know about them. It was in the honey season that we noticed them. They would sit up on a high limb, frequently take a circle, and alight again with a poor little bee. Father got provoked and shot them and opened one. The bird did not have any bees in its crop, or, rather, we could not find any crop, but the gizzard was full of bees. My uncle, Albert Peck, living at Wheatfield, Mich., winters his bees successfully in the depot, therefore the noise, of course, does not affect them as some claim.

IVA A. PECK, age 14.

Jackson, Mich.

SECTIONS FOLDED AT THE RATE OF 1200 PER HOUR.

My brother Perl and I each put one-piece sections together at the rate of 1200 in one hour. We did not put that many together, but put up 20 in one minute, which is at that rate. We put them together Monday before noon, ready for use. It is pleasant work for us, and it might be we could do better. They were the sections which Fred got of you. Fred's bees have not swarmed this year, but are lying out considerably, and making lots of honey.

NETTIE H. CRANSTON.

Woodstock, Ohio.

Thank you, friend Nettie. Why, we feel as if we were acquainted with all the Cranston children. On p. 476 we offered to give any of the juveniles any thing they might choose from the ten-cent counter, providing they could beat the record of Alfred Higbee, who folded sections at the rate of $6\frac{2}{3}$ per minute. But here you have gone so far as to fold 20 in one minute—considerably more than $6\frac{2}{3}$ per minute, is it not? When I first read the statement, that you could fold at the rate of 1200 per hour, I thought it sounded something like a "fish-story." I accordingly took your letter to the lady who has charge of our sample-room; and when I told her there was a little girl down in Campaign Co., O., who could fold sections at the rate of 1200 an hour, she said flatly that it was impossible, and I almost felt inclined to think she was right. About the best record we had made in our sample-room was 750 an hour, and that was by one of the girls who had become quite expert. As we have some girls here who can fold as many sections as anybody ever did, I requested the one whom I thought could make the best record to keep count and see how many she could fold in one minute. To my surprise she folded 20 the first minute and 21 the second minute; but I tell you, she had no time for false motions. So we are obliged to admit, friend

Nettie, that the rate of 20 per minute is entirely possible; and if the sections were all piled on one side, and every thing in readiness, the 1200 for a whole hour *might* be made, providing the little girl or boy did not get tired out. Well, friend Nettie, as you have fulfilled the conditions we made on p. 476, please let us know what you choose from the ten-cent counter, and we will mail it to you.

OUR FRIEND L. C. ROOT; HIS OLD HOME, AS REPORTED BY A LITTLE GIRL.

This spring papa bought Mr. L. C. Root's place, half a mile from Mohawk, New York. We left Mickleton, New Jersey, on the 26th of March. The farmers there were planting potatoes. Arriving at Mohawk we were told there were six feet of snow in the woods, and we found good sleighing. All our goods were brought over from the station on sleds. It was some time before we saw a vehicle on wheels—every thing was on runners. We like our new home very much. Mr. Root had things fixed up very nicely, especially for bee-keeping. His cellars for wintering bees are complete. He and others had about 200 hives in the cellar last winter. We children were very much interested in seeing them take the bees out and work among them. Mr. Root did not wear any veil. The bees seemed to know when he came around. They never thought of stinging him, but they did the other men.

Mr. Root was here a week, getting his bees ready to ship. We became quite well acquainted with him, and found him to be a very fine man. We like him very much. We think Mr. Root must be sorry to leave his home here, as it is very cozy and comfortable. Papa has 60 hives of bees, 30 of which are in Simplicity hives. He bought 30 of Mr. Root. Mr. R. uses the Quinby hive. Papa's bees are doing well. They have been gathering honey from fruit-bloom. They are building up nicely. Young bees were flying to-day. He has a nice bee-yard to keep them in. In our old home, papa always wintered them on their summer stands. I think there was not a month during the winter but there was a day warm enough for bees to have a fly.

I am the elder daughter. I have one sister and two brothers. I am 11 years old. We go to church and Sunday-school. Two years ago I went to Sunday-school every Sunday in the year. My sister missed only one Sunday, being sick. We lived one mile from the church. Papa thinks you and Ernest write much alike. Oftentimes in reading an article he can not tell which of you wrote it till he sees the name.

HOPE L. HAINES.

Mohawk, N. Y., May 27, 1887.

A great many thanks, Hope. Your report of our old friend L. C. Root and his home is real good; and we believe there are many others who will bear you out in all the kind words you have said of Mr. Root. While a veteran reporter might have said a great many things in regard to Mr. Root's former home and surroundings which you have left out, yet when we want to get at little details—something that we all want to know—we must confess that the little folks carry off the palm. Your letter will be read with interest, and we think it deserving of a nice panel chromo, so we send you one.

OUR HOMES.

Ye are not your own, for ye are bought with a price.—I. COR. 6:19, 20.

BRO. ROOT:—I have long wanted an opportunity to say a few words to you, and now I have it. You have opened the way in *Our Homes*, p. 479. I have admired your zeal for years, but lamented that it lacked knowledge; i. e., the knowledge that you were cleansed from all unrighteousness. The work which Christ came to do is but half done in your case, for want of consecration and faith. You confessed your sins, and he pardoned you—yea, a thousand times and more, and now in this talk (*Our Homes*) you have confessed your unrighteousness, uncleanness, and depravity; now believe that he cleanses you from all unrighteousness. You received your pardon by faith, now receive your cleansing by faith, and hold it by faith—a continuous faith—no matter what the devil says about it. He is a liar. The blood of Jesus Christ his Son cleanseth us (continuously) from all sin (that is, the justified believer, who by faith applies it). Receive ye the Holy Ghost. He will satisfy your longings, and lead you into all truth and greater usefulness. You have made a fearful disclosure of your state (and yet I knew it all), for it is the state of carnality which can not be subjected to God; but it can be cleansed out by the blood of Christ. I know it!

Thank you, dear brother, for your kind admonition. No doubt you are in the main right; but, if you will excuse me, I am led to believe that we are not only unlike in our tastes and dispositions, but that we are, in many respects, in our religious experiences also. Furthermore, I am led to believe that God has different lines of work for each one of us to do. Perhaps he calls in different directions and in different ways. I know I have many temptations and many conflicts with Satan, and sometimes I have wondered whether it was because of my transgressions, or because God wished to take me through particular experiences, that I might be the means of leading others through like trials. May be both are true.

At one of our prayer-meetings, some years ago, I mentioned the fact that I had sometimes thought it strange that I should be so continually tempted and tried. After meeting, a good brother who was, by the way, a minister, suggested that it was not altogether improbable that it was well for me that I was tried in these different ways. Said he, "You have much in your life that might make you proud and overbearing. If the world saw no weakness in you, and you were aware of it, you might get to holding your head higher than you do now. Is it not possible there is a providence in this fact? and may not these things contribute to keep you humble? As it is, you constantly *feel* your need of Christ's pardoning power."

Since my last Home Paper there have been several letters similar to the one I have given above, and there seems to be some curiosity, and perhaps anxiety, to know in just what ways I have been tried. I have felt moved to give you one little incident as an illustration.

I have several times mentioned what I call my "Swamp Garden," within a quarter of a mile of our factory. Almost on the summit of a hill, there has been, since the recollection of the oldest inhabitant, a sort of bog, pond, or morass, inhabited by frogs, turtles, and snakes, and grown up with bushes and rank weeds. Even in the driest summer weather, water has stood there most of the time; and depths of vegetable mold, decayed leaves, moss, etc., extend downward many feet. During the winter the bushes were all cleared off, and the swamp nicely drained; and some time in May we were getting it ready for celery-plants. I was enjoying myself wonderfully in helping to get out the roots, logs, and various trash; and before I knew it I was dripping with perspiration. My underclothing had been all laid aside a few days because it was so near summer time. While at work I noticed a delightful breeze springing up from the northeast; but it seemed so delicious I paid but little attention to it, more than to thank God for that wonderfully bracing gift of cool fresh air, and for the breeze that sprang up in the forenoon to refresh the outdoor laborer. My friend, did you ever taste such a breeze when working in the cornfield, or when otherwise occupied in the open air? Pretty soon, however, the breeze became fresher and cooler, and I began to feel a kind of chill through my thin cotton shirt, the only covering for my arms and chest. I put on my vest, but I was chilly still; and as my coat was at the house, I thought I could not take any harm, as the sun shone so very warm. By and by, however, I began to think best to start for home and get a coat. I was chilly when I got it; but I reasoned that a warm coat, all wool, worn during such a hot summer day, would certainly fetch up the temperature soon; but as soon as I got home I was called to attend a funeral, and was assigned a place in an open doorway. I had by this time begun to dread that northeast breeze, and to wish it would not blow; but under the circumstances, and as the room was crowded, I decided to keep my place in the open doorway, rather than make any disturbance, even though I felt uncomfortably chilly all through the services. At dinner time I was given a place again near an open doorway, and I thought best to keep it, rather than to incur the confusion of changing places, when everybody was tired and hungry. After dinner I found I could not stand as much of a breeze from the open windows as many of the girls in the office, who often feel like complaining because I want the room so thoroughly ventilated during working hours. Just now, however, I begged to have the windows put down a little while. By this time it seemed as if nothing could warm me up, so I went home and got some hot lemonade, put on my overcoat, and afterward my winter fur cap. The temperature of my system, however, seemed to have got into a sort of falling way, and I kept getting colder and colder. By night time I was ready to be blanketed in bed, as friend Terry directed a few months ago. The blankets didn't seem to do much good, however. My teeth

chattered as if I had the ague, and a gathering in my head told me the old earache of my boyhood was coming, unless I had a hot brick under it. The Bath bricks used for warming feet nowadays are just the thing, and my good wife soon had one under my head, so hot it almost scorched the bed-clothing. I got warm, and into a sweat; but racking pains were darting through me all over, and I was a good candidate for lung fever, or something of that sort. The doctors can probably tell what the matter was. Some of you may be surprised that a man nearly fifty years of age should not have known better than to expose himself in the way I did. I did know better; but it had been some time since I had had a lesson like the above, and I was getting careless. I suppose that most of you have heard of lives being lost under similar circumstances. When you get heated up, and in a heavy perspiration, don't sit down in a draft to cool off. Take warning from the experience of Uncle Amos.

We are now ready for the spiritual teachings that came to me in consequence of the above imprudence. It has been many long years since I passed through the suffering I did that night. Sleep seemed to be impossible; and yet when my wife asked what was the matter, and where I was suffering, I could not really tell. Over and over again during the night I would sit up in bed and wonder whether I was made of *old boards*, *warped* and *checked* and *split*, or whether I was really flesh and blood, in my own home. The chill, or whatever it was, had left me light-headed; and even when I sat up I did not seem to know what I was or where I was. I simply knew that I was suffering in every part of my body, in a way I had hardly ever suffered before; and in this phase of bodily pain, Satan seemed to think:

"I wonder, now, if this will not be a good time to offer some suggestions to that pious chap. I have tried him with almost every thing, and he has snubbed me and misused me so much I should like to humiliate him a little."

I didn't think at the time that it was Satan; but afterward, as I pondered over it, I felt sure enough. Now, you may be a little curious, dear reader, to know how Satan could torment a body while sick and suffering. Well, Satan did come to me in a new phase. He came to me with an experience I had never had before. I suppose most of you know that my disposition is naturally hopeful. When even a small boy I was noted for being happy, cheerful, and contented most of the time. It didn't require companions and playmates or playthings to make me happy, either. The things of interest to be found in our dooryard, or, in the winter time, even indoors, were enough to furnish me with a vast fund of enjoyment. In fact, life, under all circumstances, has been a rare gift. I love to live. People have sometimes asked the question, "Does it pay?" I have always said, "To be sure, it pays, a hundred times over." When I have heard people talk about death being welcome, it has always seemed strange to me. This life may be painful, it may be

unpleasant; we may have many great trials; but I have always felt, that life is to be preferred under any conditions, to non-existence. I think I have said, sometimes, while discussing this matter, that I would unhesitatingly take the penitentiary for life, even if while there I should be deprived of hands and feet, sight, hearing, and, in short, every thing else it is possible to take away and still leave existence. My wife used to suggest killing a lame chicken, to "put it out of its misery;" but I always replied, "Why, my dear wife, how do you know that it is out of its misery when it is killed?" She always insisted, however, that everybody knows that a dead chicken does not suffer; but the latter has never been really clear to me. The chicken had tasted the pleasures of existence; and I was never satisfied that it would be happier dead than alive, even with a painful leg.

Perhaps, dear friends, you think there is no point here, and that this is aside from our text and from the letter from our friend. The point is this: For the first time in my life—at least, so far as I can remember—Satan suggested slipping off this rickety, pain-racked frame, and with it this sin-stained life of trial and suffering. Now, do not be in haste to jump at the conclusion that I permitted the terrible thought of suicide to once enter my mind. I did not, any more than so far as I am going to tell you. When Satan whispered that this life is but a series of trials and hardships any way, the old thought about the dead chicken came into my mind, and I began to feel like assenting to my wife's philosophy. Since becoming a Christian I have not dreaded death, because with it has come the thought that it would come when the Savior called; and I am sure it will be a glad moment for me when I can feel absolutely certain that he calls me anywhere—whether to *life* or to *death*. But that night a feeling came that I was getting old, and that it would be rather a relief to give up care and worry and pain, and take rest. Satan did not say any thing about what *sort* of rest it was to be; but to my feverish brain that night the idea seemed inviting. Then my mind recurred to the boy I found with his neck across the railroad track; and I thought of his philosophy, that in this way he could keep his promise to his mother, never to drink any thing more, and it seemed quite reasonable. Then I remembered those I had known, others I had heard of, who decided they would not stand suffering and torture any longer, and accordingly took upon themselves the terrible responsibility of ending life. Dear reader, have you ever had any experience of the rapidity and speed with which Satan can push ahead whenever he succeeds in getting a listener? Some of you may ask, "Why, brother Root, where was that little prayer of yours, that has all along these years rung out involuntarily—"Lord, help"? Well, it did ring out; may be there were only a few *brief minutes* before it sounded; but in those few brief moments I was made to feel that dangers awaited my frail bark of life that I had never dreamed of before. I was made to feel that new and un-

heard-of temptations and trials were probably yet in store for me. Right close after the prayer uttered, "Lord, help!" came Scripture texts, many of them, to comfort me. It seemed as if ministering angels were near—as if they had been all the time waiting with bated breath until bidden to approach and offer comfort; and one of the brightest and most precious of these texts was the one at the head of this paper—"Ye are not your own, ye are bought with a price." May God be praised for the consciousness that this is really so.

We are in the habit of thinking that we can do what we please with that which is our own. If you want to tear your own house down, you can do so; but you can not tear down your neighbor's house. You can, under certain restrictions, destroy property, if you choose; but you can not destroy your neighbor's property. Well, my friends, is it not true, that a great part of the world seem to be laboring under the delusion that they can do any thing they choose with these bodies—these temples of the Holy Ghost? But, hold on a minute, dear brother. The text says, "Ye are not your own, ye are bought with a price." You may say this text is for the benefit of Christians; that those who have no faith in God or the Bible, and who see things differently, may decide that they can do what they please with their own bodies; but, my friend, I believe that good common sense will decide here as elsewhere, that the Bible teachings are true, whether you have faith in God and the Bible or not. No one, since the world began, has ever had the right for a single moment to put himself out of existence. God gave life, and it is God alone who has the right to take it away. Probably none of us have any comprehension of the depths of suffering that a human being may be called upon to bear; but whatever comes, there is no question but that it is our duty to bear it. Of course, we are privileged to do every thing in the power of science or medicine to alleviate this pain; but when we fail we must bear it, and try to bear it patiently.

You know how strongly I have taught faith in prayer, all along these years. You know how earnestly I have enjoined every suffering son of Adam to go to the Savior when in trouble. Now, then: When we are suffering excruciating pain from sickness, toothache, earache, rheumatism, neuralgia, or all these things, does God hear, and does he care? To be sure, he does both. He may not think it best, however, to spare us these trials. I have been trying to tell you of a way in which he has not spared my poor self. I have not suffered very much bodily pain, it is true; but I have been pestered and tormented by the Prince of darkness more or less ever since I started out to be a Christian.

I have many times received much comfort in reading the experiences of the veteran Paul. You remember that thorn in the flesh. Paul wanted it taken away, but God decided differently. He told Paul, however, that his grace was sufficient, and it seems as if he had told me this many times. Well, during the night in question my suffering

was at a time—that is, so it seemed to my poor weak self—almost more than I could bear. I think it quite probable, however, that it did not compare with much that my kind and sympathizing wife has been called upon to suffer in many ways. Be that as it may, it was to *me* about all I could stand; and when these texts came thronging to my memory I begged piteously that God would have compassion on his poor weak child, and give him a respite, if consistent with his holy will. Now please, dear friends, believe that I am trying to give you plain and simple facts, without exaggeration or coloring, when I am telling you the experiences of this brief hour. I remember this vividly—the answer to my prayer came. I believe, almost instantly. The phantoms of my feverish brain seemed to vanish. I was *comparatively* free from pain, I was myself once more, and happy—yes, very happy, after the pain and the conflict. I stopped counting the tickings of the clock, and the hours as they struck, and slept peacefully, for I was at peace with my Maker.

You may notice in the above, that there is an intimation that I was out of my head a part of the time, as a result of the fever. Suppose a person should commit suicide under similar circumstances, when he did not know what he was doing, and do not such things often occur? My friend, it is my opinion, after what I have heard and read, and the experiences I have been through, that Satan is more or less in league with what we call insanity. I don't want to judge harshly, and I don't want to be uncharitable; but I do feel satisfied of this: That no insanity will ever be the cause of *my* committing any such terrible crime.

One of Satan's suggestions at the time I have been mentioning, was like this: "Suppose you were doomed to suffer thus, not only one night, but weeks, months, or years. You know many people do suffer in this way, and good Christian people too; would you bear it without a murmur?" Now, dear friends, I did not answer back that I would not bear it; but the pain and the delirium goaded me so that I felt very much inclined to say mentally, that I would not bear such pain, or worse pain, months or years, for anybody or any thing. I don't think I formed any idea in my mind just what I would do to get rid of bearing it, but there was a stubbornness and obstinacy in my heart that ought not to be in the heart of a Christian—no, not even when he is sick. Job's wife suggested to him that he should curse God and die. Job, however, was man enough to tell her she spoke as one of the foolish women. "Have we received good at the hand of God, and shall we not receive evil?" And the Bible says, that in all this Job did not sin with his lips. Perhaps he sinned inwardly, something as I did; but I believe, my friends, a human being under torture does pretty well when he keeps perfect command and control of the words that pass his lips. Satan commenced again: "You are partly crazy now. Is it not quite probable that you might be so delirious with fever as not to be aware of what you are doing? In that case, even God

himself could have nothing laid up against you.

This kind of logic sounds foolish in the clear light of day; but to my tortured and feverish imagination that night there seemed to be a sort of taking suggestion in such philosophy. I think I have now confessed the entire extent of how far I listened to these suggestions, and I am going to try to make his suggestions profitable by turning his words against him. I suppose you have found it to be true, that your dreams at night partake largely of the events and of your thoughts of the day. If you permit evil thoughts to find a lodging-place in your heart, evil dreams will follow. Well, I feel quite sure that insanity is something in the same line. We all know that insanity is often caused outright by sinfulness. Giving way to temper itself may make a man insane. Then many of us, at least, are partly if not wholly to blame for becoming insane. Furthermore, we are partly or wholly to blame for our conduct, or for things that happen while we are insane. If the truth could be known, I feel satisfied that a large part of the suicides that occur under the influence of insanity are the consequence of sin in some form before the insanity comes.

Perfect obedience and perfect allegiance to God and his laws are certainly a great safeguard against these evils. One whose whole attitude of thought and action is, "Not my will, but thine, be done," is not likely to be insane; and one whose whole life is thoroughly imbued with the thought of our text, it seems to me, would be hardly likely to commit suicide, even if he were out of his head through the effects of fever or other sickness. I have before mentioned facts that indicate that thoughts of self-murder grow little by little in the human heart, and I have been wondering whether there is any thing in my life during the past few years that had been encouraging a place for such thoughts in my own heart. I have all my life been nervous, impatient, and full of anxiety. When property accumulated on my hands I discovered that this must not be, or I should break down under it. With God's help I have been climbing above these human weaknesses. Going to sleep before our warehouse had stopped burning, was an illustration. Well, now, there is such a thing as slipping over into wrong, even in this direction. I do not mean in the way of trusting God, but in the way of indifference. Suppose some of the boys should run in and announce, "Mr. Root, your horses have run away, and they are smashing every thing to pieces." Now, it would be out of place to jump up and run and induce the men all over the establishment to stop their work, and run and make a great ado, when they could not do a particle of good. In view of this it might be well for me to tell the boy to go back to his work, and that the men in charge of the team would take care of the horses. Should I, however, omit to go very soon and look after things, I should be sinning by indifference where I had no right to be indifferent. I do not know but that I have been in danger of going too far in saying, when people are sick, "Just let them

alone and they will get well as quick, or quicker, than if you fuss with doctors and drugs and herbs."

Just a word in regard to my severe cold. The next morning I was a good deal sadder, if not very much wiser. Toward noon I got around to look after things, with a good warm undershirt and my overcoat and fur cap on. I felt pretty sick until I began to perspire freely out in the sun, then I began to feel tolerably like myself. For two days I perspired until all the clothing next to my body was dripping wet. The disease was broken. I did not have a cough, nor even a cold in my head, nor on my lungs. I followed Terry's plan, but I did not lie in bed. In the evening it was very necessary that I should be present at a meeting of the school-board. I went bundled up; but in spite of my heavy winter clothing, toward the close of our deliberations I began to get chilly. My son-in-law, fearing I might suffer by being out so late, had Meg and the buggy at the foot of the stairs; and just as soon as I came out he whirled me rapidly homeward. When I got there, however, the chill had come back. I ran into the house, and called my wife to pull down the big blankets again, and she covered me up, overcoat, fur cap, and all. But the gasoline-stove had to be lighted, and the soapstone made hot again before I could check the chill. Now, I didn't take any medicine whatever — not even catnip tea; and yet I doubt if many recover with the aid of a physician any quicker than I did. A few years ago, hot whisky-sling would have been the thing; but I am glad that we have proof that heavy clothing and hot soapstones are better and cheaper than whisky-slings.

Among the many letters in regard to temptation comes one with a clipping from the *Parish Visitor*, New York. The title of the article is,

TEMPTATION A MEANS OF GRACE.

If you are strongly tempted, give thanks for it. It is no occasion for mourning or discouragement, but the reverse. It is a sign that you are in the "high places" of Christian experience, where "wicked spirits" (Eph. 6:12) are peculiarly numerous and strong. It is a sure sign that the Spirit of God is in you, for "the flesh lusteth against the Spirit;" it is the presence of the Spirit there that calls forth the malice of Satan. It was when Jesus was "full of the Holy Ghost" that he was tempted of the devil.

The best, if not the only, way to triumph over a temptation, is to turn it into a means of grace. You are beset behind and before, without and within. You find your will itself, seemingly, if not actually, consenting to the snare presented. What then? Christ is by your side; yes, nearer still; he is within you. There is nothing in him that consents to this snare. Take refuge there. Let the force of the temptation drive you instantly into the safe shelter of his purity and power, and so become a mighty means of grace to advance you to a position in Christ which, but for it, you might never reach. Nothing will so foil the tempter and his wiles. Nothing will so strengthen your Christian character and standing.

We are reminded here of the characteristic and suggestive remark of a very quaint but godly man, who had an original way of putting things, peculiar to himself, and who, moreover, was always keenly alive to the designs of Satan, and singularly successful in defeating them. He was asked, "What do you do when the devil tempts you so that you feel dry and cold, and without any spirituality?" "Take him to a prayer-meeting," was the prompt reply; "he don't trouble me long when he finds where he has to go."

The most successful general is the one who knows best how to make use of the enemy's stratagems to his own advantage. So must we turn the weapons of our spiritual enemy against himself if we would come off victorious in the conflict.

The concluding thought in the above has been wonderfully true in my experience. I am sure it will never be a safe thing for me to give up going to prayer-meeting. When I have battled alone unsuccessfully with evil, standing up before Christian friends and neighbors, telling them of my trials, and asking them for their prayers, has always given me a new start and a new portion of God's grace; and above all, dear brother, whether you are sick or whether you are well, and under whatever condition or circumstance you may be, hold fast to the thought, "Ye are not your own, ye are bought with a price."

Sin of my soul! thou Savior dear,
It is not night if thou be near;
Oh, may no earth-born cloud arise
To hide thee from thy servant's eyes!

TOBACCO COLUMN.

THE EFFECT OF TOBACCO ON OFFSPRING.

I HAVE not watched Mr. Root's Tobacco Column very closely, and, may be from selfish motives, for it has never been of any particular interest to me, never having made a habit of smoking. I am, however, surprised that Mr. Root did not know that tobacco killed others than the smokers, although perhaps indirectly. Mr. Terry says some constitutions can bear the poison. Permit me to state, I think not. Let us take those constitutions which appear to bear the poison, and our best physicians say of them, the effects of the poison may not be very marked in the smoker, but the effects are greater in the offspring, and the nervous system is injured in the children of such a man; and at such times, when others would not succumb to a disease, such constitutions are unable to withstand the crisis.

For children of God to use tobacco is very inconsistent. They smoke, and what are they doing, even were it not physically injurious? Are they walking according to the Spirit of God, as we are directed to do, or according to the flesh, as we are warned not to do? Certainly the latter. I can never see a man smoke, especially a young man, without thinking he is gratifying his flesh, and building it up and giving himself trouble in other respects, without one redeeming feature. I will lay aside the extravagance and selfishness of such, and dwell only upon the fostering of what is fleshly, and therefore the smothering of the Spirit of God in his holy temple, who dwells in us, and whose temple we should seek not to defile. For the unsaved, he which has not eternal life, the injury which he may do to those unborn, and he who has their welfare at heart, and is not utterly selfish, will surely give the benefit of a doubt, even should a doubt exist in his mind as to the injury caused by the use of tobacco to such; but such a doubt will not exist in the mind of one unprejudiced, and who has read the opinions of authorities. R. F. HOLTERMAN.

Brantford, Canada.

I have been telling my neighbors that you proposed making any person a present of a smoker

who would quit the use of tobacco. Some say they will quit chewing, but will have to smoke, but I tell them that won't do. David E. Derrick, of Opossum, Tenn., says he has been smoking the weed for some time, and has quit entirely; and he says if you will send him a smoker, and he ever uses the weed again, he will pay for the smoker; and I will also pay you for one if he uses any more tobacco. I do not use it, and never did. I am trying to get all my neighbors to quit the habit. M. M. DERRICK.

Stony Point, Tenn.

Accept our thanks for the kindly interest you take in this department, and for the efforts you are putting forth to make larger the number of men clean from the filthy habit.

I have quit the use of tobacco, and I promise to pay for the smoker if I ever use tobacco again, which I am sure I never shall. C. WITTER.

Salem, Ind., May 12, 1887.

I have resolved to quit using tobacco for a Clark smoker. If I commence again, I will pay your price. P. A. COOK.

Cherokee, Tex., May 2, 1887.

I have quit the use of tobacco, so please send me a smoker. If I commence the use of tobacco again I will pay you for the smoker.

J. F. WEATHERLY.

Woods, Tillamook, Co., Ore., April 26, 1887.

OUR OWN APIARY.

CONDUCTED BY ERNEST R. ROOT.

"WHAT HAS THE HARVEST BEEN?"

WHITE clover in this locality was almost a total failure; in fact, during the time it was in bloom we had to feed some colonies or incur the risk of their swarming out or starving altogether. As it has sometimes happened in other years, the conditions of weather, which are entirely unfavorable for the secretion of nectar from clover, are eminently favorable for a heavy flow from basswood. So it was this year. The yield from basswood has been exceptionally good—quite counterbalancing the entire lack from clover. Neighbor Shane, located some six or seven miles from us, reports that he has had one of the best yields of basswood honey he has had for years.

THE T SUPER, AND THE SLATTED HONEY-BOARD.

Our experiments this season have fully sustained what Dr. Miller and others have said in favor of the T super, and I am not sorry that we followed the doctor's instructions as to its proper construction as closely as we did. Indeed, I can not help regretting that we did not take his word for it one step further; i. e., make the super 12½ in. wide instead of 13½, as we did; but I shall have occasion to speak of this further on.

Judging from our experiments with the T super this season, I can scarcely conceive how, used in connection with the slatted honey-board, it can give any more satisfactory results when properly manipulated.

To use it without the honey-board would be simply intolerable, and my experiments with the plain zinc honey-boards, with which there is no provision for a bee-space, convinces me that this latter is about as bad as no honey-board.* To get clean sections with the T super, we must have a honey-board with some sort of provision for bee-spaces above and below the sections. If Mr. Heddon first called the attention of bee-keepers to the advantages of a slatted honey-board with a bee-space provided for above and below, he deserves a vote of thanks, so there!

GETTING BEES INTO SECTIONS, AND WHAT SOMETIMES PREVENTS THEIR GOING UP.

Here at the Home of the Honey-Bees the locality is greatly overstocked, there being something over 300 good colonies in this vicinity. Each colony can not, as a consequence, secure more than its proportional amount of nectar, and this amount is not large. When in most localities the bees would pass up readily and without trouble into the sections, in our locality we must do a considerable amount of coaxing; and, as a means to this end, try those conditions which are the most favorable for getting the bees up into the sections.

On some colonies we placed T supers without contracting the brood-nest; but never a bee thought it his duty to make even an inspection tour above.

In other colonies the brood-nest was contracted from two to six brood-frames, depending upon the strength of the colonies. Where contraction was carried to extremes, the bees did not fail to go above and commence work. Colonies whose brood-chambers were reduced to not less than six frames sometimes did, but as a general rule did not go above. Those that did make some sort of demonstration above had sections on top with full sheets of foundation, and with *no tin separators*. In every case the presence of full sheets of foundation, or the absence of *tin separators*, made a very appreciable difference in the readiness with which the bees entered the sections. I had long known that full sheets were considered a material advantage. I knew, also, that Dr. Miller preferred *wood separators*, stating that the latter seemed to be preferred by the bees; but I did not know that bees showed their aversion to the metal so *plainly*. During a heavy flow of honey in a locality not overstocked, it is possible they would indicate no decided preference in favor of either wood or tin separators. How is this, friends? Let us hear from you.

T-SUPER COVERS NECESSARY.

When we put on the supers at the Hyde apiary, at the beginning of the honey-flow, we had forgotten to bring along T-super covers. We did not think them so very important then, and so matters went for a week or ten days. At last we went down, taking with us the T-super covers and more supers. On our arrival, Mrs. Hyde informed us that the bees had not gone into the sections yet. I was a little surprised, but did not then suspect the cause. At any rate, the T-su-

per covers were placed on all the supers. At our next visit, shortly after, Mrs. H. told us that the bees quite promptly entered the sections after the super covers were placed on. The trouble was, with the whole capacity of the upper story of the hive, the bees could not generate sufficient heat for wax-working in the sections, and for the proper evaporation of honey. Just so soon, however, as the super was closed with the cover, the bees improved the opportunity.

COULD THE T-SUPER BE ADAPTED TO AN EIGHT OR TEN FRAME HIVE?

When a ten-frame hive is contracted to six frames, and then covered with a super $13\frac{1}{2}$ in. wide (equal to the whole width of the hive) the bees are very much indisposed to have any thing to do with the two outside rows of sections—those rows which project over and away from the brood. It is a mistake to carry contraction too far, and yet with a T super wide enough to cover ten L. frames, contraction can not be carried to six frames without removing the brood entirely away from the two outside rows of sections. If our supers were made $12\frac{1}{2}$ in. wide, contraction could be extended to 6 frames, it seems to me, to far better advantage. How is this, friends?

THE SOLAR WAX-EXTRACTOR.

When honey from basswood began to come in briskly, as a natural consequence burrs commenced to crowd up on top of the frames. We have heretofore taken these bits of comb and honey after they have been scraped off, ate what we could, and the rest were dumped into an old pan in the honey-house, to lie around and bait robbers. One day while I was walking through the apiary I noticed the boys wadding up the wax into a ball, and stuffing it down at one side of the hive. The bees, after extracting the adhering honey, would fasten the balls securely to the side of the hive, and it would be quite difficult to remove them afterward. I told the boys to bring out the solar wax-extractor and set it in position, which they did. Thereafter the chunks of wax and honey were dumped into the extractor. In a few minutes the comb would melt and run down through the perforated metal. In the course of ten days we found that we had secured, just from these little pieces of wax, 13 lbs. of nice yellow wax—as nice as any one ever saw, and nearly 5 lbs. of basswood honey. The color of the latter was a little dark, but its flavor, it seemed to me, was quite as good as that which we take in the ordinary way with the honey-extractor.

The solar wax-extractor, as you are aware, is automatic. It can be located in the sun, right where you want to work, and you do not have to run away down to the honey-house to put away a chunk of honey that your poor stomach has long ago refused to take care of. In three or four days your wax and honey accumulations will probably have pretty nearly filled the pan. At night, after the sun has gone down, the wax will harden into a nice yellow cake, and the honey can be drawn off at the honey-gate near the lower part of the pan. You thus keep your apiary neat and tidy; and not

* I should have said here, that if the plain zinc boards are bee-spaced on both sides with the quarter-inch strips they will answer perfectly well.

only that, you have your refuse put immediately into marketable shape. Let us see: In ten days, just from little bits of scraps we obtained 13 lbs. of an extra quality of wax. At the lowest figures, or 22 cents per pound, this would amount to \$2.86; 5 lbs. of basswood honey at, say, a low calculation, 7 cts., 35 cts. Total, \$3.21.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER,
MEDINA, OHIO.

MEDINA, JULY 15, 1887.

It is the Lord: let him do what seemeth him good. I. SAM. 3. 18.
Shall not the Judge of all the earth do right?—GEN. 18.25.

THOMAS WM. COWAN.

The following card comes to hand from Professor Cook:

MR. EDITOR:—A letter from Mr. Cowan, editor of the B. E. J., tells me that he sailed on the 9th for America. Mr. Cowan is a gentleman of culture, a man of generous heart and purpose, and perhaps the most thoroughly informed bee-keeper in England. Let us all show him that we appreciate real worth, by giving him a most hospitable welcome and entertainment while he is with us. I wish we could keep him till our North-American Association meets in November, but I fear we can not.

Agricultural College, Mich., July 11, 1887.

All right, friend Cook. We heartily second all you say. We hereby extend to Mr. Cowan a hearty invitation to call upon his friends in Medina. If he can make it convenient to stop off with us for a while we will give him a hearty welcome.

A WELL-BALANCED JOURNAL.

THAT is what we are trying to have GLEANINGS, but there seems to be a constant tendency toward giving undue prominence to certain matters; but if we consider all the different subjects within our scope, at least to some extent, we are obliged to be continually repressing as well as encouraging. Just at present the number of kinds words for the Home Papers, accompanied by Scripture texts, and strong earnest words from good men and women, would seem to all demand a place, but space forbids. Sometimes, it is true, I take the liberty of adding a page or two to give you something I deem valuable in regard to some of my pet hobbies and industries. But this costs money, and I don't feel as if I ought to do it unless I can feel pretty certain that our readers will be benefited enough to warrant the expenditure.

THOMAS HORN.

I HOPE, dear friends, we are getting near the last chapter. Now, while I really can not see wherein I have been at fault in the matter, nor can I see clearly how I shall be able to guard against similar impositions in the future, I have decided to make good the amounts that our subscribers lost by sending to Mr. Horn. Tell me briefly how much money you sent him, for which you received nothing, and we will place the amount to your credit, to be taken

in bees and queens at our regular prices. As a matter of course, no bees or queens will be taken from any apiary where foul brood does now exist or has existed for six months or more. We can not agree to pay express charges, however, as did Mr. Horn; and I hereby protest against any other advertiser making any such or similar offer. No one can pay express charges to any point, when it is often likely to be much more than the amount of money received. We have a record of the names and of the amounts, in a book; but the whole correspondence was sent to Mr. Horn, to enable him to fix the amounts of notes he was to send out. Nobody has ever yet received a note from him, so far as we can learn, and it is on this account that I propose to settle as above. If Mr. Horn can tell such willful falsehoods now, when there seems to be no object in it, he probably was a swindler in the outset.

SPECIAL NOTICES.

WANTED—BACK NUMBERS OF GLEANINGS.

At the present time we are making up and binding a few back volumes of GLEANINGS, from the time it started up to the present time. We find that we lack the following: March and November, 1881; Jan. 15, Feb. 15, March 1 and 15, and Dec. 1, of 1882. Any of our readers who may have a copy of the above numbers to spare, we would gladly pay them 10 cts. for each copy.

REDUCTION IN THE PRICE OF PARAFFINE.

THERE are many uses to which this article may be applied at this time of year, and later, such as waxing honey barrels and kegs, and waxing bee-feeders for feeding up your bees in the fall, etc. We are pleased to announce the following low prices: 15 cts. per single pound. In cakes of about 12 lbs., 12½ cts. per lb. In original cases of about 250 lbs., 10 cts. per pound.

A CARLOAD OF BASKETS.

As a light and cheap package for handling and shipping small wares, nothing compares with what is commonly called the "market basket." We have for years, in our counter store, given away a basket when a customer bought enough goods to fill it; and merchants are more and more finding out that it is cheaper for them, and a great convenience to their customers, to practice the same thing. Ever since we have been making the Clark smoker we have been shipping them by express in baskets, 5 in a basket, because we could not begin to make a crate to hold 5 smokers, for twice what a basket costs, and then the crate would weigh as much, or more, than the smokers. I believe there are many uses to which we might put these market baskets if we get them cheap enough, and always have them handy by. We use so many that we buy them by the carload, and thus get bottom prices. One great objection to shipping baskets is the enormous freight charges demanded by the railroad companies. Baskets with handles on, and nested in the ordinary way, are charged at four times first-class freight; but the last carload we received a few days ago are so packed that they will go as double first-class freight, the same as bee-hives nailed up.

These baskets in question are put up, three sizes in a nest, as follows: Three ¼-bushel, four ½-bushel, and four ¾-bushel baskets, making in all eleven baskets in each nest. All include handles, but they are loose, and have to be tacked in after you get them. They are the celebrated "Diamond" basket, and better than any other we have ever had. As they come to us thus nested, and as they ship at a lower rate of freight than in any other shape, we have decided to sell them by the nest, at the following prices: 35 cts. per nest of 11 baskets; \$3.25 for 10 nests; \$30.00 per 100 nests. At this very nominal price, your baskets cost you about 3 cts. each. We also include tacks to nail the handles in with, at these prices. Each nest weighs 8 lbs., and you can tell what the size is by turning a half-bushel basket upside down on top of another.

DADANT'S FOUNDATION

is asserted by hundreds of practical and disinterested bee-keepers to be the cleanest, brightest, quickest accepted by bees, least apt to sag, most regular in color, evenest, and neatest, of any that is made.

It is kept for sale by Messrs. T. G. Newman & Son, Chicago, Ill.; C. F. Muth, Cincinnati, O.; Jas. Heddon, Dowagiac, Mich.; Dougherty & Wiley, Indianapolis, Ind.; B. J. Miller & Co., Nappanee, Ind.; C. H. Green, Waukesha, Wis.; Smith & Goodell, Rock Falls, Ill.; Ezra Baer, Dixon, Lee Co., Ill.; E. S. Armstrong, Jerseyville, Illinois; Arthur Todd, 2122 North Front Street, Phil'a, Pa.; E. Kretzmer, Coburg, Iowa; P. L. Viallon, Bayou Goula, La.; M. J. Dickason, Hiawatha, Kansas; J. W. Porter, Charlottesville, Albemarle Co., Va.; E. R. Newcomb, Pleasant Valley, Dutchess Co., N. Y.; D. A. Fuller, Cherry Valley, Ill.; J. B. Mason & Sons, Mechanic Falls, Maine; G. L. Tinker, New Philadelphia, O.; Jos. Nysewander, Des Moines, Ia.; Aspinwall & Treadwell, Barrytown, N. Y.; Barton, Forsgard & Barnes, Waco, McLennan Co., Texas; W. E. Clark, Oriskany, N. Y.; G. B. Lewis & Co., Watertown, Wis.; E. P. Smith, Smyrna, N. Y.; J. Mattoon, and W. J. Stratton, Atwater, O.; Oliver Foster, Mt. Vernon, Iowa, and numerous other dealers.

Write for samples free, and price list of supplies, accompanied with 150 Complimentary and unsolicited testimonials, from as many bee-keepers, in 1883. We guarantee every inch of our foundation equal to sample in every respect.

KIND WORDS FROM OUR CUSTOMERS.

The goods we ordered from you this spring pleased us very much; the platform scales are cheap. I can weigh my bees, honey, or family on them.
Youngstown, Ohio. W. A. MITCHELL.

I write this to let you know that I am well pleased with the A B C book. I have learned more about the honey-bee from that book than I could have learned in any other way for a long time.
Stony Point, Tenn. M. M. DERRICK.

THAT IMPORTED QUEEN.

The imported queen I got last season did well, and is doing well yet; her bees are very dark, all well marked. Quiet, and as good as any in the apiary to gather honey, and she has laid more eggs by half than any other queen I have.

Wyoming, Ont., June 21, 1887. A. E. HARVEY.

PROMPTNESS AND GOOD WORK.

The extractor ordered of you was received in good order, and to say that I am well pleased would be putting it lightly. It is more than I expected for the amount of money it cost. My order went out the 18th of June, and on the 23d my extractor was at Morristown—just five days'—quick work, you see.
L. DYER.

Morristown, Ind., June 27, 1887.

OUR 50-CENT HAND-SAW.

The package containing the 50-cent hand-saw, etc., was received yesterday, only six days since I sent the order. I was not expecting it so soon. Accept thanks; that saw is so nice I keep congratulating myself on having sense enough to send for it. Your A B C told me what to do with the drone-layers in two of my Italian colonies, and one of them has a nice yellow queen now. You see, I have learned only just a little.
MARY L. BECK.

Bethel, O., May 20, 1887.

BEES ARRIVED IN FINE CONDITION.

I have waited a few days after the arrival of the bees, to see how they behaved. They reached this place on the noon of June 3d, filled with life, and seemingly happy to make a visit to New Hampshire. I gave them a new hive, and every bee entered the new residence. The next morning they were placed in the apiary, and from that time to this have represented themselves as perfectly contented. On examination we found the queen, and trust that both queen and bees are in the best condition. The metal corners are a success, and with these one can make a very nice and substantial frame. We have no trouble in attaching them to the frames, as we followed the directions sent with the package.
H. C. BLINN.

Shaker Village, N. H., June 8, 1887.

Hurrah for the Fair!

Now is the time to work up your home market, and there is no better place than at your local fair. Don't let the chance of advertising your business slip by. A fine exhibit and a judicious distribution of

THE BEAUTIFUL CHROMO CARDS

Will set the business booming. A leaflet or circular will soon be thrown away or lost; but this card will be taken home and studied by a score of persons, making your name a household word for miles around. Our card is especially gotten up for bee-keepers, brilliantly printed in eight colors, and is both instructive and amusing. Send for free samples, and get out of that old-fogy rut.

ITALIAN QUEENS.

I am also trying to breed a superior strain of Italian queens, a cross between the old Quinby stock and Doolittle's, bred in an apiary three miles from other bees. I can almost guarantee their purity. They will not disappoint you.

Address J. H. MARTIN,
151fd Wash. Co. Hartford, N. Y.

\$2. FULL SWARMS. \$2.

Fine Italians. Hayhurst's stock, before Aug. 20. Full swarm with queen, no combs, \$2.00. Same with 8 brood-combs, \$3.00. Same with 8 combs in S. hive, \$4.00. C. B. THWING, Hamilton, Mo.

Highest Quality Italian Queens

at Lowest Prices. Untested, 75 cts. Selected tested, reared in 1886, \$1.50; 2-fr. nucleus with untested queen, \$2.00; with tested queen, \$2.50. Bees, 50 cts. per lb. FRANK M. BALDWIN, Marion, Ind. 14-15fd

Beautiful Italian Queens.

J. F. Wood wishes to inform the readers of GLEANINGS that he is now filling all orders promptly for those golden queens, that have given universal satisfaction to all his customers the past two seasons, at 75 cts. each. I use no lamp nursery. Do not fail to send for my 1887 circular. Address 14-15 16d

JAMES F. WOOD, North Prescott, Mass.

BEES, 50 Cts. Per Lb.; 5 lbs., \$2.00; 10 lbs. and a tested Italian queen, for \$4.00.
15d C. G. FENN, Washington, Conn.

Italian Bees and Queens.

Full colonies, \$6.00. Bees, per lb., 75 cts. Frame of brood and bees, 75 cts. Tested queen, \$1.25. Untested, 75 cts. Mismatched, 35 cts. Queens reared from imported mother. MISS A. M. TAYLOR, 141fdb Box 77. Mulberry Grove, Bond Co., Ill.

HEADQUARTERS IN ILLINOIS

For the Manufacture and Sale of

BEE-KEEPERS' SUPPLIES

8 and 10 frame Simplicity hives furnished at a great reduction in price. Nice sections and foundation specialties. A full line of supplies always on hand. Write for my new price list
12-15d F. M. ATWOOD, Rileyville, Ill.

Tested Italian Queens

REDUCED TO \$1.00 EACH.

Untested, 75 cents each. Bred either from imported Bellinzona (dark strain) or albino (light strain), as preferred. Orders filled promptly, and satisfaction guaranteed. Circular free. 91fdb Chas. D. Duvall, Spencerville, Mont. Co., Md.

HONEY COLUMN.

CITY MARKETS.

ST. LOUIS.—*Honey*.—We quote choice comb 8@10 cts.; latter is for choice white clover in good condition. Strained in bbls., 3½@4 cts. Extra fancy, of bright color and in No. 1 packages, ¼ cent advance on above. Extracted in bbls., 4¾@4½ cts.; in cans, 5 cts. Market dull and receipts increasing.

Beeswax steady at 21 cts. for prime.

July 21. D. G. TUTT & Co.,
206 N. Commercial St., St. Louis, Mo.

MILWAUKEE.—*Honey*.—The old crop of honey is very nearly out of sight in this market, and many are now ready for the new crop. We quote as follows:

Choice comb, 1-lb. sections, new;	14@15
" " " " old,	12@12½
" " 2-lb. " not salable,	10@11
Extracted, white, in kegs and bbls.;	7@7½
" " " " Tin, small,	7½@8
" " " " dark, in kegs and bbls.,	6@6½
" " " " Tin, small,	6½

Beeswax, 25. A. V. BISHOP,
July 21. Milwaukee, Wis.

PHILADELPHIA.—*Honey*.—Honey and wax very quiet. Quotable nominally as last reported.

July 22. PANCOAST & GRIFFITHS,
Philadelphia, Pa.

BOSTON.—*Honey*.—1-lb. sections, 13@15
2-lb. sections, 11@13
Extracted, 5@7

Beeswax, 26. BLAKE & RIPLEY,
July 22. 57 Chatham St., Boston, Mass.

NEW YORK.—*Honey*.—The honey outlook in New York and Pennsylvania is very good.

Beeswax, fair demand; selling at 22@23c.

July 22. THURBER, WHYLAND & Co.,
New York City.

ST. LOUIS.—*Honey*.—There is no change to report on old honey or wax since our last report. There is some light demand for choice new white-clover honey in comb, 1-lb. sections, at 12½; good fair stock, 12c.

W. B. WESTCOTT & Co.,
July 22. 108 and 110 Market St., St. Louis, Mo.

DETROIT.—*Honey*.—Very little new comb honey in market. Demand better and prices advancing. We made a sale to-day at 14c.

Beeswax, 23c. M. H. HUNT,
July 22. Bell Branch, Mich.

CHICAGO.—*Honey*.—Old crop of honey is exhausted, some few consignments of the new crop coming forward, and selling at 16c for choice one-pound combs. Not any two-pound sections are at present here. Extracted honey, 5@7.

Beeswax, 22c; light offerings. R. A. BURNETT,
July 21. 161 So. Water St., Chicago, Ill.

CLEVELAND.—*Honey*.—There is no new honey coming forward, and we can not give definite prices. Considering the shortness of the crop, however, we think 15@16 for best white 1-lb. sections should be obtained.

A. C. KENDL,
July 26. 115 Ontario St., Cleveland, Ohio.

WANTED.—All the bee-men who see this adv't to send us one hundred pounds of 1-lb. and 2-lb. sections of white comb honey, as sample, by express, stating quantity, and price for same, cash, delivered in Kansas City, Mo.

CLEMONS, CLOON & Co.
Cor. 4th & Walnut Sts.

WANTED.—To purchase from one to five thousand pounds choice white-clover honey in one-pound sections. Crates to average about 25 lbs. each.

I. T. CARSON & Co.,
15-16d 325 West Main St., Louisville, Ky.

Bees for Sale in Florida,

In Langstroth hives, at \$3.00 to \$4.00 per colony.
J. L. Wolfenden, Evinston, Alach. Co., Fla.

BEEES

That Have Stood the Severe Northern Winters are the Hardest.

I have a limited number of Italian bees for sale at \$5.00 per swarm in shipping-case; also a few queens, tested, \$1.25; untested, 75 cts. Must be sold during August. Send at once.

WM. H. HUSE, Manchester, N. H.

W. Z. HUTCHINSON,

ROGERSVILLE, GENESEE CO., MICH.,

Has received many complimentary letters in regard to his little book,

"THE PRODUCTION OF COMB HONEY."

The following is a sample:

Friend Hutchinson.—Your little book was read with very great interest; and as I closed it I said to my wife, "I wish Mr. H. were here this evening. I think I could keep him busy awhile with questions." There is a great deal in your book which I know by experience to be correct; and if your whole plan is found to be so, and is generally adopted, it will certainly work a revolution in bee-keeping.

Yours Truly, E. M. HAYHURST.

Kansas City, Mo., April 10, 1887.

Price of book 25 cents. Stamps taken, either U. S. or Canadian.

Fine Italian Queens, reared from best selected, tested, imported mother, 75 cts. each, by *return mail*. 10tfdb

FOR SALE!

A good, improved 160-acre farm, with 20 acres choice timber. Also

82 COLONIES OF BEES

in good condition; must be sold before Sept. 1st.

HONEY - STAND

—FOR—

RETAILING EXTRACTED HONEY.

As the honey crop is in, and the time for fairs is approaching, you may be looking about for something neat and tasty for showing up your honey in nice shape. The above cut represents a nice stand for extracted honey, in different styles of packages. The ends are made of blackwalnut, and the shelves and back of basswood, stained dark color. We can furnish the above, nailed and lettered, complete, as shown, without the tin cans or tumblers, for \$1.00, or 10 for \$7.50. In the flat, 60 cts. each, or \$5.00 for 10.

A. I. ROOT, Medina, O.

Vol. XV.

AUG 1, 1887.

No. 15.

TERMS: \$1.00 PER ANNUM, IN ADVANCE;
2 Copies for \$1.90; 3 for \$2.75; 5 for \$4.00;
10 or more, 75 cts. each. Single num-
ber, 5 cts. Additions to clubs may be
made at club rates. Above are all to
be sent to ONE POSTOFFICE.

Established in 1873.

PUBLISHED SEMI-MONTHLY BY

A. I. ROOT, MEDINA, OHIO.

Clubs to different postoffices, NOT LESS
than 90 cts. each. Sent postpaid, in the
U. S. and Canadas. To all other coun-
tries of the Universal Postal Union, 18
cts. per year extra. To all countries
not of the U. P. U., 42 cts. per year extra.

PAINTING HIVES, ETC.

DOOLITTLE'S VIEWS ON THE SUBJECT.

ON page 496, current volume of GLEANINGS, the editor asks if painting the front of the hives in different colors makes any difference with the bees as to their ability to distinguish their own hive. Yes, I think it does; but the hive has not so much to do with it as does the alighting-board, or projecting part to the bottom-board. Several times I have been obliged to change bottom-boards to some old hives, the bottoms to which had been made of basswood; and when the new bright pine bottom-boards took the place of the old ones, the bees returning from the field would hover about for a long time before they dared to drop upon this (to them) strange object. This reluctance to enter the hive would last for two or three days, when finally they became used to it, and in two weeks a change back again to a dark weather-beaten board would cause the same reluctance to entering again. As my bottom-board projects ten inches in front of the hive, for an alighting-board it will be seen that the whole width would present quite a different appearance. Again, I now use one hive for two nuclei, with the entrances only about 16 inches apart, and facing the same direction, the hives being painted all alike; yet by the use of the elevated boards spoken of in the last paragraph of my article on page 496, I never lose a queen by her entering the wrong entrance. By changing this board I can cause the same hesitancy with the bees about entering their own home, spoken of above.

CHILLED BEES.

Page 498, July 1 GLEANINGS, has something to say

about chilled bees, saying, "Perhaps Doolittle may enlighten us further." Out of some five different experiments along the McFadden line to see how long I could keep half a teacupful of bees alive after being chilled, 4½ days was the latest point at which any could be brought to life again by warmth with moisture, and 3½ days by dry heat. Moist warm air seems to be more effective in restoring such bees than dry or stove heat. These bees were shaken on the snow, with a temperature a little above the freezing-point; and as soon as they ceased to move I picked them up and carried them to the cellar, of the same temperature in which bees winter well. From the cellar, a few were taken every half-day, and warmed, with the above result. All of them had empty stomachs, and I still have a desire to try bees gorged with honey, to see if that makes any difference. In two instances, after picking up half a teacupful of bees, and leaving them in a cup or pile, they came to life again; while if scattered about, none did. It would seem that this would be against the McFadden plan, if nothing else about it is. Prof. Boynton was sanguine that the thing would work, but he has gone out of bees, and I have lost track of him.

CAPPED QUEEN-CELLS AND FIRST SWARMS.

It would seem as if Prof. Cook must have read my article on swarming rather carelessly (page 510, July 1). I did not say that first swarms never leave without sealed queen-cells, as the professor will see if he carefully reads my article again. I said the *first swarm of the season*, by which I meant, if Prof. Cook has 20 colonies to cast swarms, the first of those 20 swarms will not issue without one or more capped queen-cells; and with me this rule holds

good, no matter what variety the bees are. After this first one, others often come with no preparation for swarming, as Prof. Cook tells of, as I conceded in my former article. Then again, friend Cook, Doolittle made no "assertion" regarding even the first swarm of the season. I said I had never known them to do otherwise, but did not say but they might. Candidly, friend C., did you ever know the very first swarm that issued in an apiary to do so before the queen-cells were sealed?

QUEEN-CELL PROTECTORS.

I wish to say a few words more regarding queen-cell protectors. Since writing last about them I sent for ten of friend Root's make, and I find them too flaring, or too large at the big end. The taper wants to be so slim that the protector strikes the sides of the cell before the point comes to the apex of the protector, keeping it back from $\frac{1}{8}$ to $\frac{1}{4}$ of an inch, while these last allow the point to stick through about that far, so the bees can tear the end off if they wish. When just right it is impossible for the bees to bite into the cell—at least, so it seems to me.

Now a word about using them. Instead of folding the ends of the wire cloth over the cell, as friend Root directs, put a wooden plug or a piece of corn-cob in after the cell, and fold the wire cloth over that, or, better still, clip off what of the wire runs above this stopper. In using, lift a comb from the hive; and in a place near the brood, mash with the finger a few cells down to the base of the comb; and in this indentation in the comb place the base of the protector, pressing it in by bearing against the side of the protector and stopper. This imbeds it in the comb so it will stay; and when it is lowered into the hive the combs come together as if nothing were there, after which it is impossible for it to fall out. This does not injure the combs any; for as soon as the protector is taken out, the bees raise the cells again. To avoid chilling the cells in cool weather, take to a warm room to fix in the protectors; and when ready to go to the hives, put the protectors around next to the body, in front, under the waistbands to the pants, the same as cartridges would be slipped in a belt. This keeps them in an upright position, snug and warm, and allows of stooping to open hives, etc. Embryo queens are easily chilled, and I mistrust this may account for some of the failures.

G. M. DOOLITTLE.

Borodino, N. Y., July 18, 1887.

Many thanks to you, friend D., for the result of your experiments in keeping chilled bees. I am astonished to know that you succeeded in keeping them as much as four days and a half; but I was prepared, after all, to hear that the period might be longer than we had formerly put it, for I have made a few bees come to life at different times, when it seemed to me as if they had been out of stores a good deal longer than 24 or 48 hours. Now, who will help us test this matter by chilling some bees when they are full of honey? Take some from a hive right in the height of the clover or basswood flow, for instance, and chill them in an ice-house, just so they won't move, and keep them there. Thanks, also, for the suggestion in regard to the queen-cell protector. This illustrates once more how small a matter will make all the difference between success and failure.

CELLAR VS. OUTDOOR WINTERING.

SOME EXCELLENT IDEAS FROM FRIEND HUTCHINSON IN REGARD TO THE MATTER.

IT is a pleasure indeed to discuss apicultural problems with such a man as O. O. Poppleton—one who can lay aside prejudices, and calmly and fairly try to find *truth*. I am glad to note with what unanimity most of the bee-journals and their contributors are dropping personalities—discussing *principles* instead of men.

It is true, that these matters under discussion between friend Poppleton and myself are foreign to the main topic of my little book; but they are important and seasonable.

In regard to caring for bees in the cellar, there may be a grain of truth in what Mr. Poppleton says. If a man wishes to leave his bees uncared for all winter, and go off to the land of flowers, it may be better to protect them thoroughly upon their summer stands. Most of our bee-keepers, however, stay at home winters, and to them this question of supervision is not a weighty one. Take my own case, for instance. My bees were kept in a cellar under the sitting-room, hence there was no expense for a fire on account of the bees, or else there was no expense for a fire to keep *ourselves* warm. I presume the majority of bee-keepers are situated in *exactly* this manner. And now about the supervision in regard to temperature. We ripped apart, for a short distance, two breadths of the carpet, bored a hole in the floor, and suspended a thermometer by means of a string attached to a cork that just filled the hole in the floor. A rug was kept over the slit in the carpet. Our little girls kept watch of the temperature. It seemed to afford them considerable pleasure to have each one guess what the "tempuchary" (as the youngest one called it) was, and then look and see who had guessed the nearest. The "tempuchary" varied from 40 to 48°; most of the time it was 45°. When we had extremely cold weather, accompanied by high winds, the mercury would sink to 46°. Upon several occasions I kept a lamp-stove burning all night in the hatchway, and burned, perhaps, between one and two gallons of oil. Had there been a double door to the hatchway I do not think this burning of lamps would have been necessary. The mercury reached 48° during warm days upon the approach of spring. Nearly all cellars need a drain, and it is just about as easy to make the drain so that it can be used for a sub-earth ventilator as not. My own cellar-drain is so arranged; but I have not allowed the air to pass in through the drain for the last two winters. Do you ask why? Well, I had my doubts as to its benefits; and, besides this, it lowered the temperature. Had the pipe been longer it might not have done so; it is only about 70 feet. I had 20 colonies buried in a clamp last winter. They were put in about the middle of November. A wooden tube, 3 in. square and about 8 feet long, extended from near the bottom of the clamp up through the covering of earth, and projected 4 or 5 feet above the surface. At the bottom of this tube was kept a thermometer, whence it could easily be drawn by means of a string. When the bees were first put up, the temperature in the clamp was 47°. It gradually sank, and in a week had reached 45°. Here it remained until steady cold weather came on, when it again gradually fell until it reached 42°, where it remained unchanged for nearly four months. When the warm days of

April came it gradually rose to 45°, at which point it was when the bees were removed. Now, the bees in this clamp wintered splendidly, and there were no fires and no supervision, and the conditions were the same as though they had been in an outdoor cellar. I am aware that some bee-keepers use a fire to warm their bee-cellars, and, with some cellars, this may be necessary; but with an underground cellar that receives a steady supply of heat from the earth, fires are wholly unnecessary; and all the supervision that is needed does not amount to any thing practically, so far as cost is concerned—at least, not to the man who lives at home winters.

Mr. P. speaks of the "wear and tear" of putting bees in the cellar and taking them out again. I fail to see where there is any "wear and tear." He further says, a cellar won't last always, and must be repaired. This is true of some cellars. A cellar stoned up, and under a building, such a one as Mr. Taylor's or Mr. Heddon's, will require no repairs for a lifetime. You, friend Root, speak of the cost of preparing the cellar for wintering bees; that the windows must be darkened; sub-earth ventilation furnished, etc. Candidly, my friend, do you, or does *anybody* know that all these things are needed? Do we *know* that a cellar must be dark? and if we do know it, is it expensive to darken the cellar? Where is the man who *knows* that sub-earth ventilation, or *any* ventilation for a bee-cellar is needed?

Friend P. says there are two "ifs" in the quotation from Prof. Cook; and then in the next sentence he (Poppleton) says, "Chaff hives are safe in severe winters if" (there it is again) "they are properly constructed and handled;" but the really weak point is this part of the argument is found in this sentence: "Many of us older heads have supposed that we had found the royal road to success, and would reach it, too, for a series of years, when some *climatic or food changes* would occur, and the goal would be still ahead." I wish to call attention to the part I have italicized. The two "ifs" in my quotations from Prof. Cook are surmountable. We *can* have the cellar right; ditto the food; but in outdoor wintering those climatic changes are an element of uncertainty, the damages from which can be only partly averted by chaff hives or protection of some kind. In the cellar we can have the conditions the same every winter. I have yet to lose a colony having cane sugar for stores, and wintered in a warm cellar, and by the methods that I now employ I can have the winter stores consist of so large a per cent of sugar, and that, too, in such a position that it will almost surely be used during the winter, and all with so little labor, that the damage of loss from unsuitable food practically amounts to but little. It is so slight that I prefer to take the risk rather than to perform more labor and take no risk. I will admit, that some honey is equal to sugar for wintering purposes; and I sincerely wish that friend P. could give us an article upon the subject of getting good honey for wintering our bees, and also tell us why he thinks that colonies worked upon the top-story plan do not winter so well; yes, and point out "the very obvious reasons" why neighbor Doane's bees did not winter so well as mine.

Yes, friend P., it is an experienced apiarist who can make it pay to spread the brood, if any one can. It is also true, that the time for doing this work comes before the rush of the honey harvest; and I do not doubt that, combined with spring protection,

many apiarists might find it profitable; but I feel satisfied that the same results, or nearly as good results, may be secured with no labor; and certainly no bee-keeper need spread the brood in the spring, simply for a lack of something to do. What I mean by accomplishing the same results with no labor is, using hives having a brood-nest of such capacity that a queen of ordinary prolificness can and will keep the combs filled with brood without "horse-whipping" her by spreading the brood. We can often increase our profits by increasing the number of our colonies, rather than by increasing the average products of those colonies we already possess. In other words, "securing the greatest amount of honey with the least expenditure of capital and labor" does not necessarily mean securing large yields per colony.

I will explain why I consider it more profitable to winter bees upon sugar when raising comb honey. The prices of extracted honey and sugar are very nearly the same; or, at least, they have been, hence the profit could not be very great, while the price of comb honey is twice as great. I am aware that many believe that twice as much extracted as comb honey can be produced, and perhaps this is true in a majority of cases; but those who are well up in the production of comb honey, and employ the best methods, know that they can secure at least three-fourths as much comb as extracted honey.

I feel now very much as though I had had my "say" upon this subject; and I should be very glad indeed to let some one else speak.

W. Z. HUTCHINSON.

Rogersville, Mich., July 20, 1887.

I am very glad indeed to know, friend H., that you have recently succeeded so well with clamps. But are you satisfied now just where the cause of your former failures lay? and do you think the clamp as safe, or safer, than a good cellar? and in regard to cellar wintering or outdoor wintering, have both you and friend Poppleton taken into consideration different localities? While it is no doubt safest in Michigan to winter in the cellar, I do not believe the climate of Ohio will warrant the same conclusion for our locality.

THE PAST, AND THE PROSPECT.

BRIGHTNESS THROUGH DISCOURAGEMENT.

MOST of the readers of GLEANINGS are aware by this time, no doubt, that the honey crop of this season is likely to be exceedingly short. My locality is no exception to the general rule, unless it is in being rather worse, if any thing, than the average. In fact, the season here has been most exceptionally bad. It opened badly. Fruit-blossoms produced scarcely a ripple on the apian sea. White clover came in abundance, but, except for two or three days, its blossoms remained almost unvisited by the bees. Basswood bloomed early and freely, but the taste of basswood honey never became perceptible in the hives. Mustard and sweet clover came at about the same time. For about two weeks the bees worked well on these in the early morning, continuing with less vigor on sweet clover throughout the day.

Mustard is gone now, and sweet clover, in the in-

tense drought that prevails, yields scarcely any honey. Strong colonies, devoted to extracted honey, are gaining very slowly. Colonies run for comb honey are doing nothing, except that some of them are putting a little into the brood-chamber. Ordinary colonies are not gaining at all; and many, I think, have less honey in their hives than they had in the spring. I have heard of several cases where bees were found starving during what is usually our best honey-flow.

As a matter of course, there has been little or no swarming. Only one colony in my apiary tried it, and that, on being returned, thought better of it and did not repeat the attempt. All colonies are unusually weak. Unless we have heavy rains soon, heart's-ease will fail, and with it our only hope of any income from bees this year.

What is the lesson to be learned from this? Dark as the prospect is, it is not without some points of brightness. In the first place, the markets will probably be cleared of all of last year's honey. This of itself is by no means a small thing in the establishment of better prices for this year's crop. Only those who have had a large experience in selling direct to retailers can have an adequate idea of the depressing effect on the market exerted by even a small quantity of unsalable honey. I can recollect instances where it would have paid me to have bought out a retailer's stock of honey at his own price, rather than let it remain on his hands, spoiling his trade, preventing the sale of other honey, and lowering its price. Now, if those who have any honey for sale this year would only hold it back until the market is bare of all old honey, and the demand for new begins to be urgent, they might realize almost, if not quite, as much for their short crop as they would have for a full one; at the same time preparing the way for better prices next year. Honey will probably be in greater demand this year than last, for the same drought that made a failure of the honey crop produced a great shortage in the yield of small fruits, so that there should be an unusual demand for honey as a table-sauce.

Many bees will probably starve the coming winter, which, I think, will be a good thing for bee-keeping as a whole. In fact, I know of only one thing that would do more to put bee-keeping on a sound and remunerative basis than a wholesale reduction of the number of bees kept, and that is a corresponding reduction in the number of careless and incompetent bee-keepers. I know this idea is not popular with some, but it is my honest opinion.

Although many of those who meet with losses will become discouraged and give up the business, there will be enough who will go at it again to make the trade in bees and queens good.

Look at it which way we will, I think there is much of encouragement to the careful and energetic apiarist. The present loss may be hard to bear; but when all things are considered, it may give greater results than a more apparent success.

So failure wins; the consequence
Of loss becomes its recompense.

At any rate, good management will go far to retrieve our losses and prevent them from becoming defeats. Stick to the bees, then, and give them the best of care. If there is any chance for a fall crop, be sure that the bees can make the most of it. Above all, be sure that your bees go into winter

quarters in as good condition as you know how to put them. To insure that, begin now.

Dayton, Ill., July 14, 1887.

J. A. GREEN.

Friend G., you are on the right track, I am sure. The short crop has brightened things here at the Home of the Honey-Bees already. The large lot of glassed sections of honey we have been trying in vain to sell for two years is now almost gone, and probably will all be gone before this reaches our friends. Every thing in the shape of honey, that has been standing idle for years back, most of it, is being moved off at a price that pays cost, interest on the capital that has been lying idle, and a little more. The scarcity of fruits in our own town has started a brisk local trade. For some years back I have been in the habit of enjoying droughts or excessive rains; that is, so far as I can enjoy any thing that harms my neighbor, for these things mean better prices. The dry weather has spoiled most of the cucumbers in the gardens of Medina, and, as a consequence, we are getting extra prices for the product of our vines; and thus, you see, the money we put into sub-irrigation a year ago is beginning to come back; and the cucumbers planted over those bog-holes are now booming. The real wide-awake bee-keeper need not be worried nor troubled. But we should also learn a lesson by having a little ahead to carry us over bad seasons. And we should learn a lesson about being in a hurry to make investments and to enlarge our business. Go slow and go sure. Keep in mind all the while that sickness, drought, floods, and tornadoes may be expected at almost any time. If they do not come, all right; and when they do come, you are, at least in a measure, prepared for them.

EXTRA-THIN FOUNDATION.

C. C. MILLER DISCUSSES THE WIDTH OF SUPERS,
ETC.

A FEW years ago I tried some extra-thin flat-bottom foundation, and decided against it. Afterward I tried some extra thin with natural base, and was not pleased with that.

This year I decided to use some flat-bottom thin, in spite of any objections, because I thought there could be less objection on the part of consumers to the thinnest foundation (I use sections full of foundation), and because the thinnest foundation would cost less per section, even if it cost more per pound. I have not had an opportunity to test it this year in a full honey-flow, for the worst drought ever known here has prevailed, and on the 20th of July there is less honey in the hives than when taken from the cellar. Only a very few colonies have stored any thing in supers, except some in the bait sections. But what little observation I have been able to make agrees with my former observations—that when bees have in their possession extra-thin foundation they are liable to dig holes in it and tear it down at the sides, at such times as they are storing little or no honey. I am inclined to the opinion, that, when honey is yielding well, this objection may not hold; but there are so many times when the difficulty may occur that I think I never

care to use extra-thin foundation again. I somewhat question whether bee-men themselves are not about the only ones who raise any objection to comb honey containing what is ordinarily classed as thin foundation, say 10 or 11 feet to the pound. Flat-bottomed foundation suffered more than that with natural base; but as they were not used in the same super, no positive conclusion could be reached. The experiment as described on page 517, by Mr. Root, seems perfectly fair and conclusive, except as to one particular. Were the two kinds of foundation used, exactly alike as to the number of feet per pound? and was the base of the same thickness in each case?

SIZE OF SUPERS.

On page 556, in *Our Own Apiary*, a department, by the way, which is always intensely interesting, the question is raised, whether the T super should be adapted to an eight or ten frame hive. I am inclined to think I should answer "No." The 1-lb. section having become so generally used, settles the length of the super. The width must be settled by the number of sections to be used; and for convenience in handling, and other reasons, I would not think of any thing more than $12\frac{1}{4}$ inches inside; and it is possibly worth considering whether there might not be some advantage in having it less. So I should settle upon the size of the super somewhat independently of the size of the hive, and, if necessary, make the honey-board, or something else, act as an "adapter" between the two. My hives are ten-frame, although they rarely have ten frames in them. They are $17\frac{1}{4}$ inches wide outside, and $20\frac{1}{2}$ inches long (not the best size), and the supers are $3\frac{3}{8}$ inches narrower, and $1\frac{1}{8}$ inches shorter than the hives. To make one fit the other, a stick $\frac{3}{4}$ inches square, and the same length as the top-bar of a brood-frame, is placed in the hive at the right place, to support one side of the super, or honey-board, rather; then a little stick laid across the back end covers partly or wholly the space left by the difference in length. When a super is put on, there may be anywhere from 4 to 8 frames in the hive; and if less than 8 there are not enough frames to be under the whole of the super. The best way is to fill out with dummies each side of the super, a close division-board shutting in a hive at the open side. So you see I consider the size of the hive and the size of the super as two almost independent things.

PIPING OF QUEENS.

I don't want to get mixed up with Doolittle and the other D's in a discussion, for I don't want to get worsted; but I can at least ask a few questions. Do we do well to throw away the old word "quabk"? Doolittle uses the word "pipe," or "peep," indiscriminately, as applying to the noise made by a queen, whether in or out of the cell. I wish I had a hive with young queens right by me, that I could describe accurately the noises made; but I will tell as nearly as I can what comes up from memory, and Doolittle can bring me up with a sharp turn if I get it wrong. If I am not mistaken, the old-fashioned way was to say the free queen was "piping," and that those in the cells were "quabking." In piping, the queen emits several sharp tones, the first one quite prolonged, followed by shorter ones; then the queen or queens in the cells quabk (pronounced the same as "quack," only giving a the broad sound as in *fall*), and this quabk is not merely a muffled peep, as the quabk consists of several tones of equal duration, quite short, as

compared with the piping, and of lower or coarser pitch. So if we admit this distinction in terms, would not the truth be somewhat like this: A single queen is heard piping, and is replied to, generally, before she has finished piping, by several queens quabking in their cells?

REMOVING SECTIONS.

Friend Aaron Brogler (page 510), when sections are well glued in supers, gently bearing down upon them with a small light lever will have no immediate effect; it would take a pressure of perhaps 50 to 250 pounds' weight to immediately start them, if applied over the whole surface. Striking at one corner readily starts it at that point, and then it is easy to follow up your vantage ground. If you are willing to take time enough, the gentle pressure may answer; for a superful of sections that will resist a weight of 500 pounds may yield to a weight of ten pounds if continued *long enough*, always supposing that the propolis is warm enough.

Thanks, friend Muth-Rasmussen, for your suggestion, page 544, as to getting the last section in the super. If the block of wood is too much in the way, as I think it might be, then I would have two separate pieces of tin, each bent something like this:

Emma sometimes uses two case-knives, but I think this might be better.

I agree with you, friend Root, as to the "too much machinery;" and in general nothing is needed but a little care and patience to get in the last section; but now and then you come to a refractory one that just *won't* go in, and for such cases you'd be glad to have some "machinery" ready to lay your hands upon.

C. C. MILLER.

Marengo, Ill., July 23, 1887.

In answer to your questions, friend Miller, I will say that our flat-bottom thin foundation runs from 12 to 15 feet to the pound, and our natural base about 10 feet to the pound. The base in the latter is not quite so thin. However, the difference in weight of the two makes is almost wholly made up in side wall. With these facts in view, perhaps my experiments, as related on p. 517, would be less positive. At any rate, I think we can be sure of this much: The bees always remodel the flat-bottom base before they make any use of it. Necessarily, I infer, they must expend more labor. That the bees did manifest an aversion to the one and a preference for the other in the same super, was clearly evident; though, as before remarked, the difference in weight per foot, as well as the peculiarity of the honey-flow, might have affected the result. We should be glad to hear from others who have tested the flat-bottomed foundation.—You say you would not have the inside width of a super more than $12\frac{1}{2}$ inch. As we have made them this season, our super is $13\frac{1}{2}$ inches, inside width. We can alter it to $12\frac{1}{2}$ inches, inside

width, with a very little change in the honey-board, and yet not increase the cost of either. As Dr. Miller has freely expressed himself, what think the rest of you? Are the advantages such as to warrant the change in the super?

THE QUEEN AS RULER.

DOES SHE GIVE THE SIGNAL FOR SWARMING?

WHILE reading R. B. Robbins' letter in GLEANINGS for July 15th, regarding the piping of queens previous to swarming, I was reminded of my own experience in this line.

A year or two ago I was standing by a chaff hive containing quite a strong colony of Italian bees, preparing to look through the colony. I had taken the cover off; and before I lifted the oil-cloth mat off the frames I heard the clear, distinct piping, or call, of the queen. She gave three or four loud calls—different from the *teeting* of young queens. Almost instantly the bees on the outside of the hive, and on the alighting-board, started with a rush for the inside of the hive, and in a very short time every bee was in the hive. I suspected what was coming, so I put the cover on the hive and waited for the next move. I soon heard another call from the queen, but not just like the other, or first call. Before I could count ten, out poured the bees in a torrent. The swarm was large, and I soon had it in a new hive. I then looked through the hive whence this swarm came, and found several queen-cells but no queen. Two days after, the young queen hatched out.

This is the second time I have heard the piping of the queen just before the swarm issued. The first time, the bees were in a hive where I could not examine the condition of the bees; but as soon as I heard the call of the queen, and saw the bees rush into the hive, I went to the house for help, and a hive for the coming swarm. When I got back the bees were out, and beginning to cluster. Whether the queen *always* calls this way before a swarm comes out, I do not know; but I have noticed many times that the bees lying out always go into the hive before the swarm comes out, and go in as though in response to some call or signal, to fill themselves with honey, I suppose. Excepting the times noted I have not been near enough to hear the queen, so I do not know about her piping; but I do know that I heard her call in both cases above stated.

Bees here are in an almost starving condition. Some colonies have less than a pound of honey. All of my queens are laying, as in springtime. I fear I shall have to feed or let them starve. I will kill them, before the latter shall happen.

Moweaqua, Ill., July 20, 1887.

D. C. AYARS.

OUR P. BENSON LETTER.

P. BENSON'S GRATE BEE-PAPER.

I AM gittin reddey to publish a noo paper. It will be devoted to bees, bee-keepers, aparrists, apaculcher, bee-keepin and kindered subjej. Terms invariablie in advance. It will be weakly. It will be entighteled The American Gleanings Magazeen and Advance Gide Bee Jirnal of Apaculcher.

It is with reluctants that I undergo this noo enterprize, but I feel it my dooty to yield to the noomerous solissyashens of my multitoodiness friends, whitich thay need a paper whitich will emboddy in a suksinked form the burning thots of I far advanst in the most advanst stages of apaculcher, whitich I am him, P. Benson, A. B. S., or to give my fool tightel, Apiculturistical Bee-Keepin Sighentist.

Sum bee-papers is published alreddy, but the edditors is defishent. For edditor it wants a noo man whitich will go at the root of things and ally to himself evry aid to clime the hill of sighents, I whitich will grasp the rudder with a firm hand, and soar grandly aloft in the grate possibilities of the futer of bee culcher, soar till the blew volted skies sirrounded his ambrosshell locks with vesper chimes of majestick sighlents, and all down the ages to the remotest end of time shall go resoundin the name of that lofty giant of intelleck, P. Benson, A. B. S., whitich is the responsive edditor of that well noan and popular paper herein described and set 4th as aforesaid in this prospectus.

This valooable paper will be an indispensable adjunk to evry aperry and bee-keeper. It will be printed on the 1st of the weak and paper of pinkish culler. It will print the highest prices for hunney whitich will stiffen the markets. It will print reparts of bigger crops of hunny than enny paper in existents. It will print loer prices for hunny than enny paper, whitich will make hunny so cheap that evry buddy will eet it and thus increase the demand, whitich will increeze the price to the projuicer. It will print reparts of faillyures, and this will projuice the feelin that hunny is skerce and evry buddy will want it and will be willing to pay enny price for it.

Subscribe for this grate paper now. The demand has bin alreddy so grate that the 1st number is eggstosed, but it will be give as premyum to them whitich sends in thair subscripshen befour Krismus. Send for this grate paper now. Evry buddy wants it and it will be impossible to supply $\frac{1}{2}$ the demand.

THE MODEL BE-PAPER.

The above seen is taken frum life and shows with what wrapped at10shun this paper is devoured by the entire family sircle on its weakly arrive.

Edditer and Proprieter.

THE QUEEN OF THE HOME.

HOW HER LABORS MAY BE LIGHTENED AND HER DUTIES BE MADE PLEASANTER.

FEW things that have ever appeared in GLEANINGS have interested me any more, Bro. Root, than the articles written by yourself and our good friends Prof. Cook and T. B. Terry, looking to the betterment of our homes, and especially to making lighter work and pleasanter life for the "queens of our homes." I am sure those writings will bear good fruit in many homes. I have studied much upon this matter, and I must confess yet to great ignorance. It is much easier to see what is wrong than to tell how to right it. I believe there are thousands of homes where a Henry Bergh is needed to arrest husbands for cruelty to—wives, where the husbands suppose they are doing about as well as good husbands ought, and if their eyes were opened they might do very differently. I am judging only by myself. Add to this ignorance a confirmed habit of carelessness on the part of husbands, and it's no wonder that wives feel jaded and discouraged. The fact is, that some relics of barbarism still remain, and we are not so far removed from the savage who looks upon his wife as his slave, no drudgery too great for her, if it ministers to his pleasure in the slightest degree.

We read with complacent approval the advice of those who tell the good wives how to welcome the husband home where every thing is bright and cheerful, the "snow-white cloth" is laid, and all that, the "neat ribbon at the throat," etc. Now, there's some sense in that, and a good deal of nonsense. The implied thought seems to be, that, under all circumstances, every thing in the way of ease and comfort for the wife must be set aside, and her gracious lord and master is to accept it as a dog snaps up a piece of meat, and then growls for more. There are plenty of times when a woman's work is in such shape that it is nothing short of cruelty for her to be obliged to straighten up every thing in apple-pie order, and get up a good dinner at the regular time, and in fine style. It is not a very unusual thing to hear something like this: "Mr. A. is not going to be home to dinner to-day, so we needn't make any fuss about it; just have a picked-up dinner. That will give us a chance to get along so much better with our work when we are so hurried." In this case the four or five members of the family are well suited with the dinner involving less work; but if the sixth member is present, in the person of Mr. A., the master of the house, an entire change of programme must be made, and the wife and mother lies down at night aching at every joint, with the somewhat doubtful compensation of feeling that Mr. A. has had his regular dinner.

A great many of our women have a pretty hard time of it at best, with work that seems to me more or less unnecessary; but it is a difficult thing to see the way out of it clearly. But if men had their eyes open they could many times help to make labor lighter. In the case mentioned above, if the husband should happen to notice that work about the house was somewhat pressing, he might say, "You're so busy to-day I don't believe I would make any elaborate preparation for dinner; just manage to make the least work about it possible;" and then after dinner he could say, and say it truthfully, if he felt as he ought, "Well, now, this is a

good dinner. I have really enjoyed it. Why can't you do this way oftener?"

It is not a very unusual thing in my own home to have meals that require very little labor. In the summer time it is more or less an absolute necessity, for the two ladies of the house, the two house-servants, and two of the field-hands in the apiary, are all one and the same pair. In the winter time, when they are particularly engaged at some sewing, some preparation for Christmas, or what not, and none of us feel that a very hearty supper is necessary, a waiter may be brought into the sitting-room, filled with all that may be needful, and perched upon the organ-stool, some milk or weak coffee heated on the open anthracite fire, and we all help ourselves in a very informal manner. This saves the trouble of starting a fire in the kitchen, setting the table, clearing off the table, and washing a lot of dishes. Now, my dear brother-reader, don't rush to the conclusion that because such things are done in my house, therefore the lady of the house is a very slovenly sort of housekeeper. I warmly resent any such insinuation; she's just as good as your wife, and takes great pleasure in a well-kept house. Moreover, she by no means deserves the credit of a state of affairs that renders it possible, on occasion, to make her work a little lighter. I want you to understand distinctly, that I arrogate to myself the credit by insisting at times, in a very peremptory manner, upon lightened labor, and condescending to show no disapprobation at any little move in that direction not suggested by myself. Neither do I want to make you understand that I'm a model husband. I'm not. I'm simply selfish, and can be happier myself, and get more work done, by having bright faces about me. A very little grumbling on my part, or showing by word or look that the full tale of what fashion, or what you may please to call it, exactly, would be made more pleasing to me, and it would be given ungrudgingly and without stint, at whatever sacrifice of health and strength. My brothers, very largely in our own hands lies the power to shorten or lengthen, to make bright or burdensome, the lives of the "queens of our homes."

Marengo, Ill.

C. C. MILLER.

Friend C. C., I agree with you exactly in your position to-day. Suppose two brothers were living together, and that they kept house, cooking for themselves, as often happens. Suppose, also, they should divide their duties so that one supplied the needful food. During hot weather, or during a time when they were greatly crowded with their duties, if they should see fit to decide between themselves to have occasionally a meal that required very little care or preparation, what would there be wrong about it? and wouldn't it be a Christian-like act for the brother who did not cook, to tell the other, under circumstances such as I have mentioned, that he would not mind having a simple pitcher of milk and a slice of bread for his supper, or, if the case might demand, even breakfast and dinner? It would simply be a brotherly act. Now, then: Ought not a man to be as self-sacrificing and thoughtful of his wife as of his brother? The question is really ridiculous. The queen of the home stands in a nearer relationship to the "lord of the home" than any other that can be mentioned. Just before marriage, we of the sterner sex are in

the habit of making little speeches something like the following: "My dear one, this broad universe can furnish no pleasure like the one of caring for you, waiting on you, being near you, and ministering to your wants and comforts so long as a kind Providence shall permit me to live and breathe." No doubt we didn't all of us use just exactly those words, but did we not think as well as say something that came pretty near it? Now, to come down from the honeymoon to something plain and practical, let me suggest to you how simple a meal may be occasionally partaken of, and, after all, one that suits me to a dot. It is a pitcher of cold milk and a bowl of cerealine. You probably won't consume the whole pitcher of milk (that is, unless you are a very big man with a very strong appetite), therefore the pitcher can be set back into the refrigerator or cellar, without any washing. The bowl and one spoon will comprise all the dishes to be washed for each individual. I don't quite understand it, but this cerealine is excellent food, without any cooking whatever. Pour the milk on it and let it stand two or three minutes, and it is ahead of any cold mush to eat in milk I ever came across, and I tell you I am very fond of cold mush and milk too. This cerealine is sold at nearly all the groceries, and costs only 16 cts. for a package of five pounds. Now, some of you may not fancy such a supper as this, even if I do. Oh, yes! I want to say, also, that it is tiptop to work on. I can go and work in the garden after such a supper as well, or better, than on any other I know of. My wife, however, sometimes feels sorry for me (or, at least, she says so, and she is always truthful), and so she gives me a dish of raspberries, huckleberries, or something of that sort, to sprinkle in. This makes the pie, you know, or fruit; and as they are sprinkled out of a pint basket right into the bowl of milk, even this addition does not make any more dishes to wash. If you have not the cerealine handy, you can substitute a slice of nice bread. Cerealine is, however, I believe, sold in almost every grocery in the United States at the price I have mentioned, or a little more.

MRS. HARRISON TALKS TO US ABOUT GASOLINE-STOVES.

ALSO A WORD IN REGARD TO CARPET-SWEEPERS, PORCHES, ETC.

MR. EDITOR:—I have been very much interested in what has been written with reference to saving women's work, and especially Prof. Cook's kitchen. I cast about to see how I could lighten labor, and took gasoline-stoves under consideration. Women who had used them spoke highly of them as saving from cleaning up soot, ashes, coal, kindlings, etc., and the labor of making fires. After examining many different kinds I purchased one which I thought had the most good points, and I call it my "hired girl." It is very obedient and satisfactory. I was afraid of it at first, both for myself and the "orphans;" but their curiosity was soon satisfied;

and as the fire is all put out by turning down the reservoir to fill it, I think it is safer than a kerosene-lamp. On cool days I make a fire in the coal-stove, and use it; and I find at night that I am a great deal more tired than when I use the gasoline. Bituminous coal costs, delivered, \$1.50 a ton, and gasoline 15 cts. per gallon. Early in the season, 13 cts. Dealers in stoves are also interested in its sale, and kept the price down until they had sold many stoves.

I also carpeted the kitchen. I tried this once before, but the dust from soft coal was such a nuisance that I took it up, but get along with comfort, using gasoline. If I were a poet I would sing its praises—such a relief from heat! One room does now where it took two before; and such a saving of steps while ironing! The ironing-board can be placed within reach of the irons.

I don't think any mother who does her own work should sport many porches, especially if they are near a driveway. No lady loves to see them dusty, and harboring spiders, etc.; and to avoid this she must constantly clean them. They should be indulged in only by those able to hire a man to take care of a horse, carriage, wash windows, walks, etc.

Carpet-sweepers lighten labor, but they do not fill the bill as a perfect sweeper. They do not sweep corners or near walls. If a room is thoroughly swept with a good brush broom once a week, and dampened meal be thrown upon the carpet, the sweeper can be used the rest of the time. It is very convenient to gather up clippings, ravelings, etc., and indispensable in a sick-room. Every woman should have one.

Bees barely make a living this season, owing to the severe drought last year and this; and I get fresh air in the hammock, in lieu of running the lawn-mower, hiving bees, taking off sections, etc.

Peoria, Ill., June 22.

MRS. L. HARRISON.

MORE KITCHEN CONVENIENCES.

WHAT CAN WE DO TO LIGHTEN THE HOUSEHOLD DUTIES?

FRIEND ROOT:—When farmers go to visit their friends they are apt to spend much of their time looking at the crops, or the stock or barns. This is well; but they ought also to examine the home, and its surroundings and equipments. Why shouldn't we be just as anxious to get suggestions as to how we could make our homes a little pleasanter, or a little more convenient for our wives and daughters to work in, as to learn how best to fix our barns, or take care of our crops? In fact, ought we not to take much better care of our dear ones than of our stock? But do all farmers do this? I fear not. Let me picture a case that I saw with my own eyes, and which has too many duplicates. The farmer showed me through a fine—yes, magnificent barn, with all the latest improvements and conveniences for the comfort of the stock. His horses were fat, and showed that they were never overworked. In the harness-room I noticed nets to keep the flies off from them when they were at work. When in the house I asked to see the kitchen. Were there screens on the windows and doors so his wife could work without being bothered with flies? No. Were there any of the numerous little conveniences that are found in the best kitchens nowadays? There were not. Did

the good wife look as hearty and well kept as the fine horses in the barn? Not by a good deal. The poorest-kept stock on the farm was in the kitchen. I was telling of this at an institute a few months after, when a man in the audience said: "Do you not understand all that, Mr. Terry? If one of those horses should die from overwork and poor care, there would be \$200 dollars gone. If the wife should die, he could get another for nothing."

I think that was a pretty harsh judgment. I should rather say that such men, in their eagerness and strife to get ahead, have been thoughtless. They do not see these things as an outsider does. They have meant well, but have got a little off the track. I hope every farmer who takes GLEANINGS will eye his wife closely, and see if there are any grounds for saying she is not well kept. I hope he will go into the kitchen, in particular, and see if it is fully up to the times in conveniences and comforts; and then whenever he visits a friend I hope he will look the home over carefully. If there are any little improvements that he hasn't got, may he go home and plan to get them as fast as he can. If his friend's home is lacking in some little things that go to make the work lighter and pleasanter, he might quietly suggest them to him. Also, he might write to you for publication what he did or what he saw abroad that was valuable, and thus let his light shine to brighten homes, perchance, that he could never otherwise reach.

This reminds me of some things I saw in a kitchen away up in Evansville, Wis. When at an institute near there I talked to the farmers as much about improving their homes as their crops, so Mr. B. S. Hoxie, a well-known architect and builder, invited me to see his home. There was one thing that many a farmer's wife sorely needs, and that was a dumb-waiter, as they are called. I do not remember seeing any mention of one in GLEANINGS since I have read it. This waiter is simply a long box, say two feet square and six feet long, open on one of the sides, and with shelves in it. It is hung with weights and pulleys, so that it can be let down from the kitchen or pantry into the cellar, or drawn up, easily. The good wife, after a meal, can draw up the waiter and put on it every thing that needs to go to the cellar, and thus save herself many a weary step. A box of potatoes, the butter, lard, etc., can be kept on it so that she need not run down cellar very often. I have seen my wife go down cellar at least half a dozen times while getting a meal and clearing it away. I sometimes think she might plan to take more at once, but it is easier, perhaps, for me to think so than for her to do it. I had never heard of a dumb-waiter, or, at least, not so as to fully understand its value, when we built our house, so we did not get one put in. After having seen them in use in several homes we have decided to have one in our pantry soon. It is a very simple affair. It works just like a sash in a window-frame hung with weights and pulleys. The weights balance the weight of box and contents, so it will stand anywhere, up or down. The space into which the waiter comes may be inclosed, both above and below, with a door on one side, if it is desired. The cost need be but a few dollars. I saw one last winter in a dining-room, as there was no cellar under the kitchen. It was inclosed in a fancy manner, and looked like a little china closet. You may have one in your fine home, friend Root. If so, you would do a good deed to give some pictures of it,

so all could see that it is simple and not beyond their reach.

There were lots of other nice things in Mr. Hoxie's kitchen; but I will stop to speak of only one that was entirely new to me. It was the arrangement of flour-box and shelf for making up bread, etc. On one side of the kitchen I noticed a little shelf about one foot wide by two and a half long. The space beneath was inclosed, and there were two doors with their trimmings. I couldn't make out what it was for, so I asked. Friend Hoxie went to it and let down over the top a large leaf, or bread-board, that was hinged to the wall and fastened up, and which I had not noticed. When this was let down it was just the right height to make up bread on. When through, one had only to hook it up and it was put up out of the way, and the used side back. I was so interested in looking at this that I forgot the little doors below until my friend opened one, and there was the flour right where you could dip it on to your board easily and not get any on the floor. This was by all odds the neatest and best flour-box arrangement I ever saw. It is Mr. Hoxie's invention, and not patented, and he would be pleased to have every one use it. I give a cross-section view of the two boxes in the inclosed space

CROSS-SECTION OF FLOUR-BOXES—TOP VIEW.

under the little shelf. The shelf is held up by a board down to the floor at each end. The front and end of each box, B, C, are made of wood. The curved side, D, which has to be curved in order to open, you know, is made of tin. The hinges are at A. The box swings right around out. E shows the end-board that holds up the shelf. The dotted lines show bread-board down and one flour-box open. I have just thought that it would be nice to put sugar in the other box. Of course, these boxes want to fit exactly, so no dust can get in.

Mr. Hoxie has built a great many houses in Evansville—no, not houses, but homes. He has made it a life-study to give a man the most conveniences and comforts possible for the money. Of course, I greatly enjoyed visiting such a man's home.

T. B. TERRY.

Hudson, Ohio, July 16, 1887.

Friend T., we have no such dumb-waiter as you mention, in our house, but we have two of them in the factory. One connects the dining-room with the kitchen, and I don't know how we should get along without it. During dinner-time, the cooked food is sent right up to the waiters; and when dinner is over, the dishes and all surplus go right back down into the kitchen. We will try to give you a drawing of it in another number, including a description of some little device of our own to make it convenient. The other one carries the printed sheets from our large printing-press, upstairs to the folding-room; and when "paper day" comes, and especially if it should

be a little late, I tell you this dumb-waiter has to do considerable business. They are indeed very great helps. If the whole apparatus could be made by machinery, so as to be shipped to customers, with the necessary castings, weights, cords, etc., it would be, very likely, the cheapest way they could be got up. We will try to look into the matter a little. In using ours we always have an attendant above and one below. Ours are arranged to work so smoothly we send up and down, milk, eggs, and every thing required; but the waiter moves so steadily that nothing is ever slopped or broken by starting or stopping.

FAILURE OF THE HONEY CROP.

MRS. AXTELL WRITES IN REGARD TO HONEY-DEW, FERTILE WORKERS, SUGAR FEEDING, ETC.

MR. AXTELL and I have failed in securing much of a honey crop this summer, on account of the drought. Bees were in good condition the first part of June; and if we could have had one or two more good showers of rain, by the first of June, we probably should have had our usual amount. However, the bees got enough to crowd the brood-nest, so they are provided for. Had our hives only a small brood-nest we should surely have had to feed sugar before our bees could gather freely again. Pastures are brown, and almost dried up bare.

While Mr. Axtell was back on the farm one day this week, near a thrifty osage-orange hedge, he heard a humming of bees. He lifted the limbs of the hedge, and peeped in to see what it was that called the bees there. He saw the leaves in places covered with a sweet, sticky substance. It was not over all the leaves, but more in spots. Just above the leaves that had the honey-like substance were thousands, I suppose, of one kind of aphides. They were white; and on shaking the limb they would jump like grasshoppers, unlike any I ever saw before. There was so much white fuzz, or dust, upon them they made the leaves or limbs they clustered on white. I do not think there were enough to cause bees to store any in sections, as they seem to have entirely left off storing surplus; but they were very lively, flying as if after honey. It seemed to me a wise providence to thus in time of drought provide for even the little bee.

FOUL BROOD, AND SUGGESTIONS REGARDING.

We sympathize with you in your being so unfortunate as to have foul brood in your apiary. As your colonies seem to recover, and you appear at times to get rid of it, I can not but think there is somewhere in the vicinity of your bees some careless bee-keeper who has it. Perhaps he may be a farmer with a few hives who does not look after his bees, and occasionally a colony has it so bad that it dies, and leaves the honey; then, of course, the neighboring bees would come in for their share and thus spread it. It seems to me I would try feeding phenolated syrup, and keep it up for a while—enough to reach a little to all the bees in the neighborhood, if you should have any reason to fear the above dangers mentioned were possible.

LAYING QUEENS FOR SWARMING TIME.

Making nuclei and rearing young queens before swarming time, so the queens are all ready for use, is a nice thing. It is very easy then to manage an

apiary, when one has plenty of young queens already in nuclei awaiting swarms. It is entirely another thing when one has all the bees he desires, to find his honey harvest suddenly cut off with no swarms. It was precisely in this situation that we found ourselves this season. We have accordingly decided that, in future, we shall be very careful about raising queens and dividing up colonies into nuclei, unless we are pretty sure to have a honey-harvest. If the spring were quite wet, and the clover abundant, I suppose we should be pretty certain of a honey harvest, which always brings with it more or less swarming.

This time I do not mind having made so many nuclei as I would if I had broken up good colonies. As it was, I used only the colonies that had failing and rejected queens; and this leads me to mention that Mr. Axtell and I much prefer home-bred queens; that is, queens raised in our own apiaries. Queens that have come to us through the mails are invariably short-lived, and seldom build up into choice colonies. We think this is because of the confinement, and perhaps of too much shaking by the postmasters. We do, however, approve of getting a queen to raise queens from occasionally.

In the spring we had several queenless colonies which I purposed to build up strong. Although I gave them young bees I could not get them to start cells like bees that had not been queenless long. I never had tried queenless colonies before; that is, queenless for so long a time as those may have been. Possibly the spring had something to do with it, as it had been unusually dry.

FERTILE WORKERS.

We found one colony that had fertile workers in the spring. I gave them a comb of brood with adhering bees, but the fertile workers went ahead laying all the same; then we gave them a comb of larvæ, eggs, and a queen-cell with adhering bees. This time they destroyed the cell, and the fertile workers still held sway. It being a fair colony, and I had given it brood so much that I disliked to waste the bees, I took them to a hive with a rejected queen, which I meant to replace soon. I brushed the bees of the fertile-worker colony all down at a distance in front, so the young bees and the fertile workers would crawl into that hive. The young bees would be received, but the fertile workers were killed, and the old bees that were not fertile workers flew back home, and that was the last of the fertile workers in that hive. In a few days I opened the hive and found nice cells started upon the combs I had given them. They had a young queen in a few days.

SUGAR FEEDING.

Mr. Axtell and I think bee-keepers ought, if possible, to entirely discard feeding sugar to bees, because of the growing distrust there is in the minds of people about sugared honey. Only a few weeks ago we received a letter from an intelligent Christian man in Chicago, wishing our word for it that our honey was strictly pure. He wanted to be sure of it before he recommended it to others, as he was expecting to handle our honey this year. We even felt sorry to tell him we used small starters of comb foundation, and sent him a piece about as large as we generally use for a section, as we use only small starters. He wrote as if people thought there was a great deal of adulterated honey. We wrote him as well as we could, telling him we did not think the comb honey offered on the market was ever manu-

factured; and as for the honey in the comb being adulterated, we thought that was never done to any amount; that some bee-keepers did feed their bees refined sugar for wintering, but that, probably, was all consumed, and but the merest trifle could ever find its way, if any, into the section honey; that we had not for several years fed one pound of sugar or other sweets beside their own honey gathered from the flowers.

We believe if all bee-keepers could constantly affirm, that they feed no sweets whatever, but were always careful to let bees have more than enough of honey for their sustenance the year round, the adulterated and sugared honey we so often read of would soon die out.

If at any time we fail to keep enough for them to live on, and are obliged to feed, let us do so, but keep silent about it and not report it to the world for everybody to read, but see to it that we never need do so again. Let us also use as little foundation in section honey as possible, and say less about that.

MRS. L. C. ANTELL.

Roseville, Ill., July 1, 1887.

I agree with all you say, my good friend, but I suppose you know this same matter of foul brood makes it desirable, many times, to feed sugar instead of honey. If there is foul brood in your apiary, you do not want to feed your own honey, with the chance of starting the disease again, when you can purchase sugar cheaper than can not start it; and if you are obliged to purchase something to feed, as many bee-keepers are obliged to do such a season as the present one, there is more or less danger in purchasing honey. I know it sounds bad to talk about bee-keepers buying sugar by the barrel, to feed their bees; and I agree with you that it behooves us to say as little about it as possible; that is, do not needlessly introduce the subject. If, however, anybody inquires about it, tell them the plain truth, that you do feed your bees sugar in preparing them for winter, during poor seasons, but that you take such pains that it is absolutely certain that what you sell as honey is by no possibility sugar syrup.

CARPETS VS. BARE FLOORS, AGAIN.

A PAINTED CARPET.

IN GLEANINGS for June 15, I noticed particularly the article, "Carpets vs. Bare Floors;" and if you will allow me, I should like to say a few words on the subject of floors.

A few years ago we had to spend about half of our working time in scrubbing, sweeping, and dusting; and as I found my strength yearly decreasing, and I could not get half as much time as was really needed for other things, I made up my mind there *must* be a change made in some way, and this is the way it was accomplished: In the first place, I covered my kitchen table with oil cloth (and that alone was a paying investment, for it has saved me many a backache); then I carried an old brussels carpet to an empty room in the tower; and after stretching and tacking it down wrong side up, I gave it three coats of good light ochre paint, and left it there four weeks to get thoroughly dry and hard, after which I tacked it down on the kitchen floor. I find it makes the nicest kind of a floor

covering for a kitchen, as it is so easily cleaned, and it is so durable. It has been in constant wear over three years, and the paint has not worn through anywhere yet.

I next turned my attention to the dining-room. It was a room that we used constantly, so that it not only required a great deal of sweeping and dusting, but it cost us quite a sum to keep it decently carpeted. We first painted the floor, but we did not like it very well, for the flooring was poor, and paint did not entirely hide its deficiencies; so a year ago we had a new floor laid down over the old one. It was of well-seasoned ash boards, about three inches wide; and before laying we stained half of them blackwalnut color, and after it was down we soaked it well with a mixture of oil, turpentine, and beeswax. We think now it is the prettiest room in the house, and it is certainly the cleanest, for we have scarcely any dust. I bought a few remnants of brussels carpet for fifty cents a yard, and put around in the parts of the room used most; these are light and easy to shake, and are pretty too. So, now, as the walls are painted, and the butternut woodwork varnished, housecleaning in that part of the house does not appall me.

MRS. C. B. HAYWOOD.

Ypsilanti, Mich., June 21, 1887.

BULL'S DEVICE TO REMOVE SECTIONS FROM SUPERS.

ITS MODE OF CONSTRUCTION.

IN compliance with the request of some parties who have written to me for a more detailed description of my machine for removing sections from supers, mentioned on page 342, GLEANINGS for May 1st, I have promised that, if the editor permits, I would endeavor to give the desired information through his columns, so that one explanation might answer for all who wish to know about it. Although the machine is not intricate, yet I think it can be more easily explained and better understood by the use of illustrations, so I will endeavor to give a rude sketch, or outline, of the different parts, to assist in conveying, if possible, a clear idea of its structure and workings.

The frame of the machine is composed of four pieces—two end-pieces, one bed-piece, and one top-beam, all of which should be made of 1½-inch plank, after being dressed on both sides. Pine or basswood will do. The dimensions may be varied to suit circumstances. If you wish to stand up to work, make it high enough to be convenient for that purpose; if you prefer to sit down when emptying supers, make the end-pieces shorter.

Fig. 1 is a diagram of one of the end-pieces, which should be 15 in. wide at the lower end, and 6 in. wide above the bed-piece. The distance between the bed-piece and top-beam is 22 in., the lower part to be of such length as will give the desired height to the bearing-

FIG. 1.*

* The diagrams are not made exactly to the scale; the reader will, therefore, get his exact dimensions from the context. Editor.

board, which is to rest on the bed-piece; a, a, a, are mortises to receive tenons on the bed-piece and top-beam; b, b, rabber, $\frac{1}{4}$ in. deep, whole width of the end-piece, to form a seat for the ends of the bed-piece and top-beam, to keep them from warping out of shape, and to give firmness to the frame; c, c, are cleats fastened to the end-pieces with screws, to serve as guides to hold the follower in its proper place when it is pressed upon the super; d is a round hole to receive the gudgeon of the cylinder. This hole ought not to be made quite through to the outside.

FIG. 2.

The diagram above shows the bed-piece, and is represented by Y in Fig. 6. It is $1\frac{3}{4}$ inches thick, $24\frac{1}{2}$ long, and 15 wide; e, e, e, are tenons to correspond with the mortises a, a, in Fig. 1, and reach through far enough to receive a pin through the holes f, etc., outside of the end-pieces; g, g, are holes for ropes to pass through, and connect the follower with the cylinder; h, h, are dowel-pins to hold the bearing-board in place.

FIG. 3.

Fig. 3 is the top-beam, $24\frac{1}{2}$ inches long, 6 wide, and corresponds to U in Fig. 6. The hole in the center, at I, is to allow the passage of a rope, S, in Fig. 6, to connect the follower with the spring, to draw it upward out of the way when placing the supers upon the bearing-board. The follower is composed of three pieces—one sliding-beam and two presser-feet.

FIG. 4.

Fig. 4 represents the sliding-beam. It should be made of hard wood, 24 in. long, 6 in. wide, and one inch thick. J is a staple or hook to receive the rope (S, Fig. 6) attached to the spring above; the small hooks beneath are for the ropes or straps to connect with the cylinder R, Fig. 6; l, l, are gains, or notches, $\frac{1}{2}$ inch deep, to form a seat for the presser-feet, and to hold them in place; m, m, are holes for pins or bolts to hold the presser-feet fast to the sliding-beam.

Fig. 5, corresponding to Q, Fig. 6, shows the form of the presser-feet. These should be made of some kind of hard wood, 10 inches wide, 11 inches high, and $\frac{3}{4}$ of an inch thick. A mortise is made at the upper end, 5 inches deep, one inch wide, and open at the top, as shown. A hole is bored through where the dotted line is seen in the notch. These presser-feet stand at right angles to the sliding-beam, the notch l, Fig. 4, fitting into the notch, or shoulder, seen in Fig. 5. A bolt or pin passing through the hole indicated by the dotted line, holds the presser-feet securely to the sliding-beam; and this constitutes the follower. When the

machine is put together, the ends of the sliding-beam are placed between the guides, c, c, Fig. 1, which form grooves in which it slides up and down when in use.

The cylinder, indicated by R, Fig. 6, may be made of a piece of solid wood 24 inches long and 6 inches in diameter. It should be turned off very true and round, of equal size at both ends, having an axis, or gudgeon, at each end, to fit into the hole d, Fig. 1.

FIG. 6.—BULL'S MACHINE COMPLETE, FOR EMPTYING T SUPERS.

The front side of this cylinder must be in a perpendicular line with the center of the sliding-beam of the follower. Two ropes (a piece of clothes-line will do) are attached to hooks on sliding-beam, Fig. 4. They then pass down through the bed-piece at g, g, Fig. 2, and fasten to the cylinder near each end, as shown in Fig. 6. A third rope is fastened to the cylinder at or near the center, wound once or more around it, as shown. A loop is made in the end to receive the treadle, V, Fig. 6. Any suitable stick 6 or 8 feet long will answer for the treadle. Insert one end into the loop in the rope; let the other end rest on the floor, back of the operator. When the treadle is pressed downward it will cause the cylinder to revolve in such a manner as to wind up the ropes which are attached to the follower, and draw it downward with equal force at both ends. It can not draw one end any faster than the other. The guides hold the follower from canting sidewise, thus obviating all danger of twisting the super and breaking the sections or comb.

TO MAKE THE BEARING-BOARD FOR THE T SUPER.

Take four pieces, $1\frac{1}{4} \times 3\frac{3}{4} \times 11\frac{1}{4}$ inches. Nail on to two sides of each of those blocks a piece of board $\frac{1}{4}$ inch thick, $4\frac{1}{2}$ long, and $11\frac{1}{4}$ wide, thus forming a sort of box without ends, $11\frac{1}{4}$ inches long, $4\frac{1}{2}$ deep, and $3\frac{3}{4}$ wide, outside measure. These are for the sections to bear upon when the super is being removed, and so constructed that all the pressure will be near the corner of the section, so as not to spring the bottom-bar and break the comb.

Those blocks are all set upon a bottom-board, and spaced off to correspond with the rows of sections in supers, being careful to have the end of each block in line with all the others. When properly placed they should be fastened with screws to the board. A little more than $\frac{1}{2}$ inch of space is allowed between these blocks for the passage of the T tins in the supers. When completed, the bearing-

board will present the appearance of X. Fig. 6, only there should be four divisions instead of three, as shown.

TO MAKE A BEARING-BOARD FOR WIDE FRAMES.

Take a piece of plank $2 \times 3\frac{1}{2}$, and 19 inches long. Cut two pieces of boards 17 inches wide, 4 long, and $\frac{1}{4}$ thick. Nail these on to the edges of the plank, having the grain of the timber in the boards run crosswise of the grain in the other, which will give much greater strength to the board. When nailing together, allow the plank, which forms the bottom, to extend one inch beyond the side-boards at both ends, as shown at W, Fig. 6. This forms a sort of box with open ends, 2 inches deep inside, 17 inches long, and $4\frac{1}{2}$ wide, outside measure, which is a little scant the inside dimensions of the wide frame. It is now ready for use, except that each bearing-board should have two dowel-pins in the bottom, to fit into the holes h, h, in bed-piece, Fig. 2, to prevent it from moving out of its place when in use. Great care should be exercised to get those dowel-pins in the right place; and perhaps the surest way to do that would be to set the bearing-board on to the bed-piece, place a super on it, bring the follower down to the super, to see if they meet just right; then pass the point of a bit up through the bed-piece and bore into the bearing-board, being careful not to let it move while doing this, and it can not be far out of the way. The dowel-pins should be driven tight into the bearing-board, but fit loosely in the bed-piece, so as to be readily removable.

To remove sections from wide frames, the frame with sections must be laid down upon the bearing-board flatwise, with the separator on the under side. The presser-feet of the follower bear upon the ends of the wide frame, which slips down outside of the bearings; and the separator goes down inside between them, and the sections will be left free and clear, resting on top of the bearings. The operation is performed in much less time than it takes me to describe it.

The process of emptying the T supers is also very simple. Set the super upon the bearing-board; place one foot upon the treadle, and bear down. If every thing is in proper order, the sections will all be out of the super before you hardly realize what is being done. To insure success, every thing should be made with some degree of accuracy.

JOSHUA BULL.

Seymour, Outag. Co., Wis., May 24, 1887.

THE NATIONAL BEE-KEEPERS' UNION.

WHAT IT IS, AND WHAT IT HAS DONE FOR THE BEE-KEEPER.

WE are glad to note, that the National Bee-Keepers' Union has fully demonstrated its usefulness and its ability to defend the rights of its patrons. Through this medium of strength the bee-keeper has more than once been enabled to accomplish what he could not have done single-handed. While we do not favor trades-unions in general, we must say that the Bee-Keepers' Union, under the present efficient management, has done good work for the cause it represents, and that, too, without the evil results which have been so characteristic of other trades-unions. It

is with pleasure, therefore, that we make the following extracts from the Second Annual Report:

To review the work of the National Bee-Keepers' Union at the end of the second year is a very pleasing duty, for we do not discover any thing which could have been done more satisfactorily—the results having been all that could be desired.

THE UNION VICTORIOUS EVERY TIME!

In all the attacks against the pursuit of bee-keeping, which the National Bee-Keepers' Union has deemed it expedient to vindicate, it has scored a victory! What no individual apiarist could have achieved single-handed, it has satisfactorily accomplished in a short time.

In the face of this showing, it is strange that any bee-keeper should hesitate to become a member of this organization. It ought to have thousands of members where it now has only hundreds. It is to the interest of every apiarist to become a member. Nay, it is not only that, but it is a duty, which, if neglected, will operate to his or her disadvantage. As the Union will defend only its members, who became such before any lawsuits were commenced against them—all should take time by the forelock, and join the Union at once!

MAILING QUEEN-BEES AND ATTENDING WORKERS.

The first thing which demanded the attention of the Union during the past year was the action of the postmaster at Griffin, Ga., who refused to receive a queen-bee in the mails, because of the attending workers, the postal regulations permitting only queen-bees in the mails—not drones or workers!

The Manager of the Union, Prof. Cook (Vice-President), and the Hon. Edwin Willits, each made an appeal to the Postoffice Department at Washington to have his action overruled. It was only a technicality; but as necessary attendants were essential when mailing queen-bees, it was a vital point to apiarists.

The General Superintendent of the Railway Mail Service ordered the regulations to be revised so as to read, "Queen-bees with necessary attendants," and so advised the postmaster in Georgia, the Manager of the Union, and others. Since that time we have heard no complaint on that score.

SENDING QUEENS TO CANADA.

Complaint was made that queen-bees sent to Canada had been stopped at Suspension Bridge. This was referred by the Manager of the Union to the Superintendent of Foreign Mails, and that difficulty was promptly removed. It was occasioned by the officiousness of the postmaster at Suspension Bridge, N. Y., and he was notified to "let the bees pass." So ended that trouble.

CALIFORNIA FRUIT-BEES TROUBLE.

The Bohn case, mentioned in my last Report, was appealed to the Superior Court. The decision there given was on technicalities, and practically ended the difficulties. The expenses of the suit and appeal amounted to \$384.50; of this the Union has paid one-half and Mr. Bohn the other half. In this case the resistance of the Bee-Keepers' Union was too much for the fruit-growers—and that trouble which was proclaimed by a Nebraska apiarist to be too much for the Union to compete with is now all conquered, the raisin-growers admitting that they were mistaken.

Foolish warfare against bees seems to be the rage! The idea that fruit suffers because of the presence of bees is simply ridiculous. The good they do in fertilizing the fruit-trees far outweighs any possible evil that may follow their presence.

REMOVAL OF BEES FROM CITIES AND VILLAGES.

M. Darling, of Waterbury, Conn., was sued for \$500 damages by a neighbor, and to compel the removal of his bees. The case was instigated by malice and jealousy, and was dismissed as soon as it was discovered that he was backed up by the National Bee-Keepers' Union. The expenses were \$50, of which the Union paid one-half.

S. W. Rich, of Hobart, N. Y., was sued by a jealous and disagreeable neighbor for \$1500 damages, and also to compel him to remove his apiary outside the city limits. This suit is defended by the Union, and is as yet undecided.

C. C. Richardson, a gardener, was sued for keeping honey-bees on his land in Tipton, Ind., alleging that they were a nuisance. This was also de-

fended by the Union, and, as a result, it was dismissed by the court. The costs were \$20; one-half of it was paid by the Union. This is the case which was so badly misrepresented at the Indianapolis convention by an officious neighbor, and it is with much satisfaction that I am now able to say that the Union was too much for the enemies of the pursuit of bee-keeping.

The city council of Fort Wayne, Ind., passed an ordinance against keeping bees within the city limits. If enforced it would practically wipe out the pursuit of bee-keeping there. Such a pressure was brought to bear by the bee-keepers, backed up by the Union, that the ordinance is a dead letter, and it is expected that it will soon be repealed, if it has not already been done.

In Arkadelphia, Ark., the City Council ordered Z. A. Clark to remove his bees from within the city limits within 30 days. Major J. L. Witherspoon, ex-Attorney General of Arkansas (who stands at the head of the Bar of the State), was employed to attend to the matter on behalf of the bees. The National Bee-Keepers' Union backs up Mr. Z. A. Clark to fight the case on its merits.

The thirty days have expired, and the bees are still there. Public opinion is strong against their removal, and the newspapers are teeming with ridicule of the order to remove them.

The Union will stand by Mr. Clark in this matter, and see it through, for it would be very detrimental to the pursuit to allow a decision against bee-keeping to be put upon record on the plea of its being a nuisance.

PROPOSED LEGISLATION IN MICHIGAN AGAINST BEE-KEEPING.

The McCormick bill introduced in the Legislature, "intended to wipe apiculture out of Michigan," as Prof. Cook stated it, raised such a buzzing about his ears that it was tabled on his own motion, and there died. The President of the Union (Mr. Heddon), as well as Vice-President Cook and the General Manager, all labored with Mr. McCormick to bring about the before-mentioned result.

Here we have another result of the benefits to be derived from organization and combined effort. The members of the Bee-Keepers' Union have many triumphs to feel proud over, and this adds another laurel.

FINANCIAL STATEMENT FOR THE TWO YEARS,

From July 1, 1885, to June 30, 1887.

From 620 memberships at \$1.25 each	\$775.00
Paid S. I. Freeborn's suit.....	\$131.00
Paid G. Bohn's suit.....	192.25
Paid M. Darling's suit.....	25.00
Paid C. C. Richardson's suit.....	10.00
Printing, stamps, stationery, etc.....	192.50
Defense Fund—Cr.....	\$261.25
Defense Fund—Dr.....	37.00

Balance on hand July 1, 1887.....\$224.25

I estimate that the amount remaining in the treasury will about cover the expense of the several suits still before the courts and in an unfinished state.

THE ELECTION OF OFFICERS.

It now becomes my duty under the Constitution to call for \$1.25 for the coming year (assessment \$1.00, and dues 25 cents) from each member. I therefore inclose a blank to be used for that purpose, and also a voting-blank. Fill up all the blanks, and send to the manager, with a postal note or money order for \$1.25. It must be sent by Aug. 1, 1887, or the vote will be lost.

CONCLUDING REMARKS.

I now submit my second annual report, with the hope that it will meet with the approbation of every member. If I have failed in any particular to act for the general interest of the pursuit of bee-keeping, it has been unintentional—that having been my only aim. I am now both ready and willing to transfer the office to my successor as soon as such is elected. Fraternally, THOMAS G. NEWMAN, General Manager.

Every bee-keeper having any interests at stake, who would secure the benefits of the Union, ought surely to become a member. Remember, "it will defend only its members who became such before any lawsuits were commenced against them."

MISHAPS IN INTRODUCING QUEENS.

ALSO SOMETHING ABOUT BEING POSITIVE, WHEN YOU MAY BE MISTAKEN.

I PRESUME that every one who rears queens for sale has had more or less complaint that the queen sent was pure black with no Italian blood about her; and this oftentimes happens when the queen-breeder has no blacks in his apiary, or none that he knows of in the vicinity. In past years there have been some unkind words, and perhaps some unkind feelings, in regard to this very matter; and to illustrate how easy it is to be mistaken we give the following from a friend to whom we sent a queen May 16. A little over a month afterward, you will notice, we received the following letter:

Friend Root:

I must say that the untested queen you sent me in May last was a black queen instead of an Italian; and if you don't believe it, you send me an untested queen at your expense, and I will send this one to you, and you can see for yourself, for I know, for I have tried her. I think you ought to make some amendment on her; if not, I think I will send to some other place hereafter. P. J. LONG.

Selbyville, Del., June 25, 1887.

We replied, stating that we thought it impossible that the queen he received had no Italian blood about her at all, and suggested that the queen we sent him was lost, and that one already in the hive, or that got in by some outside mishap, was in her place. Some time after, we received the following apology and acknowledgment of his mistake:

I was mistaken about that queen, I suppose, but she is not in the stand that I put her in. There is a black one in there, but I have noticed all of the stands, and found in one of them some Italians, and I suppose she has left the stand that I put her in and got into another one, from the looks of the bees. There are about a fifth or sixth of them Italians, and I think that she is in there with the black queen, by the looks of the bees. I will beg to be excused for writing what I did to you, for I would not have done it for twice the worth of the queen, if I had known it; but by a black queen being in there I thought you perhaps had got hold of a black one instead of Italian, by not noticing close. I don't want you to think that I was trying to cheat you out of a queen, for I don't mean to do any thing of the kind, for I want to deal with my fellow-men fair and square, if I possibly can. I am glad to find her in another stand; and more so, as I hope you won't think hard of my writing what I did, for I thought I was right. P. J. LONG.

Selbyville, Del., July 3, 1887.

Friend L., we didn't think you were trying to cheat us, for it is not likely that even a bad man would undertake to get another queen in such a way; but we did think you were a little hasty and a little more positive than need be. When things of this kind come up, we all need to go slow, and to have much charity for our fellow-men—the kind of charity that thinketh no evil; and this is what I need every day and every hour.

WHAT TO DO, AND HOW TO BE HAPPY WHILE DOING IT.

Continued from Feb. 15.

CHAPTER XXXVII.

While the earth remaineth, seedtime and harvest, and cold and heat, and summer and winter, and day and night shall not cease.—GEN. 8: 22.

After writing the last chapter of my book I decided that I wanted a little more experience in several lines of the work before going further. The principal point I have been trying to get before my readers is, that those who are out of employment can find plenty to do close by their homes, and that they may, if they choose, also find happiness in doing it. My wife suggests, however, that inasmuch as people do not all have tastes alike, it is doubtless true that not many men find the enjoyment and happiness in market gardening that I do, and no doubt she is correct; but it seems to me that almost any individual who has been for some time without work, and especially if he has seen his family suffer for the necessities of life, may be pretty sure to enjoy that which gives him something to do. It is true, however, that one can not expect to attain the greatest success in any work where his heart is not in it.

The past six months has been an excellent time for every thing pertaining to the work I have been mapping out in the former pages of this book. The trouble about low prices has seemed to vanish—at least in the locality of Medina; and from the market reports I judge it is to a certain extent true throughout the country in general. Good products command excellent prices everywhere, and I have not heard of a glut from stagnation in any line of produce in the way of vegetables or small fruits. Even the friends in the South, away down in Florida, seem to be getting satisfactory prices for almost all they have to sell. The greatest drawback, or hindrance, to the matter here, seems to be in being right up to the market, in crowding every product ahead as fast as it can go—that is, in getting these things ready just about the time people begin to want them. Last spring was not nearly as favorable here as it has been in former years for early gardening. Severe freezes came so much later than usual that much of our stuff was spoiled in spite of the precautions we took. A fierce wind, with a zero freeze, made havoc with our sashes, mats, cloth frames, etc.; and this is one great trouble with the frames covered with cloth instead of glass. Unless the frames are

fastened down very securely, the wind takes them and sometimes carries them long distances; and when this occurs during a severe freeze it is disastrous to the contents of the cold frames. At one time a cloth-covered frame was blown or whirled over on the greenhouse, breaking quite a little glass there. It is true, we may have weeks and months when they keep their places perfectly, and every thing seems to be working nicely; but a windy time comes, and the owner is almost tempted to wish he had never heard of cheap cloth frames instead of glass sash. Glass sash lie safely where you put them, providing they are not left in such a way that the wind gets under them and throws them over. The cloth has, however, so many advantages besides cheapness, that I have been thinking it would pay to have some arrangement to hold the frames in place. Last spring we succeeded in having an abundance of nice lettuce all through February, March, April, May, and even June; but just now, however, toward the latter part of July we find ourselves short. Lettuce sells now in Medina pretty fairly during every month of the year. In February, March, and April, we find no difficulty in getting 40 cts. a pound. In May it went down to 20 cts.; in June, 10 cts.; and now in July it sells at 5 cts. I suppose you know, however, that it pays an excellent profit at even 5 cts., if properly managed.

During the winter months, when there was but little to be carried on the wagon, one of our enterprising boys decided there was no use of having more than one person in charge of the wagon; and he declared he could sell almost as much stuff alone by himself, without having even a boy along. We have a big stout horse—one that is equal to any thing in the way of bad roads, but a horse that will stand anywhere you leave him, and as long as you want him to stand. Such a horse is an acquisition for a market-wagon. This young man also did all his loading up and preparing his stuff, or pretty nearly all, during the afternoon; then he was ready to start out the next morning, feeling sure that every thing was just as he placed it the night before; and where there were two on the wagon this could not well

be. When sleighing was good we procured a pair of runners that slipped on to the wagon in place of the wheels, and with this arrangement he found he could get around so rapidly as to meet almost all of his customers before any of his vegetables had time to freeze, even with moderate protection. When garden-stuff began to get more plentiful I thought he would need more help; but he was interested in seeing how long he could get along without the boy, and I believe he kept it up until the receipts from the wagon began to be about fifteen or twenty dollars a day. During strawberry time, however, when the receipts ran up one day to a little over \$32.00, he decided he needed a boy to help handle the stuff. Of course, he had a little more wages, as an encouragement to take charge of the whole institution. I used to estimate that it required about one-fourth of the value of garden-stuff to get it converted into cash. During this last spring, however, with the arrangement I have mentioned, the expense was something like this: Horse and wagon half a day, 70 cts.; man to go with it half a day, 80 cts.; total, \$1.50. Now, if we sold \$15.00 worth of goods during the forenoon, the cost of selling was only ten per cent; but we have not been able to keep the expense of selling as low as this much of the time.

Now, in regard to getting the stuff on the market when none is to be had elsewhere, so we can have the monopoly: In the latter part of the winter we had the only celery that was in Medina. This same young man gave me an agreeable surprise by telling me he could get 40 cts. a pound for all the celery we had left. There was none to be had elsewhere, and we have a few customers who will pay almost any price to get such delicacies in the winter time. In the same way we got 40 cts. a pound for our choice lettuce. I suppose the friends who have been through a similar experience know what a pleasant feeling it is to find you are going to get enough for your product to pay for all the trouble and bother, including bad luck and reverses. When prices are low it is always well to do the best you can, and *try* to make both ends meet. It certainly is not very pleasant to sit down and figure up that you have paid out more money in securing a crop than you can get for it at market prices. But we often have to meet this state of affairs—at least we do now and then. In such cases we ought to look over the ground carefully and see whether our crop may not be put away so as to be kept

until the glut in the market is over. We managed to house our celery so that most of it kept very nicely; but the expense of putting the crop away (during a snowstorm), the boards required to cover the crop, and the expense of banking it to keep out the frost, cost so much that I felt a good deal disheartened. I had not expected to get over 15 or 20 cts. a pound for it; but when Mr. Weed sold it for *forty* cts., then came the agreeable feeling that we could go to work to improve on our plans another season, with the assurance that we need not be afraid to invest some money in doing it well. I do like to do any thing well that I undertake. It was the same way with the lettuce. I discovered that I could safely make a nice little greenhouse in a good sunny exposure, for the sole purpose of growing *lettuce alone*, and nothing else.

In regard to outdoor crops I have been agreeably pleased to discover that we need not be afraid to go to the expense of thorough underdraining, manuring, and even ridging the ground up in the way we have, so as to have it dry enough to work in the spring. After the last severe freeze in April I decided it would be safe to at least try a good many of the hardier vegetables in the open ground, if I could get a piece of ground thoroughly prepared. The trouble was, it was all too wet when the frost got out. The most promising piece of ground was where celery had been last year, and the ground was left in high ridges during the winter. These ridges were mellow, and would work nicely when every thing else was wet and sticky. I went over the ground with a potato-fork, and tried it every forenoon and every afternoon, to find the very earliest hour when it would do to put heavy horses on to it; and, by the way, we can't expect to do very much on outdoor crops by spading up by hand. I have tried it some; but a team with improved machinery does so much more, it seems as if we had better wait a little, until the ground gets so that horses can go on it. This celery ground had been manured the summer before, so heavily that the celery was almost burned by the quantities of stable manure piled on to it. We plowed the ridges down, harrowed it, then worked in a little more of the very nicest manure we could get, and the ground was ready for our crops. A storm was coming on, and there was but little time. This season we have a grain-drill to sow our seeds with instead of doing it by hand. The grain-drill was brought out hastily, and a

part of the tubes were stopped up with wooden blocks, so that we could sow peas in a double row, then a space three feet, and then another double row, letting the phosphate attachment sow phosphate all over the ground. It took perhaps fifteen minutes to sow the peas, as above. Had we done it the old way by hand, the ground would need marking out with some sort of furrower; then we should have to sow our phosphate in the furrow, and sprinkle in the peas, either by hand or by some sort of hand-drill; then they must be covered over with a horse or by hand. The grain-drill did it all in these few minutes, and covered the seed perfectly. Before the drill was put away in the tool-shed, however, I sowed two double rows of spinach the same way we sowed our peas; then a couple of rows of Eclipse beets, and the machine was ready to go in under cover before the storm came. It seems to me I never had any piece of work so satisfactorily and quickly done as it sowed the beets and spinach. All the time occupied was in letting the team walk from one end of the field to the other. I left spaces between the beets, for early cabbage. These we managed to get in, the same day. They were our best plants, from the cold frames, and wintered outdoors, so of course they could stand a freeze. The freeze came, and the cabbages looked for a good while as though they would never do any thing. They stood there; they did not die, it is true, but they did not seem to grow a bit. The weather was so cold that the beets and peas were so slow in starting that I began to be afraid that they were not going to start, but they did. The spinach, however, came up the first of any thing. It was too cold for any kind of weeds, so the hardy spinach had the full use of the ground. By and by the cabbages got started; and after a while the beets began to come up quite thickly. The spinach never received any hoeing or weeding whatever. Before weeds had a chance to make their appearance, the leaves covered the ground; and when the vegetable was worth \$2.00 a barrel at wholesale, we could easily get a barrel of extra nice from a rod of row.

Now, very likely many of you know nothing about spinach. When we first put it on our lunch-room table a great many would not take it at all—said they didn't like "greens." I explained to them that spinach was not greens at all—that it is a delicious vegetable more like asparagus. Finally they got to tasting it, and pretty soon

spinach was in big demand. Let me remind the housewives not to cook it as greens. Cook it as you do asparagus, and it will pretty soon go off fast enough. It seemed for a time as if our town could not get enough of it; and after the plant began to send up seed-stalks a yard high, we sold it for greens even then. These two rows, however, were too much for our Medina market. It could not be all disposed of before it would probably get too old and hard for use. As it was a new vegetable to us, however, we did not know just when it would cease to be edible; but as there was more than our town could consume, it began to be a question what we should do with it. I remembered hearing about a kind of cabbage that grew so fast that one head would support a cow—that is, as many leaves would grow over night as she could eat during the day; and when I saw our Jersey cow looking wishfully at the beautiful dark-green rows of spinach, I pulled her an armful to let her taste them; and from that day forward she had spinach to her heart's content. In fact, she preferred spinach to any thing else that could be offered her, and it seemed almost impossible to give her more than she could dispose of. Did it affect the milk? Not at all, until the plants had gone so far in perfecting seed-stalks that they were slightly bitter, then the milk began to taste of it. Now, this plant made this luxuriant growth almost before any thing else began to look green; and I hereby give notice to the agricultural papers, and to farmers in general, that spinach may be raised for cows before you can raise any thing else I know of, unless, indeed, it is rye, and I am sure that spinach will go away ahead of rye in the amount of foliage it produces. If it happens to be worth two or three dollars a barrel in the market, why, of course you would not think of giving it to your cows. The books tell us it can be wintered over just as well as wheat or rye. I have never succeeded in doing it, however; but I am going to try harder again this fall and winter, and I think I shall succeed. After we had used and sold all we could of those two rows, I kept the cow on it for quite a long time, and then there was considerable still left to go to seed. When the seed got brown we cut it with a cradle, and it is now stored away on the barn floor, dry enough to thrash, and fan out with a fanning-mill, so I have my own seed for next year. There is just one thing about this great crop of spinach that I think it may perhaps be well to

mention. Joseph Harris, of the *American Agriculturist*, has been writing a great deal about nitrate of soda, especially its property of furnishing nitrogen very early in the spring, much cheaper than we can get from stable manure. I bought a bagful; and as some of the papers said it was especially suited for spinach, I put a pretty good-sized sprinkling on just one-half of the two rows (when the plants were small) and put it on to the poorest end of the piece of ground. Well, I watched and watched to see any effect produced, until I concluded it was not going to do any good at all upon our soil, and forgot about it; but when I began feeding it to the cow I noticed the spinach was a great deal larger and stronger where the nitrate of soda was, although, as I said before, this end of the field had always been much the poorest ground.

Well, about the time spinach failed we began to get nice beets from that patch. They came up very thickly, and we did not thin them at all, proposing to use the thinnings for beet-greens. From those two rows of beets we have sold beets all over town—have supplied the lunch-room, and there are a good many there yet. The beets were put in between the cabbages, so the ground they grew up on cost nothing, in one sense; in another sense it did cost, because we tramped the ground down so hard around the cabbages in going for the beets in all kinds of weather. On this account the cabbages have not done as well as they did last season; but last season we thought they were doing great things when we succeeded in getting 3 cents a pound for them. This year, however, Mr. Weed started them at 5 cents a pound, and they brought it without any trouble, and we are even to-day (July 19th) getting 5 cents a pound for every cabbage as fast as it makes any kind of firm head, and we don't have enough to supply the wagon.

The peas did beautifully. They were half Landreth's Extra Early, and half American Wonder. The American Wonder was only about three days later, and a great deal better in quality. We got 40 cents a peck, for most of the peas; but the crop was so great that at one time we feared we should not be able to dispose of all of it in Medina. One week later, however, we discovered that our peas were gone just as we had got a big trade started in them; and the worst of it was, we hadn't a pea anywhere else on our ten-acre farm that was yet in blossom. A year ago we had too many peas and cabbages in July,

so I concluded this season not to plant so extensively, and there is where I made a blunder. The quantity we had last year would have been exactly right for this, for our market has improved so much. Last year people were discussing my right to raise garden-stuff. This season, however, they have all given it up—every one of them, and everybody seemed by actual consent and good nature to decide I was the chap to raise garden-stuff, and therefore they would not raise any at all. I am ashamed of my lack of faith. Faith in what, do you ask? Why, faith in good gardening and good steady work in any line of agricultural industry. It is impossible for me to say just now how much money we receive from the product of the half-acre I have been speaking of; but it would be a large sum. A crop of nice cabbages how stands where the peas stood. The beets and cabbages are pretty much gone; but even yet they give a good daily income. We are waiting for them all to mature before putting another crop in their place. I hardly believe I shall plant beets between cabbages again. The beets do not get out of the way soon enough. I presume I put more manure on that half-acre than I ever put on any other piece of ground before; but now that we have got it up to a high state of cultivation, it is only just fun to raise a crop on it. The last cabbages were planted in a dry time, but they took right hold and grew without any rain, almost as if rich ground like that didn't need any rain. The soil has been kept light and soft by constant stirring, keeping what some of the agricultural papers call a "dust blanket" all around the plants. This dust blanket serves as a mulch; and when we get just a little shower of rain, the dust blanket takes it all up, much as a sponge would, while hard lumpy soil would let the water all run off and be lost.

MAKING REPEATED PLANTINGS.

It seems hard for us to remember that it costs but little to put in the seed for early stuff, even if it is killed by frost, or does not germinate. You see, it all depends on having things on the market first; and it is so natural to procrastinate, or delay, that it is almost impossible to avoid falling into the common way of doing things the world over. The man who has his vegetables and fruits on the market first, takes the big prices. Now, there is not any need of saying, "It is no use—somebody else will get ahead of me;" for season after season we see it demonstrated right before our eyes, that not

only days but weeks of beautiful weather come and go, unimproved. As an illustration, during the winter I read up the matter of early cucumbers, in our books and agricultural papers, until I was impatient for the time to come when I could start some in cold frames; and several hundred squash-boxes, such as are shown in Chapter XXIV., were made up in anticipation of the time when they would be used for squashes, cucumbers, etc. Well, how many do you suppose we used for the above purpose? Not one. And how many hills of cucumbers do you suppose we put in our cold frames, where they could be protected from frost when a cold night came? Not one. We started some cucumbers in the greenhouse, it is true, and transplanted them outdoors as soon as we could get the ground suitably prepared; but by this time there proved to be no further need of the boxes to keep off frost, and no further need of the sash on cold frames. We transplanted our cucumbers from the greenhouse into the cold frames, intending to put on the sash; but there was not a night cold enough to need the sash after we got around to doing it. Well, at the same time we transplanted these cucumbers we put a few seeds in the open ground right beside them. This open ground was in a cold frame, and very rich with manure. The weather was so favorable that the seeds came up almost as if by magic, and this, too, without any sash over them, remember. I didn't put on the sash, because we had a succession of warm showers; and the seeds that were planted beside the transplanted plants for cucumbers, gave cucumbers exactly the same time as the latter, although the plants in the greenhouse had three or four large leaves on them when set out, and some of them even had a blossom or two. But, my friends, even slipshod management like this paid a big profit. A cold frame the size of six sash gave a peck of cucumbers a day in July, that sold for 5 cents each, or by the pound at a uniform price of 10 cents per pound, which I think is by far the better way. Even at this date, all the cucumbers we get from the open field bring 10 cents per pound right along; and in June they sold readily at 20 cents a pound, in considerable numbers too. Of course, the market may be overstocked in a town the size of ours; and while they take from a half to a whole bushel of cucumbers a day, and pay good prices, if we were to produce twice that quantity we should very likely overstock the market, and in a little

time people would get tired of them. To avoid this you must have a variety. When people tire of one thing, give them something else. Something new is constantly wanted; and when it starts out you can get excellent prices for it. Our first green corn, put on the market July 18, brought 20 cents per dozen. It is Ford's Early corn; and although the ears are very small, the quality is so good that people don't mind paying a good price for the first. By our blunder in not having a crop of new peas for a week or two, our people got quite hungry for them; and when we commenced on the Stratagems this week they went off at 40 cents a peck quite readily, even when two or three bushels per day were put on the wagon.

RAWSON'S SQUASH-BOXES, AND DO THEY PAY?

Now in regard to getting the ground ready, and *trying* a few seeds, even before we have reason to expect they will amount to any thing. We did this with the peas pretty well. We sowed our first in the latter part of February. We fixed the ground the best we knew how, and manured it lavishly; and although they started during March they did not get ahead of some sowed a month later, and both the February sowing and the March sowing produced peas fit for the table only three or four days before those put in with a grain-drill in April; so you see this year not much was gained by sowing them very early. With cucumbers, however, we did a very nice thing in sowing a long row on the creek-bottom ground fully two weeks before anybody would suppose it would answer. The weather was so favorable they did not need the squash-boxes at all, as I have told you; that is, they did not need them on account of frost. They did need them, however, on account of bugs. One morning in May, one of my men told me our squashes would have to be taken care of or the bugs would destroy them. The wagon was not ready just then to bring the boxes out to the field, and so I didn't attend to it right away. I had been through the patch in the morning, and didn't see any bugs, and therefore I began to conclude that may be we shouldn't need to bring the boxes out at all. I happened to pass through the vines, however, about ten o'clock. Imagine my surprise to find swarms of striped yellow bugs all over the vines; and to my great surprise, some of my beautiful squashes, with the first leaf almost as large as your hand (providing your hand is a very small one) literally torn to bits by those voracious

insects. I had heard that boxes without any thing over the top would keep off the bugs, and half a dozen boys were sent for the boxes in a hurry, I tell you. The bugs were scared off, the boxes placed carefully over the vines, and the soft mellow dirt banked around the lower edges to make them tight. The bugs were foiled for three or four hours. The weather was too hot to put in the glass, so we tacked pieces of mosquito-netting over the tops. I didn't discover how much harm the bugs were doing again until after sun-down; but I saw then there wasn't a moment to lose. We couldn't even wait till morning. I found some of the women still in the book-bindery at the factory. I asked them to cut me 200 pieces of mosquito-bar as quickly as possible. Then I called the children, aged respectively 14, 8, and 4, got a pocketful of small tacks, and two or three three-cent hammers. On the way to the field we met one of our eldest daughter's schoolmates, a young miss thirteen or fourteen, and I secured her services. When we got down by the carp-pond a small boy came up with the oft-repeated question,—

"Mr. Root, can't you give me a job?"

"Yes, sir," said I, "if you will go right to work now."

He replied that he had not intended to work until morning, but if I were very particular he guessed he would help. This boy was about six years old. Caddie's cousin Mabel, also eight years old, made up the number, and we seven had the mosquito-netting put on nicely before it was dark. Besides chasing the bugs, we stopped up the crevices below again. It was Saturday night was one reason why I hurried; but it saved our Hubbard squashes and Boston marrow squashes and cucumbers. The bugs swarmed all over the boxes, and looked through the mosquito-netting, and probably lamented that they were foiled. We left part of the vines without the covering, to see what they would do. About half of

them survived until Monday morning, and then we made another disappointing discovery. The yellow bugs, after working for two days at the problem, discovered they could get through the mosquito-netting by dint of hard kicking, and Monday they could be seen on almost every box, half way through the netting, kicking their heels up in the air. They didn't get in, however, to do very much harm, and the rest of the vines were covered with boxes protected by *grenadine*, such as we use for bee-veils. This fabric costs a little more per yard, but it is absolutely secure. The vines under these boxes covered with *grenadine* were the handsomest I ever saw in all my life. There was not a speck or blemish on the bright-green leaves; and, oh how they did grow! In a little time they raised up the netting so that it looked as if they might raise the wooden boxes too, if we didn't give them room, and in eight or ten days the bugs were gone. We tumbled off the boxes, put them into the wagon, and stowed them away in the tool-house; but they had paid their cost in satisfaction if not in dollars and cents. We have not sold the squashes yet, so we can not tell how they will come out; but there is a lot of them now, as big as goose-eggs.

There is a point I wish to make right here in regard to fighting bugs and insect enemies. I do love to have something that is absolute and certain. Where we use Paris green, slug-shot, and most other poisons, the matter is imperfect and uncertain. The bugs are mostly killed; but if a rain comes we have to go over the same thing again, and sometimes the poison does not seem to work. It is true, it is some trouble to put the squash-boxes on and take them off again; but it is absolute and sure; and I believe that next season we will use these same boxes for our early potatoes, instead of having children pick the bugs off by hand, as we have done during this past season.

CHAPTER XXXVIII.

TILTH VERSUS MANURE.

He that tilleth his land shall have plenty of bread.—PROV. 28: 19.

I have been making a good many experiments during the past few months, to ascertain how far tilth may take the place of manure. In the previous chapter I spoke of the dust blanket to mulch plants, as a rem-

edy for drought. Now, we can't have a dust blanket unless we have the dust; and the only way to get the dust is to make the soil so fine that it works like dust. It may be damp dust, but it should be thoroughly fined

up, to get the best results. The Acme harrow, figured in Chapter XVI., is a splendid machine, in connection with the roller, to get this dust; but it has never worked deep enough to really suit me, especially in stub-born clay soils. This spring and summer we have been using a disk harrow that pleases me much.

This machine can be made to cut down so deeply, by adjusting the position of the disks, that it almost plows the ground; in fact, after digging your early potatoes it will do a very good job of plowing and harrowing, if you pass it over the ground repeatedly, and cross it in different directions. It not only cuts up the lumps, but it scrapes them as you would scrape an apple with the point of a case-knife. It also pushes sods, vines, litter, etc., down deep into the ground, instead of tearing them up. It, however, leaves the surface much more uneven than the Acme harrow, and on this account I prefer to follow it with the Acme or Thomas smoothing-harrow, shown in Chapter XVIII. Some of you may smile at the idea of having so many tools for a farm of ten acres; but, my friend, if tools enable you to get double the crop you would have without them, or if you do the work in half the time you could do it with ordinary tools, they will eventually prove to be a saving.

I want to tell you of a little experiment I made, to show what tilth will do. We had some musk-melons on the creek-bottom ground, that were so nearly used up by the bugs and drought that I had almost decided to plow them up and put in some other crop. We didn't have enough squash-boxes to go over the musk-melons, and they were, so to speak, left out in the cold. A great many of them were used up entirely, and the rest looked as if it were utterly impossible they should be of any use. I thought, before plowing them up, I would experiment on them some, so I picked out a nice steel rake.

The handle had been broken off, so it was not longer than an ordinary hoe-handle. The rake had been used so much that the teeth were bright and sharp. Well, with this rake I went around several of the melon-plants, and scratched away the surface dirt until I got down to where I could see the white roots coming out on the stem of the plant. This operation of scratching the dirt away with that sharp-toothed rake fined the ground up almost like dust. I then fined up the earth for pretty nearly a yard in each direction around the plant. When I had a sufficient quantity I banked

it up around the plant, clear up to the leaves, and I made the bank flat on top, instead of sharp, the way a good many hill up potatoes. This gave the plant a dust blanket three or four inches in depth, and perhaps three or four feet across the level top.

A point comes in right here that I wish to consider, in making plants grow. On ordinary ground we do not have more than from four to six inches of good rich mellow soil. If you plow down deeper than six inches you turn up lumps of hard subsoil that will spoil your whole crop, as many of you have learned by past experience. Now, instead of plowing down six inches more to get a depth of soil a foot, suppose you scrape off this surface soil from a part of the ground, so as to make it double depth on another part; you then have ten or twelve inches of fine mellow *fertile* soil; and this will give you a good big crop of almost any thing. I first noticed it in scraping off the surface soil where we wanted a road at one end of our long piece of ground. Where I doubled the dust blanket I could raise magnificent cauliflower, and great whopping potatoes, with a good many in a hill; but with a single thickness of dust blanket, the results were only ordinary. Well, now, around my melon-plants I had a double thickness of dust blanket. The melons were six feet apart, and it was no trouble at all to get fine dirt enough to fix each plant as I have described. What was the effect? Why, those poor, miserable, starved, sickly melon-plants of a month or six weeks ago are now the finest I ever owned in my life. I didn't know before that a poor, miserable, sickly plant could be transformed by tilth alone. When I was satisfied with the way it worked I cultivated the ground between the melon-plants until it was about as fine as I could get it with a horse, then I got one of my boys, who would do exactly as I told him, and not according to his own notion of things. I told him I wanted all of our melons, squashes, and cucumbers fixed like the sample I did while he was watching. Now, he, like all the rest, was so prone to just pile up the dirt in a sharp hill that it was some little time before I got him to do as I did; and, by the way, there are a good many boys and men who absolutely will not place the soil so as to make a broad hill around the plant, to catch the rain. They have so long been accustomed to piling the dirt up into a sharp-pointed cone that they won't do it in any other way. Well, this matter of scraping the dirt away with a

rake until you begin to strike the roots is another point that I can't get boys and men to do. They will start out all right; but when I come back to examine the plants, and try to put my fingers down among the roots, I find the dirt so hard that it is very plain the rake-teeth never went down there at all. This is the great secret of making things grow, however. If the ground is loose and porous, the air gets down around the roots, and the soil keeps very much damper than if it were packed hard and stubborn. When rain comes, your dust blanket of several inches in thickness soaks up the water like a sponge, and holds it, even during a pretty long drought; while a soil that had not been worked up into dust would neither catch nor hold hardly any of the water that fell.

TRANSPLANTING IN JULY AND AUGUST.

In spite of all that has been said on this subject, it seems there is no end to the time and money wasted in this simple operation. During a rainy time, when it rains every afternoon, or almost every night, almost any kind of plant will grow if a little dirt is over the roots in any sort of shape; but where you want to put out cabbage and celery plants in July or August, and during a time of drought, there must be different management. In the first place, you want transplanted plants. A cabbage-plant or celery-plant grown in the seed-bed, with the soil ever so good, and with the plants scattered over plenty of ground, is pretty sure to send down a single tap-root, with a few roots running out each way. When they are pulled up, the little roots snap off, and the tap-root breaks off, a great portion of it. By digging them out with a spading-fork you can get more of the roots; but even then the plant is not to be compared to one that has been transplanted according to the directions in the fore part of these writings. About six weeks ago we had some very large, fine-looking celery-plants standing in the seed-bed. They were almost too large to transplant, so I decided to put them into the rows in the field, just as they were. We had plenty of rain; but the greater part of them died. At the same time, we put in one or two rows of transplanted plants. These had great bunches of roots, something like a small brush-heap; and when the plants were pulled up, the ground being properly wetted beforehand, this mass of roots brought along with it a great lot of the rich soil of the plant-bed. Well, these trans-

planted plants are to-day great stout stalks of celery that would do very well to put on the table, while those taken from the seed-bed are spindling and feeble in comparison.

Now, when you get your transplanted plants with a great strong mass of fibrous roots to each plant, do not, under any circumstances, pull them up so as to tear the roots off, nor let any man or boy do it. If you don't watch them carefully they surely will; and it does not seem to make much difference how many times they have been cautioned and talked to. Before trying to remove any plant, soak the ground thoroughly with water, no matter if it has been raining within an hour. Soak the ground until it is so soft that every thing is in a mush. If possible, soak the ground two or three hours before you wish to remove the plants, then soak it again just as you take it up.

Few people have any comprehension of the amount of water that a small spot of ground will take up; and if you want to get your plants up nicely you must pour on water at intervals until the plants will come up without the snapping or breaking of a single fibrous root. As the plants are pulled up, lay them down gently in a market basket stood on end. When you carry them to the field don't carry the basket by the handle, but take hold of the upper end of it. If a boy drops plants, don't let him pick them up by the tops and drop them into the furrow. Insist that he handle them by the *roots*, and keep every particle of wet dirt adhering to them all he possibly can. Don't be satisfied by once telling him, for he will soon get tired, and begin to pull them out of the basket by the tops, letting the dirt slip off or rattle off. Keep your eye on your boy and on your plants. Set them in place in the furrow; press the soft earth about them; and if the weather is dry, firm the dirt around each plant, by setting your foot on each side of it. You can do this after you have got them all in the ground. Now finish off with your dust blanket, by pulling up some soft fine dirt around each plant, with a rake. If the ground is moist from a recent rain, you can omit the firming. Plants set out in this manner will grow right along; and instead of being discouraged and hindered they only seem to rejoice at having plenty of room and plenty of daylight all around them, compared with their crowded situation in the plant-bed from which they had just been removed.

To be continued.

PROF. COOK'S CELLAR FOR WINTERING BEES.

DR. C. C. MILLER'S CRITICISMS.

PROF. COOK'S ideal house for the apiary is equaled, I venture to say, by few in actual existence. To the many who may contemplate building, however, the right plan is of so much importance that his plans deserve what I know he desires—the closest discussion.

Nothing is said about the number of colonies for which provision is to be made—a matter that can not be ignored. It is better to have too much than too little room; and one is hardly sure, at any time, to what number he may increase. I should think Prof. Cook's plan is ample for 500 colonies, except in the matter of cellar room. I question whether his house could be built in this locality for \$500. Mine is 18 x 24, three-fifths the size of his, less expensively furnished, and I think it cost about \$400.

I should like the chamber higher than 6 ft. at the lowest part. The cost for two feet more in height is little, and it often happens that one wants to stack up things as high or higher than he can reach; 16-foot posts will make each story higher.

The timbers for the lower floor should be made of extra strength, if honey is to be stored there; and this reminds me that, in such a case, 30 x 24 may not be large enough for 500 colonies. My honey is stored in a separate building, which makes a difference. I suspect it would be better to have all in one building.

Does it pay to give up two fifths of the cellar room for the sake of having that outside room? Of course, if there are bees enough only to fill the room 18 x 24, it may be better to put in a partition; but even in that case I believe I would rather have the one room 30 x 24. I have an impression, from no little experience and observation, that the fewer colonies in a cellar, or the larger the cellar for a given number of bees, the better they will winter.

His idea of having the cellar entirely under ground is capital. If the lay of the land does not make it so, it can be made so by heavy banking.

He says the cellar should be "grouted below and plastered above, with a double floor grouted between." If by being "grouted below" he means a floor of cement, or grout, I raise question. I have one cellar room with a cement bottom, and I have an impression that the earth floors do a little toward purifying the air. The reverse, however, may be the case. How is that, professor? And just how is the "double floor grouted between" made? My shop cellar is not yet plastered overhead. Is there anything I can do, better than to have common lath and plaster for a ceiling?

If there is any danger from rats, it is a matter of little cost and much importance to have the cellar wall extend a foot below the level of the floor. Dig a trench a foot deep, around the cellar, under where the wall is to be placed, and fill it up with small stones and grout. No rat will ever undermine this. A rat does not dig down to get under a wall, but gets inside and digs out.

Four-inch glazed tile is mentioned for a sub-ventilation pipe in the text; and in the reference to figure it is called six-inch. Which is right? Glazed tile is much more expensive than unglazed, but perhaps its greater durability may make the glazed preferable. If four-inch tile is used, little or nothing is gained by having the drain more than 100

feet long. If there is any point at which I consider Prof. Cook an unsafe adviser, it is at the point of ventilation. Although I can not give positive proof for my position, I have had a good deal of presumptive evidence, based on a good deal of experience, that it is well to have a cellar thoroughly ventilated. As he says in remarks upon diagram, I prefer a ten-inch tile. The difference in cost is not great between that and smaller tile; and if at any time the ten-inch tile admits air too rapidly it can be lessened to any desired extent. The ideal cellar for wintering bees will have a larger area for entrance than for exit of air, the walls at all points being as nearly as possible air-tight.

I don't see how emptying the cistern will do much toward cooling the cellar. Little or no rain will enter it after freezing weather, and the water will acquire nearly the same temperature as the cellar, so I don't feel so sanguine that "we have an arrangement by which we can control the temperature perfectly from October to May." I do have faith that some day some one will get sub-ventilation to such a point that, through the whole winter, sufficient air of the right temperature shall pass through a cellar to control the temperature of the cellar.

I wouldn't use a wheelbarrow to take bees in or out of a cellar. I object, even, to any one stepping heavily when carrying them. On taking in, shaking up makes them more uneasy; and on taking out, it makes them fly out before being placed on the stand.

I am not sure that I like the professor's southeast room for comb honey and office. For wintering comb honey it might be good; but it is not the best place for ripening honey in summer and fall. As to an office, I am afraid I shouldn't use it much if I had it. Until the last year I never had so much as a desk, and even now my office is as likely as not to be the dining-table. A literary man, or a man in Prof. Cook's position, may need an office; but there isn't much chance for office work in bee-keeping.

The diagram shows the double doors opening at opposite sides, thus:

I think mine are more convenient, opening at the same side of the doorway, but hinged on different sides of the jamb.

It might be economy of room, and a little more convenient, if the stairway were close to the outside door.

C. C. MILLER.

Marengo, Ill.

Friend M., since you mention it I want to suggest that the floor on which the honey is to stand should be made exceedingly stout and strong. Three or four times in my experience I have seen floors seriously injured by the honey that has been piled on them. Our extracted honey rests directly on the ground, in the basement. I presume there would be an objection to placing comb honey this way; but please remember that the floor that is to hold the honey must be made to stand the effect of a tremendous weight, as well as the ravages of time. I would have good stone underpinning, and timbers that will not rot or break. I would also say, by all means have the wintering-cellar under ground. Sawdust walls do very well

until we have a freeze that is unusual in severity and duration; then a cellar is away ahead. By all means, fence out rats. I also agree with you in regard to ample ventilation. Have the sub-earth ventilator large, or two of them. When the air is pure, the bees are quiet. When it smells close and bad, then is the time they begin to get up a roar.—Friend M., while reading your objections to a wheelbarrow I could not help wondering if you were not thinking of that old-fashioned home-made one of yours. Please bear in mind that the new light wheelbarrows we have for sale do not wake up all the babies in the neighborhood when you are wheeling a bee-hive. Put a coat of sawdust on the floor, and neither the stepping nor the barrow will give back any sound. May be your wife might have some different ideas in regard to having a desk in an office, in place of using a dining-table.

BLISTER-BEETLE LARVÆ ON BEES.

A WONDERFULLY STRANGE AND CURIOUS FOE.

THE insects sent by Mr. Hammond, Ellensburg Center, N. Y., are interesting, as this is the first time, so far as I know, that such insects have been reported as disturbing bees this side of California. By referring to my Bee-Keeper's Guide, p. 329 (10th to 14th thousand), there will be found an illustration of a similar insect, or possibly the same species, which was discovered by Mr. Rainbow, of Fall Brook, Cal. He says he found as many as seven of the insects on a single worker bee. Mr. Hammond says they make the bees uncomfortable, if we may judge by the actions of the latter, as "they try to rub the parasites off, and twist as though they itched and were trying to scratch themselves." There were three bees sent in a small tin box, and twelve of the parasites.

LARVA OF BLISTER-BEETLE, TAKEN FROM HONEY-BEE.

These insects are really the larvæ of some blister-beetle. As *Meloe Angusticollis* is a very common species in all our Northern States, it is not unlikely that this larva belongs to that species. This beetle, which is also illustrated in the Manual of the Apiary, page 329, is of a dark-blue color, has short wing-covers, and the gravid female has a very large abdomen, which should not astonish us when we remember that she may lay from 3000 to 4000 soft whitish cylindrical eggs. We have several species of blister-beetles, all of which, I believe, have vesicatory properties, and might be used as satisfactorily in medical practice as is the "Spanish fly"—more properly the Spanish beetle. The meloe beetles lay their numerous eggs in patches in the earth. The eggs hatch, and the young—the same

as those discovered by Mr. Hammond upon his bees—crawl upon some aster, goldenrod, etc., and wait for some bee to come along. As soon as a bee alights upon the plant they crawl upon it and so find a safe and easy transit to a hive, where it is said that they pass from the bees and subsist on eggs. As they seem to adhere to the bees so tenaciously and persistently, may it not be that they also feed upon pollen that has adhered to the bee? As their mouth parts are fitted for biting rather than piercing and sucking, we can hardly think that they do any very serious harm to the bees. This form of the insect, generally known as triungulin, was supposed by even so good a naturalist as Reaumur to be a louse. It is supposed that, once in the hive or in a bee-nest—Newport, as early as 1841, found these insects in the nest of anthophora, a wild bee—they live on eggs. Soon a second larval form appears, which is larger, but slow and awkward in its motions. Newport says this feeds upon the honey. It probably also feeds upon pollen, as honey alone could hardly supply its needs. Soon it changes again, when it looks like a pupa, though this soon transforms into a third larva, and then to true pupa, and last into the mature beetle.

Fabre denominated these curious changes hypermetamorphoses, to distinguish them from the usual transformations of insects. These changes were first described fully by Fabre in 1856.

The second and third larval conditions are quite degraded, and remind one of bot-fly maggots and other dipterous larvæ. The first, or pseudo-pupa, looks very much like a real pupa. As these insects have never been studied in full except in the nests of wild bees, it is a question of much interest whether they go through all their changes in the hive of our honey-bees, and whether they do live on eggs and honey as Newport and Fabre suggest, or whether they may not feed upon the pollen of the hive or the food of the larval bees, and possibly on the young or immature bees. These questions are very interesting ones, and their answer would satisfy Mr. Hammond's query as to the extent of harm they may do, and the probability of their spreading. The very fact that, as yet, they have never done serious harm, makes it probable that they will not do so. If Mr. Hammond will send me fifty or a hundred of these triungulins in a close tin box, with a few of the bees on which they are found, I will try hard to find out just what they will do.

A. J. COOK.

Agricultural College, July, 1887.

THE BEE-MARTIN.

HAS HE A MEANS OF ATTRACTING BEES?

SINCE it seems to be a universally admitted fact that the bee-martin is destructive to honey-bees, are you aware that he is provided with a natural means of attracting the unwary bee and other honey-gathering insects within his reach? Having heard this a few days ago for the first time, and being just the least bit skeptical—although we got our information from a reliable source—and observing a bee-martin innocently perched on the top branch of an apple-tree in our apiary, we determined to make a sacrifice of him in the interest of science, or, more properly speaking,

for the gratification of curiosity, and accordingly had our little boy dispatch him with his sling-shot. On examination we found it just as represented; to wit, that while on the wing, or not in quest of food, the back of his head is smooth, sleek, and black; but when he starts out for a meal he perches upon an exposed twig, sets his decoy, and waits for the lurement of prey. The decoy consists of a good imitation of a bright attractive little flower on the top of the head, in which white, lemon-yellow, and deep orange colors are beautifully blended, which the bird has the power of displaying at pleasure. It is the belief among old bee-hunters that he uses this to attract bees and other insects that gather honey from flowers, and is thus enabled to secure his meals without much exertion. It is a regular "won't you walk into my parlor?" game he plays, and his hospitality is about on a par with that of the spider.

The long-continued dry spell here has materially lessened this season's honey crop; in fact, it will be next to a complete failure, unless the fall flow should be unusually good. In our apiary the colonies have the lower frames all filled with honey, but thus far they have stored very little in the section boxes. They disposed of the drones some time ago, and are now apparently laying up stores for the coming winter.

We have aimed to keep our colonies strong and active; and hence, by destroying queen-cells, have prevented swarming to a great extent, having no desire to increase our present stock. We have the Carniolans from Germany; Italians, hybrids, and blacks; but for gentleness and docility in handling, the Carniolans take the palm by a large majority.

Taylorville, Ill., July 4, 1887.

J. F. HARNER.

ALSIKE AND ITS PECULIAR CHARACTERISTICS.

A POSSIBLE EXPLANATION FOR THE MISUNDERSTANDING BETWEEN FRIENDS MUTH AND CORY.

IN looking GLEANINGS over, my eyes struck Prof. Cook's article on alsike clover. I am surprised that any one should have any trouble in identifying it from red clover. Friend Cook is sound in his conclusions, but I think there is one point he does not fully reach. Alsike will germinate where common clover will; but if we have a dry spell after it comes up it is *quite apt* to die almost entirely, where the size and vigor of the red would carry it safely through. It does not sport. I have watched (supposing it to be a hybrid) for five years carefully, to find some variation of the set type, and have publicly offered \$50.00 for a cross between alsike and small red clover, but all to no purpose. In its root formation, alsike varies; and the tint or color of the blossoms ranges from *almost* clear white to *almost* red, but *never* reaches either extreme. Clover seed will remain in the soil for years, and then, under favorable conditions, germinate and grow. Has not alsike been sown on land where red-clover seed already existed, and the alsike germinated, and died of drought, while the greater size of seed, and the greater depth of root, enabled the red to survive, and thus cause the purchaser to suppose he has been supplied with the wrong kind of seed? This is no theory. It *has occurred* right here on my farm, and also with my neighbors.

C. M. GOODSPEED.

Thorn Hill, N. Y., July 11, 1887.

HEADS OF GRAIN FROM DIFFERENT FIELDS.

KIND WORDS IN REGARD TO THOMAS HORN.

FRIEND ROOT:—In the case of "Thomas Horn vs. duped customers," I think your proposition to settle his delinquencies a bad precedent, as there is certainly no just claim on you, that I can see. At the same time, I consider it a very generous offer on your part. If you are going to warrant and insure the honesty of advertisers in GLEANINGS, I think you will go under, unless you charge a premium extra. If you make reasonable search into the standing of each new advertiser before inserting his advertisement, I think it all in reason required of you. This is the second time, to my knowledge, that you have proposed to let yourself be mulcted on account of faithless advertisers. I would advise you to stop right here now, and insert, in large letters, at the head of advertisements, in front and back of GLEANINGS, that you will not hereafter pay any delinquencies of advertisers—that you take proper and reasonable care to find out their standing; and having done this much, you will no longer assure and defend.

C. GARWOOD.

Baltimore, Md., July 19, 1887.

Friend G., I am very much obliged to you indeed for your kind words and kind counsel. I know it is, in one sense, establishing something of a precedent; but in this case it seems pretty evident we were taken in by a bad, unprincipled man. For a long time I had so much charity for him that I believed he was simply unfortunate, or lacking in judgment. The evidence now is, that he is untruthful; and a man who will lie, will, as a general thing, steal, sooner or later. If it is true, then, that I unconsciously permitted a liar and thief to occupy our advertising pages, I feel somewhat responsible. These are hard words I am using, I know; and if they come to the eyes of Mr. Horn or his friends, and they show me I am mistaken, or too severe, I am ready and willing to take them back. If one of our advertisers should, by lack of judgment or the force of circumstances, make a business failure, I should not propose to pay his debts for him; but where I am satisfied I have let a bad man impose upon our readers, I feel better to shoulder the responsibility. I want to do what is right, and I have found it an excellent rule to make it a point to do a little *more* than what seems exactly right. In this way we make allowance for the selfishness there is in even the best of us.

TWO QUEENS IN A HIVE.

Last spring I bought a colony of hybrid bees from a neighbor. I removed the old queen, and inserted a queen-cell. In course of time I had a nice tested queen which I shipped to a customer. I then removed a queen that had her wing cut off, and introduced her in the colony from which I sold the queen. It was hard to get the bees to take her. After being caged about a week, I saw it would be safe to let her out, so I put a plug of the Good candy in the cage so they could eat her out, and closed up the hive. I took sick and didn't get to look after her for a couple of weeks, then I opened the hive.

The first frame I took out had a nice young queen on, which was laying, so I put her back, thinking they had killed the queen that was clipped. The other day I wanted an untested queen for a customer. I went to that hive, and commenced taking out the frames at one side. To my surprise, there was my queen with her wing cut. I took out the rest of the frames, and at the other side of the hive was the other queen, both laying right along. I have often had two queens in one hive, when the one was to be superseded on account of old age, but I consider this a rare occurrence; for the queen that has her wing cut, that is in the hive now, is only one year old—a good layer, and as fine a queen as you want to see, and there are no signs of their superseding her.

C. M. HICKS.

Fairview, Md., July 20, 1887.

The fact you relate is not so very uncommon, especially when the second queen was raised in the hive with the old queen. Only recently we had a colony which had had two queens in the hive for two months. We do not know how much longer the state of domestic affairs might have existed; but needing an extra queen for a queenless hive, we removed one of the queens.

SUPERSEDING QUEENS; A QUESTION.

Four years ago I bought three queens from I. R. Good, and two of them died; but the other lived till about a month ago, and proved to be a very prolific one until this spring. I noticed that the colony did not recruit as fast as it should, therefore I supposed the queen had died, and I opened the hive and made an examination and found her apparently well. But I noticed that the brood and eggs she laid were very irregular, and not very much of it. I also noticed that the bees had prepared cells ready for her reception, but she would deposit an egg only here and there over the combs. I did not like to kill her, so I thought I would wait a little for further developments of the case. About the 1st of June a friend of mine came to see me and I told him about it. He said I must be mistaken about the queen being alive; and to satisfy him that I was not, we opened the hive and found her. But here came the surprise to us both—a colony of about a quart of bees, with cells, started as though they were going to swarm. The queen was still laying; but we noticed that she was not well. Her wings looked as though they had been singed by fire, and she looked very stupid, so we closed the hive to wait for further developments of the case, and see if they were going to swarm or not. The queen-cells looked as though they were about five days old at the time. In about ten days I opened the hive and found a fine young queen hatched, and the rest of the queen-cells torn down, and the old queen lying at the entrance of the hive dead. This young queen has been laying some time, and the bees are working with a will. But heretofore, in the later days of the old queen, the bees were almost dormant. What we want to know is, if the queen knew that she was going to die, and had the bees form queen-cells, and she deposited eggs in them, for a young queen, or did the bees form the queen-cells and put the eggs into them? and, when they were sure of a young queen, kill the old one and throw her out of the hive? or did the bees and queen work together in order to save the colony?

Linkville, Ind., July 12, 1887.

J. KUNZ.

Friend K., your experience is nothing new, as you will see by the A B C book; in fact, it is the usual way for queens to be superseded, only you are wrong in thinking the young queen killed her mother. I do not believe they ever do this, for we have so many times found a young queen assisting the old one; and there have been so many reports in our back volumes of this same thing, in my opinion it occurs very much oftener than we know of. I have known old queens to do very good service, even when their wings were shriveled up, and when they moved about on their combs like an old gentleman or old lady. When queens begin to look old in this way, one or more cells are usually to be found; and the first queen that hatches usually destroys the other cells. Unless honey is coming in bountifully, the old queen may remain in the hive several weeks or even months, after the young queen commences laying; but sooner or later she becomes too feeble to hang on the combs, drops to the bottom of the hive, and is dragged out as any other useless piece of furniture.

BEES AND CHICKENS.

As I first mentioned chickens as drone-brood and drone-eaters some time ago, perhaps the readers of GLEANINGS are under the impression that I keep both in one yard, which is not the case, as I well know how much the disadvantages outweigh the advantages in so doing, as described by Grant Scofield a few months ago. But he has missed, or not yet experienced, the worst of the evils derived therefrom, and of which I should like to inform your readers. Last year I had several hatches of young chickens, of which some escaped through the fence. They soon made good drone-catchers and bee-eaters. Three got stung over the eyes, of which but one recovered, and two died in great agony after several days. I would have killed them to relieve them, but for the fancy stock. While I agree with all, that bees and chickens are nice to keep together, they should be strictly kept in separate yards.

Hammonton, N. J.

C. H. LUTTGENS.

FRADENBURG'S PORTABLE BEE-BRIDGE.

I have just come in from doing a good job for the bees in the apiary; and that is, putting a substantial bridge to each hive. I have always seen the lack of some good device for the bees which drop short of the alighting-board to crawl over, and get into the hive. But I have it at last. Take a piece of board, equal in length to the width of your hive, and from 6 to 12 inches wide. Bevel both edges from the same side.

Then drive 2 common wire staples on one side, one near each end. This is the bridge complete. Now take a hammer, 2 wire nails one inch long, and a pair of nippers. Go to a hive in the apiary and drive the nails in the front edge of the alighting-board, the same distance apart, and corresponding to the staples on the bridge. Leave $\frac{3}{4}$ inch of the heads out. Next take the nippers and bend the head up so as to form a hook. You can then slip the staples of the bridge over these hooks, and let the other beveled edge rest on the ground. You want one to every hive in your apiary. It is cheap, durable, and easily applied; and if the staples and nails are all driven by a gauge, all will be inter-

changeable, and readily taken off if desired, and no bee-hive will be complete in the future without one.

A. A. FRADENBURG.

Port Washington, O., June 30, 1887.

Friend F., your bridge for hive-entrances is exactly what we used ten or twelve years ago; and if I am not mistaken they were described in GLEANINGS. The warping of the boards under the sun and rain was one great objection. We put in cleats to prevent this, but they got to be troublesome. Whenever a hive was to be moved they would be flopping around; and when taken off they were thrown aside, and got to kicking about the apiary so that we finally banished them entirely, preferring the sand and sawdust, with salt sprinkled over the latter, when weeds threatened to intrude.

A GALVANIC CURRENT FOR ASSISTING IN WIRING FOUNDATION.

I don't think we in Australia can teach you much about bee-keeping; but we have a way of fastening foundation into wired frames, that I have not seen mentioned in any American books or journals. It is McEllery's method, and I inclose a clipping from the Australian *Bee-Keeper's Journal*, showing how to do it. It is a good thing.

H. LINDSAY MILLER.

Warrnambool, Victoria, Aus., May 16, 1887.

FIXING FOUNDATION IN WIRED FRAMES—MC-ELLERY'S METHOD.

The methods usually adopted for fixing foundation in wired frames are either to rub the wires into the foundation with a *grooved button-hook*, or some tool of the kind, or to press it in with "Blood's roller" (an American device), or, better, with Mr. Root's "rocking tool," an instrument like a portion of the periphery of a wheel, with a few sharp teeth on it. Each tooth is rolled on to the wires, and imbeds them in the foundation. Foundation fixed by any of these methods is apt to part from the wires and curl up in very warm weather, or when used for newly hived swarms. The fact is, there is no real union between the wax and the wires unless the wires are heated. I have tried several plans for doing this, but none so satisfactory as warming the wires with a galvanic current from a good large single-battery cell. The mode is very simple. Lay the foundation on a board which fits inside the frame; now lay the frame horizontally over the foundation, so that the wires lie nice and evenly on the foundation; take the wires from the two poles of the battery, one in each hand, and touch the two ends of each frame wire for a moment, one end with the positive and the other with the negative wire of the battery, and the frame wire becomes heated, and melts its way down to the *septum* or *midrib* of the foundation; touch each wire of the frame in succession in this way, and the whole is fixed quicker than by any of the other modes, and so firmly that you can tear the foundation away only by piecemeal. If your battery is not strong enough to heat the wire the whole width of the frame, do it in steps, and you will find even then you can do it more quickly than by any of the other plans, with the satisfaction of knowing that the wires are as firmly attached as is the case with the foundation where the wires are imbedded during the process of manufacture.

WHAT BECOMES OF THE FEW REMAINING BEES AFTER HIVING A SWARM.

Some of my friends and myself have been discussing the question of what becomes of the few remaining bees usually left in the tree, or upon the limb, after hiving the young swarm that clustered thereon. Some claim that they return to the mother hive; others claim that just as soon as the young swarm find that they have a home of their own they will visit the tree, or limb, where they clustered, for several days after they have been hived, and

it is *my belief*, for the express purpose of calling in all *absentees* which may have been left, and they will return with them to the new hive. Now, Mr. Root, will you be kind enough to give us your opinion in regard to them?

E. B. RIPLEY.

So. Windsor, Conn., July 4, 1887.

It is my opinion, friend R., after considerable close observation, that the bees scatter and go wherever they happen to—into the parent hive if it is near by; if more convenient, into other hives, and sometimes, if the new swarm is located so near they can find it, they go in a body to join their comrades.

WHAT TO DO WITH POLLEN IN OLD COMBS.

Can you tell me what to do with combs that the bees have literally packed with pollen? They certainly have no use for so much, and it takes up so much room.

R. J. MATHEWS.

Riverton, Bolivar Co., Miss., June 23, 1887.

Friend M., it is quite a difficult matter indeed to get the pollen out of combs unless you can make the bees take it out for rearing brood; and in this way we have disposed of all we have had in our brood-rearing operations, many times needing even more. In our back volumes, plans have been given to throw it out with the extractor, after being softened with warm water, or by steaming the combs. It is a nice operation, however; for if the pollen is not warm enough it will not come out; and if you get the combs too warm, the wax will be so soft as to break them out of the frames.

EVIDENCE THAT KING-BIRDS DO SWALLOW WORKER BEES.

I notice in GLEANINGS, July 1st, page 514, in your foot-notes to J. T. McCracken's article, that you would like to hear from the readers in regard to king-birds swallowing bees. Some weeks ago there was a couple of king-birds sitting on a bush close to the house, and my brother had observed them catching some of the passing bees, and mentioned that we had better shoot them. I said I believed there were no shells loaded with fine shot, and so paid no attention to them for a few hours, when, on stepping out into the yard, I noticed them picking up bees rather too fast to suit me. I then went into the house, found one or two loaded shells, took out the gun, and shot one of the birds. Upon examination I found that it contained what I should have pronounced the remains of quite a number of worker bees. It may be that some of the birds get up to the business so well that they just catch the bees in their beak, and, after squeezing out the honey, drop it; but my opinion is, that very few birds are so highly educated.

Bluffton, Mo., July 13, 1887.

S. E. MILLER.

QUEEN-CELL PROTECTORS; THE BEVELED EDGE OR SQUARE JOINT, ETC.

I wish to report my luck with Doolittle's queen-cell protector. I have used them constantly this season in my apiary, and I will say I have the first cell to be destroyed; but I have lost more young queens after they had hatched from the protector, than by the old process; but I think the cause was, that the bees were not gathering honey, and they killed them. The first show of honey in sections was the 16th of June. I think the protectors are a prize to bee-keepers, as it is more quickly done, and

that is a great saving of time. The honey-crop will be small in this section, unless there is a very heavy flow from fall flowers. Bees do not swarm very much here. Out of 31 colonies, only 12 swarms up to date. They are extra strong in bees, hanging out in all kinds of weather.

Please do not do away with bevel edge of hives, as they are no account with a flat edge. I have them both. Give me beveled-edge hives and metal-cornered frames, and it is a pleasure to keep bees.

King-birds are a pest to bee-keepers. They destroy more queens and workers than all the toads. They do not swallow the workers, but simply take them, one after another, on the wing, until they alight, then they press out the nectar and throw the mass of bees out. This is a fact. I use a gun freely.

JOSIAH EASTBURN.

Fallsington, Pa., July 7, 1887.

NOTES AND QUERIES.

HOW TO MAKE AN UP-GROUND WINTER REPOSITORY.

I WISH to construct a cellar above ground, to winter my bees in, about 40 stands. I wish to make it of lumber, having double walls filled with sawdust. Will you please say how much space you would leave for sawdust? Would two feet be about right?

H. LATHROP.

Brownstown, Wis., July 20, 1887.

[Two feet would no doubt be an absolute protection against frost, friend L.; but I don't believe there is any need of such very thick walls. The house for wintering that we used for many years had only eight inches of space, and there was never any trouble by frost getting inside, that I remember of.]

DECOY HIVES.

Two instances of the same place being occupied by swarms coming year after year are reported here—one in a hollow apple-tree, the hole being stopped with a board, the other in a house.

W. M. BADCOCK.

Basking Ridge, N. J., June 25, 1887.

FAVORABLE TO FLORIDA.

I have good news for this part of Florida. We have had our gallberry bloom, and are having saw-palmetto bloom, with black mangrove and cabbage-palmetto to hear from. My best colony up to May 13 gave me 109 lbs. in $4\frac{1}{4}$ x $4\frac{1}{4}$ x $1\frac{1}{2}$ sections, and others are doing well. This colony has not swarmed this season; and, by the way, they are black, or native bees.

S. C. CORWIN.

Sarasota, Fla., May 16, 1887.

THE THEORY OF SWARMING.

What is the theory about swarming, further than overcrowding? When I was young I thought the young queen led out the young bees to establish a home of their own. We now know that the old queen leads out the old bees, and others that wish to follow. It seems unnatural for the old bees to pack up and abandon the product of their hard summer's work.

P. S. DILWORTH.

Allegheny, Pa., July, 1887.

[You are right, friend D. It does seem unnatural for bees to work for stores, and fight for the defense of these stores as they do, and then to voluntarily abandon it, and start to commence anew in an absolutely empty hive. But facts are stranger than fiction, as you have probably heard. This matter is pretty thoroughly discussed in the ABC book.]

CHICKENS AS WORKER EATERS.

On page 514, under the head of "Do King-Birds Swallow Their Victims?" I. T. McCracken claims that chickens do not eat worker bees. I will say here, that chickens do eat workers or drones. I have seen a chicken stand by the hive and catch the bees as they go in, laden with pollen.

Blackville, S. C., July 13, 1887. D. D. SLATER.

A STALK OF ALSIKE 5 FT. 7 IN. LONG.

I see a little talk in GLEANINGS about alsike clover. I will send you one stalk. This stalk was five feet seven inches long when first taken from the field. I have about $\frac{1}{4}$ acre, all of which will compare with this stalk. This is the pink-edged alsike.

A. E. GRIFFITH.

Copley, Ohio, July 12, 1887.

FURTHER TESTIMONY FROM PROF. COOK.

I have received a stalk of clover from Mr. Griffith, Copley, O., with the request that I comment upon it in GLEANINGS. 1. It is alsike clover; 2. It is fully 6 feet long and $\frac{3}{4}$ of an inch in circumference. A farmer just in my study says he had this year a field of alsike clover on low clay land, that yielded as heavily as any field of red clover he ever saw.

A. J. COOK.

Agricultural College, Mich., July 18, 1887.

WATER-LEAF.

I inclose you a specimen of what is certainly a remarkable honey-producing plant. What is it? Can it be cultivated to any advantage? Each stalk produces quite a number of clusters like the one inclosed. You will notice the bloom has been off for some days.

WM. IDEN.

Etna Green, Ind., June 24, 1887.

The specimen from Wm. Iden is water-leaf (*Hydrophyllum appendiculatum*).

EXPERIMENTAL STATION, per CRAIG.

A GOOD WORD FOR THE CARNIOLANS.

The Carniolan queen Dr. Morrison sent me last summer produces bees, the most gentle I ever saw; and they are great honey-gatherers too—as good as any we have seen, even the Syrio-Italians. They are a very strong colony in a Langstroth chaff hive; and while we were making a cistern, ground was thrown against them, and then we had to lift them and turn them around, which we did without smoke. No smoke or veil is required when handling them.

ILA MICHENER.

Low Banks, Ont., Can., June 27, 1887.

STRENGTHENING WEAK COLONIES.

Standing in my yard are 22 colonies, all of them good and strong. This is the way I make strong stocks out of weak ones. When I get a weak swarm I put it in a hive and fix it in as good shape as possible; then when another small swarm comes off I lay a newspaper in front of the weak hive, get my small swarm, put it on the paper, start them for the hive, and they go in and go to work, and I have a swarm of bees that even this year (for there is no honey in the white clover) fill their hive up in a week or ten days.

W. M. WEBSTER.

Kendall, Mich., June 20, 1887.

[Your plan will work usually, whenever the bees are swarming, friend W.; but unless there is a flow of honey, a great many times your reinforcements will be stung to death almost as soon as they approach the entrance. Better have your smoker in good trim, and watch them until you are sure they are well received.]

REPORTS DISCOURAGING.

NOT A SPOONFUL OF HONEY.

FROM the looks of a late GLEANINGS it would seem as if you had no one to help you keep up the department devoted to Reports Discouraging. Well, if that is the case we should like to help you out a little. We have not had a swarm to issue this season, and have heard of only one or two who did, and those were early in the spring from hives where the surplus honey had been left on over winter. We also hear that John Nebel & Sons and T. Anderson, two of the leading bee-keepers of this county, are faring no better than ourselves. Mr. C. H. McFaddin, of Clarksburg, Mo., reports the same thing. We have not had a spoonful of this year's honey.

Bluffton, Mo., July 7, 1887.

MILLER BROS.

The honey crop is a failure in this section. White clover failed, and no surplus from that source—only a little from basswood.

H. R. BOARDMAN.

East Townsend, O., July 12, 1887.

Bees are doing poorly here. Unless buckwheat and late fall flowers give us a flow of honey we shall have to feed to keep them alive through the winter.

T. T. DAVIDSON.

Parkersburg, W. Va., July 5, 1887.

The honey crop is a failure here. It will not pay one per cent on capital invested. I will give you the whys and wherefores shortly. All the whole State is in the same boat.

J. P. ISRAEL.

Olivehain, Cal., May 30, 1887.

POOR PROSPECTS.

Bees are doing but little here. No swarms yet, and none of my 200 colonies are making surplus honey. We are having extremely dry weather, with cool nights and north winds. We do not think we shall get any clover honey.

J. V. CALDWELL.

Cambridge, Ill., June 10, 1887.

THE WORST SEASON SINCE HE HAS KEPT BEES.

Bees are not doing much in the way of surplus honey, although there is an abundance of bloom, both clover and basswood. The weather has been most unfavorable since I have kept bees. Mine have not filled half a dozen sections to the hive; a little better in the boxes for extracting.

Morristown, Ind., June 27, 1887.

L. DYER.

HONEY SCARCE.

I see by last GLEANINGS that the honey crop is going to be a failure in a great many localities this year. There is no surplus here from clover or linn. Oats and corn are drying up with heat, and very poor prospects for any buckwheat honey. If we don't get rain soon it will be a failure. The demand for honey is increasing. I think 10-cent clover sections will be scarce this year.

Rimer, Pa., July 8, 1887.

S. HEATH.

ITALIANS AHEAD.

The prospect here is gloomy; drought—unmitigated drought—cold nights, no dew, pastures burned up; white clover bloomed ten days earlier than usual, but yielded no honey. I have only a few stocks of bees, all blacks but one. The blacks I shall have to feed. The Italian stock is filling one or two brood-combs, and may live. The Italians rise earlier and go to bed later than the blacks.

J. HAMILTON.

Beason, Ill.

FAILURE OF HONEY CROP FOR C. C. MILLER.

Our surplus-honey crop has come and gone, and many colonies have less honey than when taken from the cellar. The worst drought ever known here has prevailed, and clover in some places is burned dead, root and branch. From what I can learn, the drought has extended over a large surface. July 1 the drought was broken by a glorious pour of rain; and, if too late to save the honey crop, it is some comfort to know it has saved the corn crop.

C. C. MILLER.

Marengo, Ill., July 7, 1887.

THE WINTER LOSSES OF BEES IN MAINE.

A word as to the honey prospects for the season in Maine may not be uninteresting to your readers. The season opened late, one of the hardest winters ever known lingering into spring. This fact caused a great many weak colonies of bees where all did not die outright. I think, as near as I can gather statistics of bees in this State, that the loss by dying might be set at about 40 per cent of the whole number of colonies; add to this the weak colonies, of which every apiary has a share, the loss, as compared with last season, is fully 50 per cent. As far as I can learn, bees wintered in the cellar, at a temperature of 40 to 44°, passed the winter in much better shape than where the hives stood on their summer stands. Bees which were in chaff hives, or otherwise thoroughly protected, wintered with much less loss than when unprotected. In my case, 9 out of 11 colonies came through the winter and died in May.

The harvest of honey from fruit-bloom has not been equal to the average one; the cause being, no doubt, the weak condition of the colonies. Last year, swarms issued as early as May 23, and kept it up through the close harvest of honey. This year, the earliest swarm I have heard of issued about the 12th of June.

In many sections of the State, the spring, up to June 20, was exceptionally dry, but little rain falling after the last of April. But the excessive amount of snow of last winter coming upon the ground before it was frozen any, and remaining till settled warm weather, gave us fields free from winter-kill, and white clover in abundance. The clover is just now coming fairly into blossom, and bees are at work upon it. We are hopeful of a bountiful honey-harvest from the clover.

L. F. ABBOTT.

Lewiston, Me., June 21, 1887.

PROSPECTS POOR.

Never, in the recollection of the oldest inhabitant, has there been so complete a failure in honey as I am bound to report from this section of country this season. There was a very profuse white-clover bloom, but almost an entire absence of nectar. Linden produced a very meager flow, and many colonies have not the wherewith to pass them over another winter, and will have to be fed, should we have no fall harvest. Last season, in an apiary of 49 colonies I harvested 472 lbs. of honey by Aug. 13; whereas, up to the present date not one ounce has been taken, and probably will not be very soon. This state of circumstances seems to embrace a large per cent of the State, and probably of the whole country, if we are to credit reports from various sections. I am constantly interrogated by friends and neighbors as to why our bees don't swarm; and my answer has been, "No honey in the bloom;" but the question comes here: Why

this absence of honey? I should like to hear friends Root and Cook theorize on this subject. Should we not be able to remedy the difficulty, it would at least be a satisfaction to know the cause. During the height of our clover bloom, when hill and valley were robed in white, bees were in a starving condition, and no nectar whatever coming in. To say that I am discouraged is not the fact in the case. I shall ever keep the guiding star of hope in view, believing it to be "an evil wind that blows no man good;" and though misfortunes come, we must make the best of circumstances, and wield them to our own good.

Spring, Ill., July 21, 1887. J. M. HAMBAUGH.

Friend H., so far as I am concerned I can not even suggest the reason why there should have been little or no honey in the white-clover bloom this year, and this, too, over such a vast expanse of country. It was not there, and that is all we know about it. The same thing has happened before; but never before has it been so general, the country over. It seems to me it is like inquiring why it rains sometimes and does not at others; that is, so far as I can see it is a matter entirely beyond our control.

BLASTED HOPES.

NO BREAD AND BUTTER AND HONEY, THIS YEAR.

YES, we have it terribly—never had it before. We can truly sympathize with those who have had a like experience. We started out in the spring with 48 swarms, all in good shape; yes, they were booming, and our prospects were bright. They were arranged in four rows in the apiary, seven feet apart each way. They looked nice in their little white cottage-roofed houses—were admired and gazed at by all who passed. I was proud of them. I was, for a fact, and here may be the cause of my present condition. As the season advanced, the drought came with a relentless grip. The hot sun soon used up what little white clover escaped the severe winter, and, in fact, all other flowers. As a result, to date, I have not a single new swarm nor a pound of surplus honey; and as I look over the apiary this morning there are three vacant places, and many more must follow soon. It is truly sad, thus to part with my little friends; but sadder still the pleading of my little grandchildren, Beth and Joe, who beseechingly plead, "Grandpa, we want some bread a' butte' honey," and I am powerless to give the honey. It was never so before.

But I am not alone. Others in this vicinity are in the same condition. Those who were near the linn had a slight show. We are not thus located. The prospect for fall flowers is exceedingly slim. We have not had a good rain since May, 1886. But I am bound to take up with friend Hutchinson's advice—"keep a stiff upper lip."

J. SWIFT.

State Center, Ia., July 18, 1887.

We like the ring of your words, friend Swift; even though they do sound forth Blasted Hopes. We sincerely hope and believe that you will "keep a stiff upper lip," and that in another year grandpa may be enabled to sweeten the mouths of the dear little ones with "bread a' butte' honey."

NOT ONE POUND OF HONEY.

At last I must go into Blasted Hopes. The drought in this part of Wisconsin has killed the clover, root and branch, so that our great honey crop from white clover, beginning June 1st, lasting 40 days, is an entire failure. Bees bred up strong on raspberries, but no swarming. I do not think there is one pound of honey to the hive in my yard, as we never have any fall yield here. I can not see any possible chance to save even one single swarm from extermination. There will not be one pound of surplus raised in this vicinity. E. A. MORGAN.

Columbus, Col. Co., Wis., June 20, 1887.

REPORTS ENCOURAGING.

THE BEST SEASON.

THIS has been the best season we have had in a long time, but the bees have swarmed too much. I presume I have had 300 swarms. Most of the first swarms have sent off from one to three. It has been a continual flow of honey since spring. If I could keep my bees from swarming I could make piles of honey. I shall make, or shall have made, about 6000 lbs., mostly in sections, 3 x 3—a little less than a pound, for which I expect to get from five to six cents above the market price of one-pound sections, or, at least, I have years before.

C. M. LINCOLN.

Rupert, Vt., July 20, 1887.

ANOTHER STORY FROM REAL LIFE.

CHAPTER I.—JUNE 15.

You say you want reports discouraging. I will give you one that takes the lead of them all. Last fall I had five swarms, and now I have none. My last one died the 14th of this month, from the want of stores. Bees are not making their living here now.

CHAPTER II.—JULY 15.

Bees are doing well. They are making lots of honey here now. The 9th of July there was a swarm came from some other place, and went into one of my hives that had bees in last year. They are doing nicely.

C. H. STEWART.

Altona, Col.

DOING THEIR DUTY.

Bees in this locality are doing their duty, gathering the sweets. This spring I transferred ten colonies from the old-fashioned hive to a hive that suits me some better. They have the lower part all filled snug and good, and are at work now filling the sections, which consist of 15 1-lb. sections on each stand. Basswood is just in full bloom, and a good prospect for a large yield of honey. I have alsike clover sown, 4 or 5 acres. I also have buckwheat in full bloom.

S. B. TEDROW.

Caledonia, O., July 2, 1887.

NO CAUSE FOR COMPLAINT.

There is no surplus from white clover, but we have had a good start in sections from alsike. Basswood is in full bloom, but the crop, I think, will be short. Teasels so far have not been touched. They will be in full bloom as basswood closes, and will give us at least 10 days additional. If it were not for this I fear I should be left with many partly filled sections. Taking the season as a whole, there is no cause for complaint.

C. M. GOODSPEED.

Thorn Hill, N. Y., July 11, 1887.

MYSELF AND MY NEIGHBORS.

The servant of the Lord must not strive; but be gentle unto all men, apt to teach, patient.—II. TIM. 2:24.

I BELIEVE we are, as a rule, in the habit of underestimating our neighbors; that is, we consider ourselves about right, but we see *their* faults and failings very plainly. I don't believe we have charity enough. I don't believe that, as a general thing, we pay enough attention to their good qualities and lovable traits—at least, I know that is the case with myself; but if there is any thing hopeful in the fact that I am beginning to see my own faults lately, as I never saw them before, I think I may take courage. A few days ago I undertook to remonstrate a little with my wife in regard to something she had said. She instantly replied that I was guilty of the very same thing; namely, hasty and thoughtless words. I told her she must not take me as a pattern. Her reply was, that I never need expect her to do any better than I did. It was said a good deal in jest; but it has troubled me since; that is, I have felt troubled to think that my example is not better. I am not only a professing Christian myself, but I take upon myself the responsibility of teaching. Many look up to me as a spiritual teacher; and I tell you, my friends, it is important that one who undertakes to be a servant of the Lord be gentle unto all men.

Now, although our neighbors are, as a rule, good people, and people who mean to obey the laws of the land, if not the laws of God, there are some exceptions. Sometimes we have neighbors who are very bad. What shall we do with them? "Let them severely alone," some may answer; but the Bible does not say so. On the contrary, it says we are to take an enemy and heap coals of fire upon his head. It says we are to love bad people, and do good to those who hate us. Well, I believe I have a good many times shown considerable grace in loving my enemies, and in doing good to those who hate me. Suppose, now, for instance, you have a neighbor who is guilty of crime. What shall you do in this case? The world says, "Have him promptly arrested;" and the Bible says, also, that a good many times the welfare of this very neighbor demands that he be arrested and punished according to law. We ought to be very, very careful however, I think, in such matters. If it is really true, that you have a neighbor who has repeatedly transgressed the laws, and proposes to transgress them right straight along, presuming on the good nature or easy way of those about him, no doubt he should be taught a lesson by prompt punishment. A servant of the Lord, however, should be very sure that he is right in deciding the law is the last alternative.

In our county jail I meet, every week, those who have committed crime. I sit down beside them, and, by friendly talk, get acquainted; and they, as a general thing, tell me plainly all about the matter, making due allowance, of course, for the different standpoints from which we see

things. Some of my good friends have censured me severely for going near these men—for showing sympathy or kindness for those who have behaved themselves so badly; and I have sometimes thought there may be such a thing as treating a criminal so as to encourage him in thinking his offense is a very light one—that he has been wronged and injured—that the laws, and the officers of the law, are too severe. My disposition, perhaps, would lead me to be weak in this respect. It is very hard for me to be severe and stern when I am talking with somebody pleasantly and quietly. When indignation fills my breast, however, I get harsh enough and stern enough, as everybody knows who knows me at all. In writing this last sentence that little prayer wells up, "Lord, help;" and I tell you there is need of that prayer often. Well, as I have said, a good many have wondered sometimes that I have patience, and could condescend to be pleasant and affable with those who are guilty of terrible and despicable crimes. Well, I go in to see those people, not as a judge, and not as one who is called upon to decide in any way whatever as to who is right or who is wrong. I go, simply as a spiritual adviser, and I go with the word of God in my hand, holding up Christ the Savior, to all, guilty or innocent. I feel that the Lord has called me to this kind of work, and I am happy in doing it. I believe these men are better men, even if they do not become Christians, because of the talks we have had together; because of the portions of Scripture I have read and applied with them; because of the Gospel Hymns we have sung together.

With all these years of practice in this line, you would naturally suppose me to be the proper person to talk with a criminal, out of jail as well as in jail. If a man should steal one of my horses, and I should catch him in the very act, you would naturally expect me to behave myself according to the teachings of the text; that, even though I made haste to recover my property, and make him give up his criminal intentions, I would be gentle and patient. My friends, I ought to be, I know; but I am afraid it would turn out a good deal as my good wife intimated. I am afraid I should not want anybody to pattern after me just about that time. Perhaps you ask, "Brother Root, what ought a Christian man to do, if he finds somebody in the middle of the night, attempting to get away with his best horse?" And this is the question that confronts me this bright summer morning. Most of you would say, "If he had any thing to shoot him with, he ought to shoot the horse-thief—that is, unless he gave himself up at once." Well, perhaps he ought to shoot the thief, rather than let him get away with the stolen property; but I think it will be a good deal better for me not to have any thing around to shoot with, at such times. If I could shoot a man, with a prayer in my heart for him at the time, may be it would be the thing to do; but I am afraid that Satan would put in a word, and, before I knew it, he would have the management of pretty much the whole affair.

To tell the honest truth, I am *afraid* of the prince of darkness. I am afraid of getting out of the reach of the Savior, for even one single moment. Yes, it is true, that, although I have taught and plead and urged men to turn from evil to that which is right and good, for years, I am afraid of *myself*.

Perhaps you wonder what has suggested all this. Well, to tell the truth, I have had a little experience in meeting crime in the wide open air, with no prison-bars about me or the criminal. He, of course, said he was not guilty, as almost all criminals do when they are in jail; but I had more of the facts in my possession than he was aware of. Was I gentle and patient? No, I was not. He was slow about restoring the stolen property, and tried to make out that it was not stolen, and that he ought not to be obliged to return it—at least not all of it. I talked penitentiary to him, but I did not talk it lovingly. I did not talk it as I talk with the friends in jail; I did not talk it as a Christian ought to talk it, and I feel ashamed of myself to think I behaved so poorly when God saw fit to try me in an open-air conflict with evil. It came on me unexpectedly, and my armor was off. I am afraid the poor fellow said, as he went away, "I have heard a good deal of talk about Mr. Root's Christianity, and of his great love for his fellow-men—even those who are unfortunate or bad; but I did not notice any of it shining in his countenance to-day." You may say, "Why, Mr. Root, even a minister of the gospel would perhaps do no better than you did. If he should find a man in the night, attempting to steal his horse, it is quite probable that he would be as harsh and severe as you have been, for the circumstances demand it. There is no time for soft words or exhortations to repentance, under such circumstances." To which I reply, that I am sure there is a better way than the way I did. I am sure that God's grace is sufficient for even such emergencies; and I am sure, too, that a man can act promptly and quickly; he can demand instant and immediate obedience of one who is caught in the act of committing crime, and yet he can do it with love in his heart, and with a spirit that may do much toward reclaiming the lost one. If you want light in this matter, read the life of Christ while he was here on earth. Notice carefully his way of meeting crime. Read, also, how Paul met wickedness and sin and crime. Keep in mind, that the loss of property is nothing compared to the loss of a human soul. I do not know how much has been done in this line, but it seems to me as if a vast field for Christian work were open here. I wonder if there is any such thing as a Christian detective. There are Christian policemen and Christian sheriffs and constables and marshals, and various other officers of the law; but my prayer now is, "Lord, help us all, in meeting sin and crime and Satan, in a way that will be most effective in disarming and robbing him of his power to ruin mankind; and, Lord, help us who profess to be thy servants, to be gentle unto all men—apt to teach, patient."

OUR ONE-STORY CHAFF HIVE.

ITS ADVANTAGES OVER THE TWO-STORY CHAFF HIVE.

I SHOULD like to say a few words in favor of your one-story chaff hive. I have used a good many different hives in my time, having kept bees for nearly 40 years. For the last three seasons I have been using your one-story chaff hive, with a Simplicity body and cover on top, as an upper story, and I consider this combination as making one of the best and most convenient hives now in use. And I will here add, that, with me, it has come to stay.

All bee-keepers who have ever used the two-story chaff hive, I think, are pretty unanimous in agreeing that it is one of the best (if not the very best) of hives for outdoor wintering that has ever been invented; but for a summer hive it has (in my estimation) some very objectionable features about it; and especially for raising comb honey on the improved or modern plan, now so extensively practiced by our most scientific bee-keepers.

The greatest objection that I have to the two-story chaff hive is, that it is always a two-story hive, which makes it rather inconvenient to get at the brood-chamber, and also in putting on and taking off our surplus arrangements for raising comb honey; but in the one-story chaff hive we retain all the good qualities and get rid of the bad ones, and get a much cheaper hive, and a more convenient one to handle and to work with. I have wintered bees in this hive (on their summer stands) for the last two winters, and they came out in splendid condition in every instance, and I don't see any good reason why it should not be just as good a hive to winter in as the two-story chaff hive. You may, perhaps, say, "Why not use our half-story (as we make it) in place of the Simplicity body and cover?" I will answer, Because of the following reasons: First, your half-story is too shallow; it will not admit of putting on more than one tier of sections at one time. Second, in using a chaff cushion or quilt over your bees in putting them up for wintering, you would be obliged to turn your half-story upside down, and drop your cushion or quilt into the half-story, and put it on in that way, which I consider a very poor one, for the reason that it gives you no chance to tuck down the cushion nice and snug, and make it all nice and tight in the corners of the hive, so as not to give too free upward ventilation, which I consider very important. A good many of our bee-keepers use loose chaff or forest-leaves in the upper story, for a winter protection; and with this material you would still be worse off with the half-story.

G. W. HARRISON.

Wharton, Wyandot Co., O., July 14, 1887.

Friend H., the points you make in favor of the single-story chaff hive agree with our experience. It has wintered colonies with us for the past three or four years successfully. If in colder climates it will do as well as the two-story hive it will surely take the lead. Our experience has taught us that a Simplicity body and cover is much better than the one-half-story cover alone for covering the small hive in winter. We should be glad to receive reports from other localities where these single-story chaff hives may be in use.

TOBACCO COLUMN.

THE EVIL EFFECTS OF TOBACCO ON THE SYSTEM.

I QUIT the use of tobacco more than three years ago, and I think it was the best thing I ever did. For the past ten years my health was very bad. I had palpitation of the heart for about ten years, and for about three years I was bothered with dyspepsia, weakness, trembling, and nervousness. I never thought that tobacco was at the foundation of all this trouble till something more than three years ago, when palpitation came very near ending my life. I had three of the best doctors in the town of Hickory, N. C., and they said there was but little chance for me. Before I finally recovered, the doctors said that it all came from using tobacco, and they told me to quit the use of it. I haven't used any since that time, and as a consequence my health has been better for the past three years than it had been for the past ten or twelve years before. I had used tobacco for twenty years or more, but I am very sure that I shall never use another crumb as long as I live, as I have enjoyed so much better health since.

Hickory, N. C., July 1, 1887.

JAMES DRUM.

Friend D., your letter reminds me of a certain relative who visited us about a year ago. He kept a drugstore; and when he was waiting for customers he used to chew and smoke. His health began to fail, and no one thought of the reason until finally he was taken one day on the street, with bleeding at the lungs. A long fit of sickness followed, from which he just made out to recover. His physician then told him that tobacco was the cause of it all. He broke short off, and passed through a terrible scene of mental suffering, much as intemperate men do when they suddenly break off from stimulants. At the end of one year, however, he became bright, happy, and well, and now laments that a great part of his life was made miserable and almost useless by being a slave to tobacco.

I have quit the use of tobacco; and if I commence it again I will send you the money for the smoker.

Beason, Ill., May 31, 1887.

J. HAMILTON.

I have quit the use of tobacco. If I ever resume the use of the weed I will pay you for the smoker.

Danville, Ind., May 22, 1887. G. W. MCPHEETERS.

I used tobacco for two or three years, but have quit for over a year. If I break my promise I will pay you for the smoker.

C. F. ANDREW.

New Salem, Ill., May 10, 1887.

If you will send a smoker to me I will quit the use of tobacco; and if I ever use it again I will pay \$5.00 for it.

A. D. BENTON, JR.

Benton, Ind., June 5, 1887.

We need a smoker; and Henry says if you will send him one he will quit using tobacco; and if he does not, I will make him pay for it.

J. UMMEL.

New Goshen, Ind., June 2, 1887.

HAS USED TOBACCO 40 YEARS.

I smoked and chewed tobacco for over 40 years. I have quit it altogether, and will stay quit, or pay for the smoker, if you will send me one.

Bolivar, Pa., June 7, 1887.

W. REYNOLDS.

I have been an occasional smokers of cigars, but am going to give it up. If you send a smoker, I will pay you for it, if I commence the habit again.

Berlin, Wis., May 20, 1887.

J. W. COON.

I have used tobacco for the past thirty years, but will use it no longer; and if I do I will pay you the full or double price of the smoker.

A. W. BECKWITH.

Poquonoc Bridge, Conn., June 19, 1887.

I have quit the use of tobacco in all its forms. Please send me a smoker; and if I commence again I will send you the full price.

MRS. S. A. BOWMAN.

Wabbaseka, Ark., May 24, 1887.

My husband used tobacco 16 years, and has quit. Please send him a smoker. If he commences again I will send you the price of the smoker.

MRS. WALTER MCALISTER.

Eden, Ill., May 27, 1887.

I have quit the use of tobacco. If I ever again commence the use of it I assure you I will send you the 70 cts. for the smoker. But I don't think I ever shall.

E. REICH.

Greensboro, Ga., June 6, 1887.

I used to chew tobacco a good deal, but I have given it up. I shall be very much obliged to you if you will send me a smoker. If I begin to use it again I will send you the price of it.

Brightseat, Md., Apr. 6, 1887.

W. BARRON.

Friend B. F. Heashey has quit the use of tobacco for over two years, and he thinks he is entitled to a smoker. He says if he commences the use of it, he will pay for the smoker.

Ashland, O.

My father has quit tobacco. He used it for about 25 years. If you think he is entitled to a smoker, please send him one; and if he commences again I will pay for the smoker.

J. R. ALEXANDER.

Alexandria, N. C., July 4, 1887.

I have quit the use of tobacco, and will promise to pay for the smoker if I use the weed again. There are other bees kept in this vicinity, to whose owners I will recommend the smoker if I like it.

C. M. LEONARD.

Bridgewater, Mass., June 11, 1887.

I have been a user of tobacco for years. You have led me to see the folly of its use, besides the injury it is doing me. If I use it again I will pay for the smoker.

J. D. POWELL.

Green Ridge, N. Y.

Pa has quit using tobacco in every form, and is trying to get everybody else to quit. He has two stands of Italian bees, and if you will send him a smoker I will see it paid for if he uses any more tobacco.

J. S. BROWN.

River Side, N. C., June 1, 1887.

In conversation with Mr. Silas Holley, of Locust Grove, Fulton Co., Pa., he told me that he had quit using tobacco a short time since. I informed him that you would send him a smoker if he would promise to never use tobacco again. He said he would certainly promise. If you send Mr. Holley a smoker I will see that you get your pay if he begins again. I showed him GLEANINGS.

B. M. STAHR.

Washington, Md., June 11, 1887.

I hereby promise not to use tobacco in any form in the future, if you will send me a smoker; and if I break my pledge I am to pay you for the smoker.

Smithville, W. Va., May 31, 1887. S. E. SMITH.

I will promise you not to use tobacco after this date, if you send me a smoker; if I do, I will send you the money for it.

Randolph, Portage Co., O., June 20, 1887. W. A. LADD.

A USER FOR 37 YEARS.

I used tobacco 37 years; and on the last day of last December I quit, and intend to stay quit. Send me a smoker; and if I break over I will pay you for it.

LEVI S. DAVIS.

Andersonville, Ind., June 7, 1887.

I apply for a smoker for my husband. He promised if he got one that he would never use tobacco to smoke the bees, or any other way, again. If he does I will at once send you \$1.00 for the smoker.

Barron, Wis., June 1, 1887. C. M. HANSEN.

I have given up the use of tobacco entirely. It has been 32 days since I tasted any; and as I am a bee-keeper I take advantage of your liberal offer. If I get to smoking and chewing again, I will send you pay for the smoker.

T. E. REID.

Greensboro, Ga., June 1, 1887.

Below are the names of two young men who have given up the use of tobacco. If they are entitled to a smoker, please send them one. T. J. Webb, and Jesse Sexton. I have given up the use of tobacco; if I commence its use again in any form I will pay for the smoker.

L. J. WEBB.

Webbville, Ky., June 19, 1887.

I have two brethren in Christ, who, by the help of God, have quit the use of tobacco, and have promised me if you sent them a smoker they would pay for it if they used the weed again. I will stand good for them. Their names are Rev. J. D. Stringer, Dripping Springs, Hays Co., Tex., and Thos. Roundtree, same place.

J. H. MORRAND.

Dripping Springs, Hays Co., Tex., May 21, 1887.

A HARD FIGHT.

My father has quit the use of tobacco. He is now 51 years old. He has not taken a chew or a smoke for two years. I heard him telling a neighbor to-day that it was the hardest fight he ever had, to break off. Please send him a smoker as a pledge; and if he ever takes to the use of it I will pay for the smoker.

W. HENDERSON.

Roney's Point, W. Va., May 19, 1887.

"AFTER A SEVERE STRUGGLE."

I notice through GLEANINGS, that you make a remarkable offer to those who will abandon the use of the "filthy weed." I have been a great user of tobacco, but have given up the habit, after a severe struggle. If you will send me a smoker I will promise faithfully to pay you for the same, should I fail to "hold out."

WILLIAM WEST.

Galena, Md., May 26, 1887.

Mr. John Dunn, of this place, has quit the use of tobacco. Mr. Dunn came to my place last fall, to see me put up my bees for winter; and while looking on he said if he would have a smoker he could handle his bees better too. I told him how he could get one very cheap—by laying away his tobacco. He did not like to do that, but said he would try, and I am glad to tell you that yesterday

he came to my place again and told me that he had not used any tobacco since he had been here in the fall, and is willing now to pledge himself never to use it again. He also promises, if he ever uses tobacco again, to pay you well for the smoker. Mr. Dunn is a young man about 20 years old, and stands high in society.

J. H. HIME.

McAlisterville, Pa., June 7, 1887.

I have a young man in my employ who has been addicted to the vile habit of using tobacco, for a considerable length of time. I told him that if he would discontinue the use of it you would give him a smoker. By considerable persuasion I induced him to leave off the habit. He has not now chewed any for a considerable length of time, and he says if ever he chews again he will pay for the smoker.

J. G. CHANEY.

Westboro, Clinton Co., O., June 7, 1887.

OUR OWN APIARY.

CONDUCTED BY ERNEST R. ROOT.

A CAUTION TO BEGINNERS.

OUR honey-flow began to taper off about the 15th of July, and on the 18th it stopped abruptly. The aroma of unripened basswood honey was strong, and one could detect it quite plainly a rod or two from the apiary. The sudden cessation of the flow of nectar, and the aforesaid aroma of new honey, made the robbers so persistent that we could scarcely work over the hives, even with the tent. A day or so ago, as I sat at my desk, Mr. S., one of the apiarists, came in and said:

"Ernest, the robbers are acting pretty bad. I wish you would come and tell me what to do. They seem to be getting worse."

As we proceeded together, said I, "You must have given the robbers a sip of honey."

"Why," he said, "I just took off a wide frame filled with sections of honey, leaving one or two sections partially filled, on top of the frames. I then carried the filled sections to the honey-house. When I returned, a minute after, the robbers were boiling over every thing. I immediately closed the hive and threw a tent over it."

When I got to the scene of operations I found that there were several good handfuls of bees here and there, around different portions of the tent, tumbling over each other in their vain endeavor to effect an entrance through the mosquito-netting. Not to be thwarted, the little lovers of ill-gotten sweets had suddenly pounced, with all the energy imaginable, upon the entrances of the adjacent hives. The inmates of these hives, evidently astounded at such a pell-mell invasion, did not at first repel their foe, and for a few moments a general uproar seemed imminent. Over a weaker colony, Mr. Smith had placed another tent. The stock of tents by this time had run out; and in despair, Mr. S., as before related, asked for further instructions. He had, in fact, under the circumstances, done all that

could be done; for by the time I got there the bees of the neighboring hives had begun to apprehend the danger before them, and, in consequence, were fighting their invaders with as much vim as the latter had attacked them at the onset. I told Mr. Smith not to examine any more hives for the time being, but in the mean time to mow grass around the hives. While doing this, however, he was to watch the actions of the robbers.

For two days after it was well nigh out of the question to work with the bees at all, even with the aid of the tent. While the latter prevented the robbers from entering the hive for the time being, yet when it was removed they would pounce upon the entrance of the stock just examined, in the manner I have described. On the third day after the robbers had gotten their sip of the new basswood honey, by working carefully with the tent the work with the hives was resumed as before.

As is stated in the heading, this incident is not related for the benefit of veterans, but for beginners. To these latter (who probably form the major part of my readers) I reiterate: Do not, under any consideration, let robbers at this season of the year get a sip of new honey. If you find a few robbers hovering around just as you get your hive open, close it up immediately. Before opening it again, use your bee-tent. If you have no such convenience, do the necessary work with the bees at twilight or by lantern light at night. While old veterans might handle bees during the middle hours of the day at this time of the year, you certainly had best not try it.

Again, be sure that your honey, as fast as taken off, is put where no bees can get at it. If your honey is stored in a honey-house or honey-room, it is always safer to have it in such shape that, even should you or some one else leave the door open, the bees will be unable to gain access to the honey. If your honey is exposed in the room, and accessible to bees, some careless individual (most likely yourself) will forget and leave the door open. What follows, I need not describe in detail. Your first intimation of trouble is, that the bees are roaring in the air. The high key-note arouses your suspicions. Not greatly surprised, you step into the honey-house. In an open can of extracted honey you find about a peck of bees squirming in the honey. In one corner of the room is your section honey, uncapped, the honey which you had but yesterday admired and thought so nice. We have been in just these circumstances; and you, my dear beginners, are liable to get there too if you are not careful.

CLEAN SECTIONS.

We used both wide frames and T supers in our apiaries. While the filled sections from the supers needed little if any scraping, those from the wide frames had pretty heavy rings of propolis around the edges, and would require considerable scraping to get them in marketable shape. It is in just the crevice between the wide frame and the section that the bees seem particularly fond of depositing propolis. As Nature abhors a vacu-

um, so the bee abhors a crack. This, his instinct has taught him, must be filled up with his glue. The construction of the T super is such that the number of cracks and crevices is comparatively few. When sections from the T surplus arrangement and the Heddon crate come out so clean, it is a mystery to me why so many bee-keepers have to go and invent blanks in their section-crates, to cover the tops and bottoms of the sections. These blanks will form, when in contact with the sections, the nicest place for propolis to be secreted, and consequently thwart the object for which they were intended.

THE ALLEY TRAP AS A SWARM-CATCHER.

A correspondent wishes me to report my experiments with the Alley trap, as I promised last year I would do. In response to this request I will say that, just before the swarming season opened, I attached Alley traps to the entrances of a dozen or so of the strongest colonies in the Hyde apiary, of which I have made frequent mention. On all hives, whether portico or Simplicity, I found it necessary to secure the traps to the front of the hives, "toe-nail" fashion. I then directed the lady who was to watch for swarms, that, when one came forth, she was to fasten the trap (if the queen entered it) among the flying bees, on a rake. After being clustered, the bees were to be hived in the ordinary way. Some two weeks after, when I went down I saw that about half the traps, under the influence of the sun and rain, and the consequent shrinkage and swelling, had become partially detached from the hive — enough so to allow the bees to pass in and out, back of the traps. As queen-catchers, these, of course, were useless. Upon inquiry, Mrs. Hyde told me she had caught two swarms by placing the trap among the flying bees, and that the Alley trap, with these two, was a success. The other swarms, in consequence of the loosening of the trap, had to be hived in the good old-fashioned way.

FOUL BROOD TREATED BY CARBOLIC ACID.

In the treatment of foul brood recently we have been quite successful; and present indications seem to show that we are master of the situation. Our mode of treatment, as we now practice it, is as follows:

With a coarse comb—or, better, a wire brush—rake open all the brood-cells, whether diseased or not, in the affected colony. The bees will recap about half of it. With a weak solution of carbolic acid, spray thoroughly the bees, brood-frames, mats, and the inside of the hive. To make this solution, go to the drugstore and get some pure crystals of carbolic acid. Dilute this about three hundred times with hot water. When cold it is ready to use. In two days after the first uncapping and spraying, spray again, but do not uncap. In three or four days more, give them another dose, and so on till the bees have cleaned the "nasty stuff" out of the cells. Don't burn any more colonies until you hear from me again. I am experimenting, and do not wish to report the experiments in detail until next issue.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER,
MEDINA, OHIO.

TERMS: \$1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, AUG 1, 1887.

Brethren, if a man be overtaken in a fault, ye which are spiritual, restore such a one in the spirit of meekness; considering thyself, lest thou also be tempted. GAL. 6:1.

OUR subscription list now numbers 7592. Still gaining, you see.

THANKFULNESS.

We are, here at Medina, just now rejoicing on account of a drenching rain, followed up by small showers afterward. How is it with you, friends?

THE WEBSTER FUMIGATOR.

In speaking of the Webster fumigator, the editor of the *Revue Internationale*, published at Nyon, Switzerland, seems to have had an experience exactly similar to our own, as given on page 756, 1886. Our proof-reader translates a few lines:

With colonies of ordinary disposition, the odorous air, expelled by the bellows, suffices to repel the bees, and cause them to fill themselves with honey; but on those which are aggressive it has no effect, and the addition of a few drops of ammonia, even, is not sufficient to quiet them.

BLACK AND HYBRIDS QUEENS.

In our price lists we have given prices on these, but we also state that we can furnish them only when we happen to have them. Well, as there are no blacks or hybrids now in our vicinity, we prefer not to furnish them at all. We might buy them, it is true; but the prices are so low during the summer months it does not pay for the trouble of handling. Those who want them should send orders to the names mentioned in that department, to be found in every issue.

AN INVENTION WANTED.

FRIEND TERRY's article has suggested to me that the host of keen, sharp inventors among the readers of GLEANINGS might furnish a man who has the time and talent to make a dumb-waiter that can be put in any house in a few hours, and made to work all right. I have in mind an arrangement that can be loaded on to a wagon, a good deal as our pumpmen load up pumps, go in the house, cut a hole through the floor, put the machine in in good working order, explain to the housewife how to use it, drive on to the next house, and so on. I presume the whole thing could be boxed up and shipped like a bee-hive, with printed instructions, etc. Who will make it?

CARP-PONDS, AND HOW BROOK FISH GET INTO THEM.

THE above puzzling question is answered by Milton P. Peirce, author of the book on carp culture, and editor of the *Journal of Fish Culture*, Philadelphia. Friend Peirce says that various water-birds, in moving from one body of water to another in

the summer, may carry the spawn of different kinds of fish on their legs and feathers. Turtles, musk-rats, and various reptiles, may also do the same. The spawn hatches, and the little fish take possession. Birds that frequent bodies of water are, as a rule, very shy, and thus escape observation, which is one reason why we don't see them oftener. The matter is fully discussed in a recent number of the *Journal of Fish Culture*.

OUR SWAMP GARDEN.

WHILE every thing is parched up with the drought, it is refreshing indeed to have one little plot of ground that seems absolutely exempt from drought. This is our swamp garden. The celery looks as bright and fresh this hot, dusty July afternoon (the 29th) as if there had been a rain only yesterday. The Early Ohio potatoes, planted the 15th of June, were looking as bright and fresh as the celery, and more than knee-high, and they are just coming into blossom. This wet swamp was all transformed into this luxuriant garden by a single underdrain which is perhaps 18 inches below the surface. The plants all have their roots in moist, black vegetable mold; and without a particle of manure, almost all kinds of vegetables are just booming. So much for reclaiming one useless bog.

THOMAS HORN.

PLEASE remember, dear friends, that our offer in our last issue was to our *subscribers* only, who lost money by sending it to Mr. Horn. We can by no means undertake to make good such losses to people who do not care enough about our journal to pay the regular subscription price. Quite a number have asked if the amount might be applied on other goods than bees and queens. We have decided to allow it to apply on subscriptions for GLEANINGS, A B C books at retail prices, or to advertising space in our journal, or to bees and queens at our regular advertised prices, and the latter may be taken now or at any future time, as you choose. Another thing, friends: I don't think I have written any thing encouraging the idea that I propose to make good any thing more than the money sent to Mr. Horn, in answer to his flaming advertisement of bees and queens, express charges prepaid, etc. This advertisement appeared in GLEANINGS when it ought not to have been accepted. Of course, I have nothing to do with other dealings you may have had with Mr. Horn, in the way of hives, extractors, giving him advertising space, or things of that sort.

A FRIEND IN NEED IS A FRIEND INDEED.

Two postal cards, which read as follows, have made me feel quite happy:

MR. ROOT: I see you offer to pay Thomas Horn's debts, or a part of them, at least. I lost \$6.90 in cash by ordering queens and bees of him, but can not accept payment of you, as I can not see why you should pay his debts. I hope all the rest of the friends will feel as I do about it, and not ask you to pay.
Sae City, Ia., July 23, 1887. WESLEY CHENEY.

MR. A. I. ROOT:—I am obliged to you for offering to pay me the amount due from Thomas Horn. You may cancel mine, as I do not think you owe it. I think if Horn will let you pay his debts, he must have been from the start what you indicated.
Reading, Pa., July 27, 1887. IRWIN D. ALTHOUSE.

I am very much obliged indeed, friends, for your kind encouragement. As we do not all see things alike, however, I prefer paying those who think I am responsible for having inserted such an advertisement. Especially do I value your kind words, because there have been quite a few rather unkind words in regard to this very matter.

CURING FOUL BROOD WITH PHENOL.

IN view of what Ernest has written in this number, I feel as if I individually owed an apology to the friends both in our own country and across the water, who have remonstrated because we were stubborn in objecting to drugs for the cure of the disease. It has been mostly if not entirely my own fault. I told the boys that we did not want any drugs or medicine about our bee-hives. Well, although we are not at present prepared to say that phenol, or carbolic acid (which we suppose to be the same thing) is a positive cure for foul brood, we have done enough to settle the question, I think, that it has a decided effect on it. Ten or fifteen colonies of the worst cases we have had in our apiary have had the disease arrested, at least for the time being. The bees cleaned out the diseased cells, and refilled them with good brood. This good brood has been found, however, in only a few cases, where the disease appeared in only a mild form. We have done this much, any way: We have proved that the acid, for the time being at least, kills the fungoid growth, and it seems quite evident that, when we get sufficiently acquainted with the method of using it, it may prove to be an entire remedy. Destroying infected colonies by fire is at best a slow process; and with large apiaries like ours it is a question whether it will kill it out. Where a whole colony, however, is thoroughly sprayed with the diluted acid, we are inclined to think they will not communicate the disease to other colonies.

SPECIAL NOTICES.

GREEN'S SOLAR WAX-EXTRACTOR.

The solar wax-extractor mentioned in the last issue, is a substantial and well-built machine. It is the same as the one illustrated on page 28 of our price list. For the benefit of a few of our readers who have written about solar wax-extractors, we will say the price is \$3.00, with complete directions for using them.

GOODS FOR FAIRS AT A REDUCTION.

Inquiries begin to come in about prices on goods to be used for exhibition at fairs. According to our yearly custom we have decided to offer one each of the following articles at (25%) twenty-five per cent discount from highest catalogue prices, on the following conditions: viz.: 1. You must state in your order, as nearly as possible, the time and place at which the fair is to be held (and send us a premium list if possible), where you are going to exhibit the goods; 2. You will agree to distribute judiciously among bee-keepers, and those likely to become such, the catalogues and sample copies of GLEANINGS we send along with the goods.

A B C's of Bee Culture—all you can sell.

Bee-brush—either kind.

Alley's drone-trap.

Bee-entrance guard.

Bee and queen cages.

One pound of comb foundation of different grades.

Comb-foundation machine.

Purker's and Gray's foundation-fasteners.

Wire-imboder.

Honey-extractor.

Gray's or Simplicity feeder.

One of any style of hive we advertise, put up complete.

Perforated zinc honey-board.

One box of 500 sections.

Clark's smoker.

Solar wax-extractor.

THE OUTLOOK FOR HONEY.

Notwithstanding the fact that the new crop of honey is already on the market, we have disposed of more old honey within the last two weeks than we had sold six months previous; consequently our stock of old comb honey is nearly cleaned up. We still have on hand a large quantity of extracted honey, especially of California sage. We are selling this, and basswood in cases of 2 cans containing 60 lbs. each, at 7 cts. per lb., and clover at 8 cts.

Single can lots, at 7½ and 8½ cts. per lb., respectively. Small samples free on application. Prices are advancing all around, owing to the scarcity of the present year's crop, and we may advance in the near future.

CONVENTION NOTICES.

The Stark Co. Bee-keepers' Society will hold its next regular meeting in Grange Hall, over Farmers' Bank, at Canton, O., on Tuesday Aug. 9, 1887. Mark Thompson, Sec.

FOR SALE

An 80-acre farm in Franklin Co., Ill. About 60 acres in cultivation. 2 good wells, ½ mile from school, 3 miles from P. O., 5½ miles from Co. seat. For particulars as to price, address John W. Lillie, Ewing College, Ill., or to me here. 15rfd

JOHN A. LILLIE, Raton, Colfax Co., N. Mex.

FOR SALE OR TRADE.

12 colonies of Italian and Holy-Land bees in Root's chaff hives, 12 colonies in Heddon's hives. Free on board cars here. Hives new and well painted. All combs on foundation in splendid shape. If you have any thing to trade write me at once. 15rfd

S. C. KIRKPATRICK, Hodgenville, Ky.

UNTESTED DAUGHTERS FROM ONE OF Doolittle's best queens, only 50 cents each. Tested queens, \$1.00 each. 15rfd

I. R. GOOD, NAPPANEE, IND.

PURE ITALIAN QUEENS

—FOR 1887.—

Tested, \$1.00; Select tested, \$1.25; Imported, best, \$5.00. All my queens are reared by natural swarming now, and sent out by return mail. Write me for low prices on two and three frame nuclei with any of the above queens in each. Address

S. F. REED,

N. Dorchester, N. H.

PASTEBOARD BOXES

FOR ONE-POUND SECTIONS OF

COMB HONEY.

THIS box has a bit of "red tape" attached to it to carry it by. It makes a safe package for a single section of honey for the consumer to carry, or it can be packed in a trunk, if he wants. It can be opened in an instant. The price of the box is 2 cts. each, set up; in the flat, 15 cts. for 10; package of 25, 30 cts.; \$1.00 per 100; or \$9.00 for 1000; 10,000, \$80. If wanted by mail, add \$1.00 per hundred for postage. Colored lithograph labels for putting on the sides, two kinds, one for each side, \$3.00 per 1000. A package of 25, labeled on both sides, as above, 50 cts. By mail, 30 cts. more. They can be sold, labeled on one side or both sides, of course. We have only one size in stock, for Simplicity sections. Sample by mail, with a label on each side, 5 cts. If you want them shipped in the flat, labels already pasted on, the price will be ten cents per hundred for putting them on.

Your name and address, and the kind of honey, may be printed on these labels, the same as other labels. The charge for so doing will be 30 cts. per 100; 250, 50 cts.; 500, 75 cts.; 1000, \$1.00.

A. I. ROOT, Medina, Ohio.

Stanley's Little Gem.

An Automatic Honey - Extractor
FOR ONLY \$10.00.

A NEW MACHINE, AND JUST WHAT IS
WANTED BY THE MASSES.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens
which they want to dispose of, we will insert notices free of
charge, as below. We do this because there is hardly value
enough to these queens to pay for buying them up and keep-
ing them in stock; and yet it is oftentimes quite an accommo-
dation to those who can not afford higher-priced ones.

I will sell a few hybrid queens at 50 cts. each.
Safe arrival guaranteed. L. B. BELL,
Brecksville, Cuy'a Co., O.

I have some fine mismatched Italian queens to sell
at 50 cts., or I will exchange for a honey-extractor.
Satisfaction and safe arrival guaranteed.
MARKWOOD JERVIS, Maumee, Lucas Co., O.

I am requeening my apiary, and will sell hybrid
queens for 40c apiece, or 3 for \$1.00. Wing clipped.
GEO. L. FERRIS, Five Corners, Cay. Co., N. Y.

I have a few good prolific hybrid queens for sale
at 40 cts. each. I will also sell black queens at 25
cts. each. Satisfaction guaranteed.
FRED LEININGER, Douglas, Putnam Co., O.

I have 40 good hybrid queens (with clipped wings)
for sale at 35 cts. each; four to one address, \$1.00.
Queens raised in 1886. GEO. H. DENMAN,
Pittsford, Hillsdale Co., Mich.

Hybrid queens for sale at 50 cents each.

HONEY COLUMN.

CITY MARKETS.

ST. LOUIS.—*Honey*.—We quote choice comb 10@12 cts.; latter is for choice white clover in good condition. Strained, in bbls., 4@4¼ cts. Extra fancy, of bright color and in No. 1 packages, ¼ cent advance on above. Extracted, in bbls., 4½@5½ cts.; in cans, 5½@6 cts.

Beeswax, 21 cts. for prime.

Market very firm at above prices. Owing to the short crops reported everywhere, we look for a still further advance in prices.

Aug. 2. D. G. TUTT & Co.,
206 N. Commercial St., St. Louis, Mo.

KANSAS CITY.—*Honey*.—We quote new crop:
Choice white 2-lb. sections, 14
Dark 2-lb. sections, 11@12
Choice white 1-lb. sections, 16@18
Dark, 1-lb. sections, 12@14
California, 2 lb. white, 14
" 2-lb. extracted, 12@13
Extracted, new crop.
Choice white, 8@10
Dark, 5@7
California white, 8
" amber, 6@7

Beeswax, 20@22. Crops of 1886 exhausted.

July 28. HAMBLIN & BEARSS,
514 Walnut St., Kansas City, Mo.

ST. LOUIS.—*Honey*.—The old stock of nearby honey is well cleaned up in this market and we look for better prices on new crop, which, from our information, will not be over 60% of last year's crop.

We quote: Choice new white-clover honey, 1-lb. sections, 12½; good fair stock, 10@11. Extracted, cans, 6@7; bbls., 5@5½. Southern honey, extracted, bbls., 3½@4½. *Beeswax*, 21. Demand good.

W. B. WESTCOTT & Co.,
Aug. 10. 108 and 110 Market St., St. Louis, Mo.

NEW YORK.—*Honey*.—Honey has not commenced to come into this market yet, but if the present cool weather continues, we may expect shipments very soon. We quote, until prices are better established, fancy white 1-lb. sections 15@16
Off grades 1@2c per lb. less
Fancy white, 2-lb. sections, 12@14

Beeswax, 22@23.

Aug. 11. MCCAUL & HILDRETH BROS.,
25 and 30 West Broadway, New York City.

CLEVELAND.—*Honey*.—The market looks better than for several years. Choice 1-lb. sections of white honey sell as fast as it arrives, at 16c; 2-lbs. 14@15. Second grade, 13@14, but slow. Extracted 4@6. *Beeswax* 25.

A. C. KENDEL,
Aug. 9. 115 Ontario St., Cleveland, Ohio.

CHICAGO.—*Honey*.—Offerings light, yet sufficient to meet the demand, as the higher prices asked keep out speculations, few believing that it will touch any higher figure. The best grades white comb, 17 c in 1-lb. sections. Extracted, 5@8 per lb.

Beeswax, 22c. R. A. BURNETT,
July 21. 161 So. Water St., Chicago, Ill.

DETROIT.—*Honey*.—No new honey in the commission houses, and but little has been sold. All the city papers continue to quote it below actual prices received. Best white has sold from 12¼@14c.

Beeswax, 23c. M. H. HUNT,
Aug. 10. Bell Branch, Mich.

KANSAS CITY.—*Honey*.—A few cases new honey in market; 1-lb. comb we quote at 16c; no extracted. *Beeswax*, 18@22.

CLEMONS, CLOON & Co.,
July 30. Kansas City, Mo.

PHILADELPHIA.—*Honey*.—Honey not wanted yet, and unsalable.

Beeswax, quiet: Choice yellow, 22@23
Inferior dark, 20@21
White, 26@28
Aug. 10. PANCOAST & GRIFFITHS,
Philadelphia, Pa.

BOSTON.—*Honey*.—No change in honey.

BLAKE & RIPLEY,
Aug. 10. 57 Chatham St., Boston, Mass.

WANTED.—All the bee-men who see this adv't to send us one hundred pounds of 1-lb. and 2-lb. sections of white comb honey, as sample, by express, stating quantity, and price for same, cash, delivered in Kansas City, Mo. CLEMONS, CLOON & Co.
15-16d Cor. 4th & Walnut St's.

WANTED.—To purchase from one to five thousand pounds choice white-clover honey in one-pound sections. Crates to average about 25 lbs. each.

I. T. CARSON & Co.,
325 West Main St., Louisville, Ky.

FLAT-BOTTOMED FOUNDATION.

FRIEND W. Z. H. DECIDES AGAINST IT.

I AM inclined to agree most thoroughly with Dr. Miller upon this subject. Two or three times, in different years, I have experimented, in a small way, with flat-bottomed foundation, by filling alternate sections with that and the other alternates with Given. This same digging of holes, and tearing-down of the edges near the top of the foundation, always appeared unless it might have been during the height of a good honey-flow; and even then the bees would often gnaw and pull down one edge, so that the opposite edge would strike the side of the sections, and thus give the foundation a kink. I must admit, however, that, when the combs were finally finished, but few of these imperfections showed. The greatest objection I had against the flat-bottomed foundation was, that the bees drew it out more slowly, and did not finish up the sections as quickly as they did those having Given foundation; but my neighbors, Doane and West, used the flat-bottomed exclusively, or nearly so, and were so enthusiastic in its praise that I finally thought that perhaps the bees didn't like it so well; but when they had no Given by its side, with which they might make unpleasant comparisons, they might be better satisfied, and would work accordingly; and, as a result of my cogitations, I used the flat-bottomed this year exclusively. I wish now I had not. I wish I had used one-half Given. My experiments had hitherto been too much of a one-horse character, a class of experiments in which my faith is somewhat limited; and now, when I used the flat-bottomed foundation upon a large scale, I neglected to use any other with which to compare it. I feel like kicking my-

self every time I think of it. The faults I have mentioned were just as observable, however, and I believe I received less honey by its use, but I do not know it, and can not prove it. That the bees change the base of the cells, there is not a particle of doubt; and that the "fish-bone" is reduced to a minimum is also true, and that more sections can be filled with foundation for less money is another fact; but that all this puts more money into our pockets remains to be proved. All things considered, no foundation has given me the satisfaction that has the Given. I shall, however, use flat-bottomed foundation again another year, and I shall try to use it in such a manner as to enable me to prove something.

CLAMP WINTERING.

You, friend Root, ask if I am satisfied now just where the cause of my former failures lay, in wintering bees in clamps. Friend R., that word "failures" should be used in the singular, as I have met with only one failure since I began wintering bees in clamps several years ago. That failure was caused by putting too many in one pit and burying them too deeply. No, I do not think a clamp any safer than a good cellar, and I have continued the practice more for the desire of proving it a success than for any thing else. Yes, friend R., I have taken into account the difference in localities. I am speaking of my locality. Upon this point, please allow me to quote from a recent article of mine in the *A. B. J.*: "As we approach the equator, less protection is needed by bees, and finally a point is reached where chaff hives and cellars never come. Before this point is reached, however, there is another point where some protection is needed winters; where chaff hives and the various kinds of packing are probably a sufficient shield against the

cold; and by means of which our bees can be wintered to better advantage, and, it is likely, with no greater consumption of stores, than in a cellar.

W. Z. HUTCHINSON.

Rogersville, Genesee Co., Mich.

Friend H., you speak of the Given foundation continually, but say nothing of that made by *rolls*; but I believe the latter is the kind generally in use the world over. If I am not mistaken, even Heddon, although so enthusiastic on the Given foundation at one time, has abandoned it; and, by the way, I don't believe he has ever told us just why. Will he please speak out? If I am not mistaken, a good many others who formerly used the Given foundation-press have *given* it up; and, in fact, at present there are no more Given presses made, that I know of. If I am mistaken, I expect, of course, to be corrected; but if I am not, why confine your remarks to flat bottom and to Given, or do you mean us to infer that the Given is so near like that made on rolls there is practically no difference? You say more sections can be filled with foundation for less money by using flat bottom. I think, if we try hard, we can make as many square feet to the pound as anybody wants, and with natural base; but friend Miller and some others think they don't want foundation running more than, say, about 12 square feet to the pound.—In regard to clamp and cellar wintering, I believe we now entirely agree; but with the experience I have had with the climate of Medina County, O., I should say we don't want our bees in clamps or cellars. Others may, however, like cellar wintering, and succeed best with it, even here.

HOUSEHOLD CONVENIENCES, ETC.

DR. C. C. MILLER TALKS TO US ABOUT CUPBOARDS, HANDY TABLES, AND OUTDOOR AIR FOR THE MOTHERS AND DAUGHTERS.

THREE or four years ago I put in my leisure time one winter at a bit of carpentry. At the back end of the house was built on an addition for a summer kitchen. Then this was prolonged to make a honey-room, with no partition between the honey-room and the kitchen. This winter of which I speak, I got some flooring and studs, and put up a partition between the kitchen and honey-room, also lined the walls of the kitchen with flooring, and ceiled it overhead with the same. Then on one side of the kitchen I built a cupboard that occupied all the room I could get between the corner of the room and the door, making the four cupboard doors run within an inch of the floor, and within 3 inches of the ceiling. This made a cupboard 8 ft. long, 9 ft. high, and 1 ft. deep. It is quite common to let a cupboard run to within perhaps two feet of the ceiling. This makes just so much space about wasted, sometimes worse than wasted, for it is merely a place to catch dirt. Better let it run clear to the ceiling.

The cupboard whose contents were to be removed to this kitchen cupboard had shelves far apart, measuring from 10½ to 14 inches in height. Instead of taking this for a pattern, I measured the actual depth occupied by the articles on the different shelves, and made the new shelves just far

enough apart for their accommodation. Commencing 31 inches above the floor, leaving this space to set and hang different articles, I made the shelves from 6 to 14 inches in height, thus giving me 8 shelves instead of 4, as in the old. Now, there is nothing remarkable about this kitchen or cupboard. Any bee-keeper handy with tools could do the same work; but taking the two together, and my wife would rather give up any other room in the house. She says that I can not realize how many steps are saved by the present arrangement. Formerly the dishes had to be carried through the dining-room to the kitchen, and back again to the pantry, but now they are lifted from the cupboard to the table and from the table back to the cupboard, with scarcely a step between. We bee-keepers are great for planning about our bee-work. If we had the housework to do, don't you think we should plan some to make the work lighter? and can we not do the planning, even if the queens, and not ourselves, do the work?

One day, on account of sickness, if I remember rightly, I undertook to skim the milk. There was no room on the shelves to skim it, and I had no choice but to set it on the floor or carry it out into another room. Next day I ordered a light table made to set the milk on for skimming; and yet, for aught I know, it had been needed just as much for years. It only shows that I was not as observing as I should have been. It occurs to me that, from what I have said above, some one may infer that we generally eat in the kitchen. The inference is an entirely correct one. When we have company we can use the dining-room; but for our little family the kitchen is plenty large; and although home made it is nicely papered, so that it looks as good as if bought out of a carpenter-shop. I much prefer to eat there, and thus save work.

And now I have a conundrum to propose, to which I should like one or more answers. What can be done in winter time to give to the women-folks a regular outdoor airing every day? I don't mean those who can afford to ride out every day. That may do for some, but for most it is not convenient, if not impracticable. And yet it is a serious matter for a woman to stay indoors day in and day out, and hardly ever get a sniff of outside air. Is there any thing they can be called upon to do, in the way of some appropriate duty that will oblige them to be outdoors regularly a certain length of time each day? They can bring in wood and water, but in many cases that is too hard work; and yet, since studying upon this question, it does not worry me as much as it formerly did to see a woman lugging in wood on a cold winter day. My wife having been brought up on a farm, she has quite a taste for poultry; and by careful selection had built up a beautiful flock of Plymouth Rocks. I succeeded in convincing her that there was no particular profit in them; and as it interfered with the bee-work she very reluctantly consented in the fall to give them up the next spring. In the winter, however, I found she spent so much time pleasantly outdoors with the hens that I changed my mind and concluded it was profitable to keep them. But all can not keep hens. What can they do? C. C. MILLER.

Marengo, Ill.

Friend M., if you had gone into the pantry when at our house, and used your eyes, you would have seen exactly the arrangement you mention—a cupboard opening into the

pantry on one side, and into the dining-room on the other. In regard to using the kitchen for a dining-room, we often use the pantry for meals; and it is always in the pantry that I get my supper Sunday evenings, after prayer-meeting. I rather enjoy it, too, for the room is so small we eat by twos, and Sue and I are generally the last two, so we have a little bit of Sunday evening alone by ourselves, just as we used to have a bit of Sunday evening all to ourselves about 25 or 30 years ago.—I agree with you in regard to the outdoor business. Let the women and everybody else have something to call them outdoors regularly every day all winter long. Poultry is certainly one of the best industries. A carp-pond close by might tempt them out to slide and skate, and I believe my wife would beat any of her girls in sliding, even now; but I fear that she wouldn't want to stay on the ice long enough to put on skates.

CUBA, AGAIN.

FRIEND OSBURN TELLS US SOMETHING ABOUT THE GREATEST YIELDS OF HONEY.

FRRIEND ROOT:—You wish to know what was our greatest yield from any one colony, and about how much said colony in its best days stored in one day. It would be impossible for me to give you a statement or record of what any one of our colonies did last winter; for my little son and myself being alone it was all we could do to take the honey as fast as it came in, and do what other work there is connected with the harvesting of a crop. But I can give you the result of one colony's work for 59 days while I was at San Miguel, three years ago this winter. Hive No. 423, from the 31st of December until the 27th day of February, stored 620 lbs. of honey. The yield per day was nothing to what colonies have been known to store; but taking the whole fifty-nine days, the amount secured will compare favorably enough with other large yields; for, in truth, it is a big yield. If my health is spared me, I shall take one more honey crop in Cuba (this winter), then I shall return to California; for my obligations to my children will not admit of my keeping them here any longer than this winter. I expect to be obliged to leave Cuba with a cherished ambition unsatisfied; i. e., taking from a given number of colonies (say 100) 500 lbs. to the colony. I think it is possible; and had it not been for the many ifs in the way last spring, my son being taken sick on the 7th of March, and the large increase we wanted to make (420 colonies from 80), I am satisfied I should have realized what I wished to; that is, 50,000 lbs. from 100 colonies. This winter our apiary will be so large that it will be quite impossible to keep the honey of any one colony or number of colonies separate.

Speaking a little further about large yields from single colonies, that system of reporting is wrong. While there may not be any injustice intended, it is apt to put too glowing a face on bee-keeping for a beginner, while the veterans know that such results are possible only when all conditions are favorable. You and I, Mr. Root, have been in the business some time, and we know that, when a colony fills their top combs every week (say 50 lbs.) week in and week out, it is good business, and there

are more colonies that will not do it than there are that will. But in an experience of many years it has not often happened that we have met with the exact combination for such large yields in individual colonies, and I am compelled to say that, when we have, it has always been hybrids.

Yes, I have used grass in the nozzle of my smoker, but I do not know that I got the right twist to it, for it never gave very good satisfaction. It would soon burn out, and the ashes and partly burnt grass would all be blown in the hive, which would cause the bees to make faces at such treatment; but I have much faith in the sawdust for fuel, although I have never tried it. I think, if it is pressed down hard, and dampened a little, it would work nicely. I will add one word more about burning green wood. After the smoker has been burning a spell and wants more wood, I press to one side the wood that remains in the smoker, and is partly burnt, and put the green sticks in the other side. That keeps the fire and charred wood close together; and by the time it is burned out, the green will be seasoned and burning too.

BEES MIXING.

I told you in my last article how close our hives sit to one another. Well, many of them are very strong, and, under the influence of this Cuban climate, lie out on the front of the hive, the alighting-board, and on the ground, and they mix and mingle together, until it would seem that they were all one family. Do they quarrel and fight? No, they seem to have a good time of it—a sort of old-fashioned quilting or husking bee. Whether they go into one another's hives or not, I can not say; but one thing I do know—they are not bad enough, under such circumstances, to kill another fellow's mamma.

PAINT.

After trying many of the mixed paints and white lead, we have at last settled down on zinc as giving us the best satisfaction.

GLEANINGS.

One word as to its being an "all-around journal." I think no well-balanced mind can find any fault with the make-up and the matter that grace its pages from month to month; and the subject, "The Water We Drink," I have been deeply interested in. I fully agree with you and Prof. Cook in what you say; and the article contributed by Geo. Thompson is worth more than the price of GLEANINGS for one year. It contains so much substantial good that every man, woman, and child should read it. It is just what I am heart and soul interested in.

THE WATER WE DRINK.

After three years' living here, my children and myself put up with water as best we could, such as comes from open wells, that the oldest man could not remember the time when they were cleaned, and from springs that run through pastures, and were the receptacles of decayed vegetation. I suggested to Mr. Dussaquet that we have a bored well of our own, and we had it. Need I tell you it is a bigger prize than was ever drawn at the Havana Lottery? The soil here is a stiff hard clay. After going down 20 ft. in this clay we struck water, pure and unadulterated. The hole is 2½ inches, and a 2-inch pipe put down, with a good pump. I will tell you how it is fixed around the top, to exclude surface water. For about 3 ft. from the top down, the hole is six inches across. We first began filling in around the pipe at the bottom of this 6-inch hole

with new sacking (gummy sack), tamping it down hard, then clay, to within one foot of the top; then water-lime, made into a stiff mortar, and rounded up around the pipe until it seems impossible for one bit of water to get in, or not until it is well filtered, at all events.

One word about sinks, slop-holes, and water-closets. A sink with a drain or a pipe to it I could never have about the house; the same with old slop-holes; and as for the water-closet with the old-fashioned pit under it, that would have to take itself off the premises with the old filthy pipe of the sink and slop hole. All these three abominations can be dispensed with, and are, I think, among our most intelligent people of to-day. A. W. OSBURN.

Havana, Cuba, Aug. 5, 1887.

Thanks, friend O., for your excellent report in regard to Cuba, and the immense yields of honey you get there. You failed, however, to tell us how much you received per pound for your great crops; and that, you know, would be quite an interesting item in securing the 50,000 lbs. from 100 colonies.—Thanks for your suggestions in regard to drilling for water; and I hope we may all of us come up to your concluding remarks. I don't see, however, the harm that slops may do if carried into the garden, even by pipes properly arranged so that the roots of growing plants may absorb the fetid matter.

DOCTORING WITHOUT MEDICINE.

A REMEDY FOR NERVOUS PROSTRATION.

I HAVE before told you something of my experience with nervous exhaustion when overworked mentally; and I hope, dear friends, you will bear a little with me in talking about my ailments, so long as I can tell you how I have triumphed over disease. When business is up to its highest notch, say just preceding or during the honey months, I almost always break down, or come pretty near it. At such times there are three things that usually wind me up and set me going. One is a good square meal; the second is getting out of the office and going out into the open fields, and the third is sleep. I have been in the habit of getting strength by either of these three methods which is most convenient. The fields cause me to neglect work, so I often push through my tasks as well as I can until dinner-time. If dinner does not restore me, a great many times I am obliged to go home and take a nap to keep from breaking down altogether.

Well, I noticed a good many times that, when I pushed ahead until dinner-time, by the time I was seated at the table I was so much exhausted that I felt like grasping a glass of milk, or something else nourishing, much as an intemperate man would reach for his morning dram before he could steady his nerves so as to dress himself. In fact, I would often sit down to a meal all in a tremor, and with a dizzy faintness. Usually I felt tolerably well about the time my meal was finished. Sometimes, however, I didn't get level, if that is the right expression, until half an hour afterward. At such times, although I had excellent dinners, they didn't

seem to sit just right. During the past summer I have felt great relief by taking a nap each forenoon or each afternoon; and finally I began to notice that, when business crowded so that these naps came just before meal-time, I could sit down at my meals without the symptoms of exhaustion I have mentioned. Then it occurred to me that Dr. Salisbury, of Cleveland, O., used to urge and almost insist that I should never eat a meal without first being rested thoroughly for twenty minutes or half an hour on a lounge or bed. He said it was far better to have a good sleep before eating; but if I could not sleep, lie still without sleep. My wife has urged this very point for years; but I have usually been so busy just before meal-time I could not get around to it. For some time back, however, I have been taking just half an hour's sleep before dinner and supper; and if any sort of patent medicine had ever given me such a lift in the way of health, it would very likely have been "boomed" about as well as I could boom it. The philosophy of it seems to be this: If you want a man to do a good piece of work, he should be well fed and well rested. Yes, the same is true, even of a horse. Well, Dr. S. declared it was a task for a weak constitution to properly digest a meal of victuals; and he declared further, that no constitution could digest food properly when it was exhausted and run down to the very last notch; and if any one attempts to get along in that way he will sooner or later find himself broken down entirely.

Now, then, ye tired housewives, remember this: You are not saving time by sitting down to your meals, so completely exhausted and worn out that the hand trembles with fatigue that raises the food to your lips. You will get along faster, and accomplish more, by taking the kind of rest I have told you of. If it seems to you impossible, and you are inclined to smile at the idea of a half-hour nap before dinner and supper, then I shall direct my appeals to your husbands, your sons, and your daughters. As you value the life and the presence of this patient, hard-working mother, make her take that needful rest, just as my wife and children have been making me use the good common sense God has given us all.

SHIPPING QUEENS IN THE PEET CAGE.

TROUBLE WITH THE GOOD CANDY.

I HAVE had trouble with shipping queens in the Peet cage, with the "Good" candy, and also have in mind the experience of another breeder who had similar trouble. With the best of care, sometimes a whole shipment would arrive dead. Probably only those who have had such experience know how discouraging it is. I now make the candy pretty thin (granulated sugar will do to make it with), and put a sufficient quantity of it in a small piece of cheese-cloth, and press it into the "feed-hole" and then put a sponge filled with sweetened water in the other. I do not generally put more than six bees into the cage and they can suck all the "juice" they need, out through the

cheese-cloth. I have had as perfect success, since using this plan, as I could desire, and I have mailed them quite far. I am indebted to Mr. G. D. Black, Brandon, Iowa, for the idea. C. WECKESSER.

Marshallville, O., Aug. 8, 1887.

I feel quite certain, friend W., that the trouble is somewhere with your candy. If you have noticed what we have said in reference to the matter, you will see that we insist on using only powdered sugar, or granulated sugar powdered up with a hammer, or, better still, a pestle-mortar, to a smooth powder. This will hold honey so the bees can get it, and they will eat it, honey and sugar both, and it can not possibly daub them when placed in Peet cages. We have tried almost all methods in the way of sponges, water, etc., but our success with the Peet cage and the Good candy is so much better than with any other arrangement we think we shall stick to it, and we use these cages by the thousand, as you may know.

OUR P. BENSON LETTER.

G. U. S. & G. B. B. S. M. CO.

JAN. 17.—In yoonyun there is strength. Wherefore I hev combined myself with four (4) uthers for the purpuss of maniafacturin bee-supplies of oll descriphsens. At a meetin of the stock-holders to-day the followin offasirs was elected:

P. Benson, A. B. S., President.

J. F. Wilsen, Vice-President.

W. T. Hutch, Seckitary.

C. Mills, Tresharer.

The Board of Directers is me and Jack Wilsen and Will Hutch and Charlie Mills and Gordus Stull.

The tightel of the corporashen is the Grand United States and Grate Britten Bee-Supply Maniafacturin Co. Thay was a fool meetin of the Board to-day.

MEETIN OF FOOL BOARD, JAN. 17.

JAN. 29.—Bizniss of the G. U. S. & G. B. B. S. M. Co. is jist a boominn. Met Will Hutch the seckitary, to-day and he toald me a order hed cum for a bee-vaile with 50 cents in postage stamps; and what shoold he do with the stamps. I took them and poot them in my pawket. A bird & a hand is worth 2 & a bush.

FEB. 1.—A stormy seshun of the board to-day. Charlie Mills, refurrin to the postage stamps, intimidated that I hed embezzelled the funs of the company, by takin them stamps in a syruptishus manner. I kindly but firmly informed him that his reesignashen wood be excepted. He retortured that me and the cumpenny cood go to thunder;

and with that he woektt off, and that was the last of him. Charlie alwaze was rather ruff, but then he never hed enny bringin up. The ballence of the seshen was harmoanuss.

MARCH 7.—To-day we got a order for a swarm of bees. The board met to consult whare to git the bees. Ole Miss Hoover, she that used to was Feby Roadman, hed 2 swarms and was handy by, but she wanted the pay rite down, so we cood do better to by of Scotch Marget, who was a mile and a ½ out. Me and Will Hutch was deputized to go after the bees, and we was to go next day at nite. Next mornin Jack Wilson cum over to git me to help bild a tirky-coop for Mary. Her tirkys kep a stray-in off to Perry Davuses. I told him I wood if heed take my place to go after the bees. So in the even-in him & Will Hutch went for the bees. Jack stood off at a respectable distants (he's ruther moddest) and gave instruxyens whare to plug up the bees. When all was sekewered thay started. The very 1st stop, Jack sez, sez he, "Thare's a loose bee, Will," and with that he dropt the hive and lit out, a pawin the wind with both hands. The minnit he dropt the hive, the bees begins to pour out onto Will, and with that Will gits mad and ups and kicks that thair hive into 10 thousand peaces. Will alwaze was a leetel hi in the temper. Naterrally thay was both mad, Will blamin Jack for droppin the hive, & Jack a blamin Will for not shuttin them up titer; and when I woodent take sides with both of them thay rezined.

MEETIN OF FOOL BOARD, MARCH 8.

MARCH 8.—To-day Gordus Stull told me I hed ot to of gone myself for the bees, bein president; & I wurd brot on another, & I woodent stand it & discharged him on the spot. Its all the better. Thair will be less chants for dessenshun in the board.

VENTILATING BEE-CELLARS.

Are We Sure They Need It?

DO WE WANT BEES IN A CELLAR AT ALL IN OHIO AND OTHER SIMILAR LATITUDES?

ON page 567 friend Hutchinson says: "Where is the man who *knows* that sub-earth ventilation, or *any* ventilation for a bee-cellar, is needed?" It is not very safe for me to be very positive about any thing that I think I know about bees, as there are so many chances to be mistaken; but I feel about as sure of the need of ventilation as I do of almost any of the points of bee culture with regard to which Bro. H would not call my knowledge in question. I do not suppose that, in the strictest sense of the word, W. Z., or, indeed, any one, doubts

the need of *some* ventilation. Bees, I suppose, never go through a winter without respiration; and for this, at least a small amount of air must from time to time be changed. But without any hair-splitting, I suppose those who claim no ventilation is needed, mean that we need take no pains to secure the very little that is needed, and that even through the walls of a hive may come that little, and in the closest cellar enough air will be forced through the little crevices to supply all needs.

I think it is true, that no cellar is made so tight but that, if the cellar is warm enough, some little change of air will be constantly taking place. Years ago I wintered 8 colonies in a cellar which was as tight as I could well make it. In ordinary language, the cellar had no ventilation whatever. Those colonies came through in the finest possible condition, and I suspect that many a man with a like experience draws the conclusion that no ventilation whatever is needed. He is right so far as he is concerned, for the little air forced through the cracks of the cellar is enough for the few colonies. But when I put 200 colonies or more in that same cellar, the case was materially changed. I made some provision for ventilation by providing exit through chimneys for the exhausted air. In the coldest weather this was generally sufficient. The bees at times became uneasy and noisy, the noise gradually increasing, and I concluded the bees were too cold. I put a wood fire in the cellar in the afternoon, letting it die out in the evening, and in the morning I found the bees perfectly quiet. This was done many times, and always with the same result. But, one thing puzzled me: Go into the cellar the morning after firing up, and finding the bees quiet, I nearly always found the thermometer standing just where it did before I put in the fire. I asked myself the question, "If the bees were noisy yesterday because the thermometer was at 40°, why does not 40° make them noisy today?" I finally concluded that the fire had increased the change of air, and the bees were quiet, not because warmer, but because they had better air; and to this day I have found no better answer to the question. The air is changed in a cellar, because the outer air, heavier because colder, forces its way into the cellar by means of its greater gravity to displace the inner, or warmer air. The greater the difference between the temperature within and without, the more rapid will be the ventilation. Now, suppose a warm spell comes toward spring, when the thermometer stands at 45°, out and in. These are the trying times; for the air, being of equal density without and within, ventilation ceases. At such times the bees become very noisy; and as soon as it is dark I open all windows and doors. Upon this the noise greatly increases; and to one hearing it for the first time it is something alarming. By morning, however, all is quiet, even if the bright sun is shining in the entrance of the hives. Now, on what other hypothesis can this be explained, than that the bees needed ventilation, and were quiet when they got it?

And now let me ask friend Hutchinson, "Where is the man who knows that ventilation for a bee-cellar, or, indeed, for any cellar, is *not* needed? Didn't you think it was needed when you put the wooden tube in your clamp? or did you have the tube solely to let down the thermometer? Admit the need of ventilation, and sub-ventilation is easily proven necessary in cold localities until some

cheaper way is found to provide fresh air at a sufficiently high temperature.

Mr. Root thinks it better, all things considered, to winter outdoors, and I think he is right. I think it better to winter in cellar, and I think I am right. But the climate of Marengo is not that of Medina.

Now, I should like to ask you, friend Root, why do you think your bees winter better out of than in the cellar? It can hardly be temperature, for you can secure any temperature desirable in the cellar. Is it because of the light? The cellar can be made light; and I may remark, in passing, that, if ever perfection is reached in cellar wintering, it is possible that no effort will be made to secure darkness. Do you prefer outdoors because bees have a chance to fly through the winter? This can be evened up by taking out the bees and giving them a chance to fly every time the outdoor bees fly; but nearly every one objects to this taking-out as unnecessary, if not injurious. I suspect that, in the final analysis, it will be found that the main difference is, that, outdoors, the hive is at all times surrounded by a pure atmosphere. But, friend Root, please say what *you* think is the why.

I think many of us will thank the editor for the useful hints in chapters 37 and 38 of "What to Do," and I thank you for calling attention to cerealine, which I had never before tried. It is a nice and convenient food; only are you not mistaken about five pounds for 16 cents? It costs more than twice as much here.

C. C. MILLER.

Marengo, Ill., Aug. 9, 1887.

Friend M., you have given me at least one new idea in the above, and it is in regard to the very question you asked me to answer. The great trouble in cellar wintering was where we had a good many colonies in one cellar, and when the temperature outside was about the same as inside. At such times the bees were uneasy, and the air in the cellar was very bad and close. I know the cellar at such times needed ventilation, not only for the good of the bees, but for the good of the people who lived over the cellar, and I tried to get it by opening the doors and windows during the night time. This made matters better, but it did not remedy the difficulty. With your explanation, I now believe it was because even the doors and windows didn't ventilate the cellar fully when the temperature was about the same outside as inside, and little or no breeze was stirring. Sometimes we have warm foggy spells here in February, and I have seen them even in December and January—yes, a whole week without a bit of frost. At such times I don't want bees in a cellar; and in regard to taking the bees out for a fly when the bees fly outdoors, this would be entirely out of the question, for most winters our bees have a good fly every month in the season.—In regard to the price of cerealine, Ernest made the purchase, and insisted he got 5 lbs. for 16 cts. Investigation shows, however, that the package held only 2 lbs. instead of 5. As the article is very light, even 2 lbs. makes a great big package, and I think it is a boon to humanity, even at 8 cts. per lb. I may remark that it costs 14 cts. per package at wholesale in New York. Possibly the price might be got down a little by buying in large quantities of the manufacturers.

A NEW BEE-ENEMY.

PROF. COOK TELLS US OF ANOTHER CURIOUS INSECT.

MR. W. J. ELLISON, of Stateburg, S. C., sends me a bug which sucks the blood and life from his bees. As I have never heard of this bug as a bee-enemy, I am much interested in it. Indeed, I knew of only one bee-killer among the bugs proper, before this one came; that is, the curious stinging bug, *Phymata erosa*, Fab., which is fully described and illustrated in my Manual, last edition, p. 322. This new bee-stabber—I will christen it the bee-stabber—as Mr. E. says it stabs the bee and sucks it dry—is known in science as *Euthyrhynchus Floridanus*, Linn. As would be inferred by its generic name, it has a very powerful four-jointed beak, which is shown magnified in the figure. From the specific name given by the great Swedish naturalist, Linnæus, we should expect it to occur in Florida as well as in South Carolina. Probably the one described by Linnæus came from Florida. This insect was also described by Th. Say, as *Pentatoma emarginata*. His description of this insect, like all his descriptions, is very accurate, as will be seen by looking at the figure which I send,

BEE-STABBER—*Euthyrhynchus Floridanus*.

which is drawn natural size. "From Georgia. Body purplish blue." This one is greenish blue. "Rostrum pale fulvous; thorax at posterior angles, with a cylindrical emarginate spine; scutellum having three orbicular fulvous spots; feet at base pale fulvous; beneath, under the rostrum, region of the feet, middle of the ventral base, anus, and triangular lateral spot, fulvous. Length one-half inch.

"Female.—Thorax with the anterior and lateral margins and longitudinal line in the middle dull fulvous; the two basal spots of the scutellum sometimes confluent. Length three-fifths of an inch." The one I have from South Carolina, as will be seen by the figure, is a female. Mr. Say received his specimen from Savannah, Ga.

The near relatives of this insect are often predaceous, and so are very valuable. Usually, however, few are so brave as to attack bees, and are wholly our friends, as they destroy many of our most destructive insect-foes. This one, no doubt, also does much good, and it is only to be regretted that he has this one sin to account for. I presume, however, that he will not draw very heavily on the apiary, and so from his general good character we may excuse this one dereliction. Should he so prey upon our bees that we feel the loss, then I could only suggest the same remedy that I have recommended for the "bee-hawks"—the large dragon-flies that attack and destroy our bees—to capture them by hand. I should be very glad if Mr. Ellison could send me a dozen of these handsome bugs. Indeed, I am glad to get insects from bee-keeping subscribers of GLEANINGS and all others, and will gladly de-

scribe, name, and will explain their habits. In sending insects, be sure to put them into a close strong box, so that they may not be crushed in transit. It is not necessary to give them any ventilation, nor usually to furnish any food. Caterpillars should have some of their food in the box with them.

A. J. COOK.

Agricultural College, Mich.

BEST HONEY FOR WINTERING.

O. O. POPPLETON GIVES US HIS VIEWS ON THE MATTER.

REPEATEDLY, during the past ten years or more, have correspondents to our bee-periodicals stated that they "reserve frames of sealed clover honey, to be returned to the bees for winter stores." Others have seemed to prefer basswood honey, while others have been fully as positive that fall stores were as good if not safer winter food. Only a few weeks ago, replies to a query in the question department of one of our journals showed a great diversity of opinion among several of our leading apiarists. Now, why all this diversity of opinion, and what are really the facts in the matter? And as this thing of obtaining the best winter food for our bees lies at the very foundation of successful wintering, I will give my views, hoping to draw out the ideas of others until some slight advance on our present knowledge be made. I will confine myself entirely to the question of best honey, not touching the feeding of sugar syrup at all, leaving that to those who have experience in the use of that kind of food.

For reasons not worth while to mention, a large number of bee-keepers will not or can not use sugar, so this subject of best honey can not be dismissed by simply giving the advice, "Use sugar."

During the first ten or twelve years I kept bees in Iowa, the crop of early or white honey was usually quite small, rarely being one-third of the entire crop, while the yield from buckwheat and fall flowers was abundant. For the last five or six years conditions have entirely changed, so that three-fourths or more of my crop have been white, mostly from the clovers, while the yield of dark or fall honey has been very light. With this change of the honey season came a change in the result of wintering, and the cause had to be investigated. I think that nearly all fruit-raisers have noticed the fact that, as a rule, a full crop meant also a crop of good quality, while a light crop meant also an inferior quality of fruit as well as small quantity. This seems to be a rule of very wide application, the conditions necessary to the production of a full crop seeming to be also necessary to the bringing it to its most perfect condition. This rule, which is so prevalent in the fruit kingdom, seems also to govern in the flower world, in all that pertains to the secretion of nectar. So far as I have observed for a number of years past, whenever any one kind of flowers yields honey largely, especially if the yield is long continued, the quality of the honey is almost certain to be good; while if the yield is light, the quality will be correspondingly poor. Wet and dry weather modifies this rule somewhat, but to a much less extent than I used to suppose was the case.

Several years ago, at the time when my harvest of white honey was so light, I noticed over and over

again that, if any colonies died during the winter, it was almost certain to be one which had had quite a quantity of white honey when going into winter quarters; and when I found any combs in the spring containing white honey, even if fully sealed, it was very apt to be more or less fermented, while fermented dark or fall honey was rarely if ever seen. This occurred so often that I finally adopted the rule of management, never to leave any light honey at all in the combs during winter. I stated, at one or more conventions, that I had adopted such a rule, but I didn't understand the reason for doing so as well then as I do now. As I have already said, some five or six years ago, the relative yields of early and late honey radically changed, and with it came a corresponding change in qualities, and the immediate result was a serious loss in wintering—not so disastrous a loss as I suffered before using chaff hives, but yet too serious to be at all funny—some 40 per cent one winter. This set me to studying on what was the cause of such a complete change, and I am now satisfied that the whole story can be told in the words, "A change in the quality of the winter stores."

I noticed, while extracting, that the fall honey was different from what I usually obtained. Had samples of these later crops and of former ones been submitted to experts, I have no doubt that each would have unhesitatingly pronounced one sample as having been taken from unsealed, the other from sealed combs, even when no such difference was the case. The truth is, the samples would have been entirely different when first taken from the flowers; and no amount of curing, either in or out of the hive, could have made them equal.

I have also noticed for a long time past, that the first yield from any particular flower, such as clover, basswood, buckwheat, etc., was almost invariably of poorer quality than the later yield from the same source would be. This is particularly true if the yield continues for some time, say from two to six weeks. It has been not at all uncommon to obtain a better quality of honey, both in body and flavor, from unsealed combs, filled two to four weeks after the commencement of clover harvest, than from sealed combs filled at the commencement of the same harvest. This fact wants keeping in mind when selecting winter stores.

The following is a brief summing-up of the opinions I have arrived at:

That there is no essential difference in the value of the different kinds of honey for winter stores; that the relative value of the different kinds of honey varies in localities and seasons; that the particular source which gives us the best yield of honey each season is usually of the best quality; also, that, where honey is used as a winter food, much better success will be attained when these facts are observed and acted on.

There are, of course, many other considerations to be taken into account in connection with winter food for bees, but I have confined myself closely to the point of what is the best honey for winter stores, and I hope others will give their views and see if we can not come nearer to an agreement on this point, which is so vital a one in connection with successful wintering. O. O. POPPLETON.

Hawks Park, Fla., Aug. 1, 1887.

This is an important as well as an interesting question, and we should be glad to hear from others in regard to the subject.

ANOTHER PLAN FOR A BEE-HOUSE AND WORKSHOP.

SUGGESTIONS FROM J. H. MARTIN.

HAVING in view the enlargement of my buildings, and the addition of a shop, I have drawn up diagrams as below. My buildings now are nearly like the diagram, with the exception of the shop. The extracting-room is provided with a double door, through which a load of honey for extracting can be wheeled up close to the extractor. In this room I have a stove for rendering wax, etc. Near by should be a closet, or what I call a pantry, in which to set kettles, boilers, pans, and such utensils. When extracting I have all of the windows in the extracting-room darkened, except the one near the extractor. This is let down at the top, and a board 6 inches wide, having two holes five inches in diameter, into which are inserted two double cones of wire cloth, with a small aperture at the points, just large enough for a bee to pass out. I have found that bees would cluster upon the point of a single cone, and work through, while the double cone is effective. A curtain of thin cotton cloth hangs down from the cones over the window-sash, allowing all bees to easily crawl up and escape. Our room is kept very free from bees, even when bees are troublesome. Ordinarily we work with the doors wide open.

I now have a drop of 3 feet from the extracting-

MARTIN'S PLAN OF A BEE-HOUSE.

room to the store-room below. This drop should be 5 or 6 ft. down, instead of three, to allow us to place a 300 or 400 lb. tank, to connect with the extractor in the next room. This tank is not so much for curing honey as to allow any particles to rise that may get through our double strainers. A half-barrel is placed upon a balance under a honey-gate of the tank. The barrel is connected with the arm of the honey-gate, which closes the gate automatically when the barrel is nearly full. You thus save time. If you are called to dinner, and forget that the honey is running, it will not run out all over the floor. I now have to roll all of my honey in barrels up out of the store-room. A door is to be cut, and so arranged that a wagon can be backed up to it, and barrels loaded in with no lifting. Our store-room has been full of barrels, and such a door is necessary.

I now store my surplus combs, etc., over
THE WINTERING-CELLAR.

My proposed enlargement will give me a large room over both cellar and store-room, for storing these hives of surplus combs, empty hives, crates, sections, and empty barrels and cans. The door in the end of the building enables me to enter with my cart or a wheelbarrow. Access is also had from the extracting-room up a short stairs. In this large room I will store and crate comb honey. The doors and windows from the shop, extracting-room, and large store-room, all look out upon the apiary, so our bees are in view at all times. When we find it pays to put in 20 or more acres of honey-plants, and keep in one locality 500 swarms of bees, our buildings will need another enlargement, and it will be a very busy place.

This is not perfect, but it is good so far as it goes, and as far as bee-keeping is advanced at the present time. I should like any criticisms you may make. I think you can possibly make suggestions in regard to a planer, saw-tables, etc. The cellar, as shown, will hold 200 hives, put in quite close. Chaff packing is fully as successful with me as cellar wintering.

J. H. MARTIN.

Hartford, N. Y.

In our wood-working department we have tried to arrange every machine so that as the stuff is finished from one it will be handy to the next machine. It is a waste of time to have the machinery so arranged that the stuff will have to be moved from one part of the room to the other before completion. Your wood-working room seems to be well arranged, though where the room is small and the number of machines are few it does not make very much difference.

WHITE AND YELLOW CAPPING OF COMB HONEY.

THE COLOR OF CAPPINGS DUE TO THE KIND OF BEES.

WE have had a remarkable season here. Up to June 25 it looked as though we should have no surplus honey, and not even enough to winter on. Bloom was abundant in orchard, field, and forest, and yet there appeared to be little secretion of nectar up to the 25th. White clover came out early; and yet, with fields whitened by it, no honey came in more than to encourage development of brood. Too much cool wet weather in May, and too much rain in early June, was the cause, doubtless. Since the date named there has been a fine season, and honey of very fine quality from white clover and blue thistle, and chestnut bloom is very abundant also.

I mentioned last year the yellow capping of comb honey, and soon perceived it to be a trait peculiar to some bees. I am now quite sure of it, notwithstanding the opinions adverse of many to that theory. Some strains of Italians cap without an air-chamber, giving a water color to light honey, others a dull, dingy color. I speak now of natural work, not travel-soiled combs. I remember of seeing no reference to it in print, and should like to ask about it. In thirty years' experience with bees I never saw this yellow capping till two years ago. Last winter, I saw a large lot of yellow-capped honey in Washington City, from Pennsylvania.

My conviction, that it is an inbred trait, comes from observing that some bees always do it and others never, no matter what the sources of honey supply. Such is the evidence. For extracted honey it makes no difference. Can it be possible that bees in the same apiary, at the same time, from the same field, would so widely vary the product—one colony all yellow cap and another as white as snow, as a result of a different selection of food? I ask the attention of friend Doolittle to this.

One of the greatest advances made in late years is the invention of the wood-zinc honey-board. Its use simplifies and lightens the manipulation of comb honey, and I find its use most valuable. Whoever invented and presented to the public this honey-board deserves the thanks of the fraternity.

Charlottesville, Va., July 4, 1887. J. W. PORTER.

DR. MASON'S WASHING-FLUID.

HOW IT MAY BE USED FOR REMOVING PROPOLIS FROM THE HANDS; ITS OTHER USES.

FRIEND ROOT:—On page 346 you ask Mrs. Mason to give her "opinion" in regard to the washing-fluid (the recipe for which is on the above page) injuring clothes, or making them wear out faster. She has used the preparation four or five years, and is satisfied that it does not injure the clothes in washing as directed. Suppose our shirts, sheets, etc., do wear out a week or ten days sooner by using the fluid than they would without its use, it saves much time, and "wear and tear" of the nerves and muscles of those who do the washing. If the fluid were worth nothing for washing clothes, it certainly is very valuable for removing propolis from the hands, and I believe that lady bee keepers, professional men, teachers and others, who wish to have clean hands will be thankful for the recipe, if they once try it. I have improved some in the use of the fluid since I gave the description on the above-named page. I fill a pint bottle about a third full of it, and then fill up with water, and have the bottle near the wash-dish; and when I want to remove the propolis from my hands I pour a little in the wash-dish and wash with it. I also have a bottle of honey vinegar by the bottle of fluid; and as soon as the propolis is washed off, pour a little vinegar in one hand and wash with it; then rinse with water.

You say, "Now, are you sure the potash and borax make it any more effective?" Yes, sir; I am, for I have tried both.

Last week I found a new use for it. I have a Given press for making foundation, and have used a strong solution of concentrated lye to prevent sticking. When wanted last week, the lye solution was missing, and I thought perhaps the washing-fluid would do. I tried it as prepared for the hands, and it worked very nicely—better than the lye solution, and it does not injure the brush so much, and the foundation is not slippery to the hands. I like it better when it is about half washing-fluid and half water. I have used it several times this week with perfect satisfaction.

On page 381 of GLEANINGS for May 15, Mr. Dilworth speaks a good word for Basilicon ointment; and although you (and myself also) "don't believe much in medicines," I believe it is one of the best medicines, where such is needed, that I know of, and "should be in every house." Most bee-keepers

have the material for making it; and that such as wish may make it, I give the recipe: Rosin, five ounces; lard, eight ounces; beeswax, two ounces. Melt together, strain through linen (cotton will do), and stir constantly till cool. It is the best thing I know of for a burn. Soda or saleratus is good, but requires more attention.

A TOOL FOR SCRAPING KETTLES.

KETTLE-SCRAPER.

On page 258, April 1, Dr. C. C. Miller speaks of a "10-cent dish-cloth of iron rings" for cleaning pots and kettles. Please let me tell of a household convenience that our folks think a great deal of for that purpose, and they have several of different sizes. The accompanying diagram shows what they are. One of our boys cut them out of scraps of galvanized sheet iron, with a pair of common shears, and punched the holes, by which to hang them up, with a small punch. Mrs. M. says they are the best things she ever had for scraping kettles, pans, etc., and that she would not be without them. Every side and corner has its use.

A. B. MASON.

Auburndale, O.

We have never found any thing better than common starch paste lathered over the rolls to prevent the wax from sticking; but on certain days we do have trouble with the wax sticking some. We will try to give your washing-fluid a test on our comb-mill rolls. —Your kettle-scraper is easily made, and we have no doubt but that it would be found to be a very useful tool in the kitchen. Our wire dish-cloth is intended for the same purpose, but whether it would do its work any better, we can not say.

FREE PUFFS.

GIVING THE PUBLIC AN INSIGHT INTO OUR INDUSTRY.

IN placing our product before the public there is one method by which we can draw attention to the importance of our industry, and the agreeableness of the product, which is somewhat overlooked. We read of marvelous finds of honey, stories of the freaks of bees, etc., in our daily and weekly press, but seldom do we see an article useful to our interests. Short articles in the newspapers, an illustrated page in Harper's, Frank Leslie's, or the Graphic, an able article for the magazines, all of them could be made charming by enough of the marvelous or novel to draw attention. Describe the condition of the industry here, as compared with it abroad; the apiaries of New Zealand, with a description of them, would interest the public much more than a description of a precisely similarly managed apiary in the next town. The workings of the honey-extractor could be explained very well in an attractive description of a California apiary. The heading, "Honey by the Ton," will help to make it readable. I have some honey-labels with a description of the process of extracting printed thereon. A popular doctor in a neighboring town, after reading it, and tasting

the honey, astounded me by asking me if this was a machine of my own invention. I was most happy to inform him that it was not, and that there were many different manufactures of extractors, and that thousands of them were in use in the U. S., whirling out many tons of honey annually. Upon that he bade me adieu, with an incredulous smile, and doubtless upon arriving home told his wife what that crank from — tried to gull him with. The ignorance of 99 hundredths of the people on this subject calls for the action of hundreds of pens all over the country, with a good story, anecdote, or ludicrous situation, to make readable the instruction we have to impart. Then, and not before, will our product melt from our gaze by the thousands of tons.

J. H. LARRABEE.

Larrabee's Pt., Vt.

We agree with you, friend L., that some such means ought to be utilized. The articles designed for the purpose should be interesting and popular, leaving out all technicalities. They should show that tons of honey can be produced honestly.

GETTING BEES INTO SUPERS.

HOW TO PUT SECTIONS IN T SUPERS.

THE T supers you sent are very nice indeed. The fdn. fastener is a very handy little machine, and works just prime. I had a little trouble in getting my bees into the supers; but then I had been using wide frames when I received the supers. I took all the sections (56) out of the frames, and put them in two supers, putting all the filled ones in the top one, and those partly filled, and those with fdn. only, in the bottom, so you see there was considerable inducement for the bees to go right into the supers. I am using eight frames in the brood-chamber. They have been pretty well filled with brood, but as yet I do not know how they work in the outside row of sections, but will take particular notice when I put on a new super.

There has been a good deal said about inserting the last section in the supers. I find no difficulty. The way I do it is this: For convenience I will number the rows of sections from 1 to 7—1 being on the side of the super furthest from me, and 7 on the side next to where I stand. I first place the super on a flat surface, to keep the sections from falling through, in case the T tins slip out of place. I then put in my T tins, then row of sections No. 1, then No. 7, then 2, 3, 4, and 5, putting a separator after each row. Instead of putting in the 6th row I push the 7th back in its place—that is, the space left for the 6th row, leaving the last row to be inserted next to the side of super, giving one smooth side to work against. In putting this last row in I draw the super a little forward, so that I can guide the bottom of the section with my left hand, while I push down gently and evenly with my right. In putting this last row in I commence in the left-hand corner, making the last section come in the right-hand corner. I prefer this, for then I have two smooth, solid sides to slide the section against, so that, by using your left hand on the bottom, and your right on the top, pressing the section close against the side and end, you will find the difficulty very much lessened; at least, such is the case with me. To make the separators go in easy, I round the corners a trifle, and

find a greater improvement than if left perfectly square. I have tried to make this perfectly plain, and hope you will be able to understand it.

THEODORE JENNINGS.

Rye, N. Y., July 23, 1887.

Putting partly filled sections into the supers is one of the best ways of getting the bees to commence work above. This method has been recommended several times before.

THE OTHER SIDE.

DOOLITTLE'S EXPERIENCE WITH ROBBING.

IT is said, writers give the bright side of bee culture more largely than the dark, which I am free to admit; for when in a happy mood we are more fluent talkers than when sad or perplexed. As I have been perplexed and troubled for the past week or more with *would-be* robbers I thought perhaps not a few of the readers of GLEANINGS would be glad to hear about it. If any thing about bee-keeping makes me feel "dubious" it is to have robbers hovering all day long about every hive in the yard that they think there is a possible chance of getting into. About a week ago the little honey that had been coming slowly in stopped short off, so that there was nothing for the bees to do; while with every day the heat has been intense, which is just the time to put all the possible vim into a robber. Add to this the running of a queen-rearing business in which I was often sending out 30 to 40 queens a day, and the reader will take in the situation. The cover could not be gotten off a nucleus before there was a host of marauders ready to pile in, so that, had it not been for the bee-tent, I could not have done any thing at all, except very early in the morning and late at night, both of which times are very unpleasant to work with bees. The bee-tent would hold the robbers at bay while the hive was being opened and closed; but when the bees, kept outside by the tent, would flock in upon the removal of the same, in would go the robbers, when a fight would ensue, which, in some instances, would have resulted in victory for the latter, had I not promptly closed the hives to some of the weaker nuclei. Then I never before saw robbers so determined or cunning before. They would hover all day long at the entrance of a nucleus, five and six at a time, and alight down with fanning wings as a tired bee would do after being from home a long time, and in this way get past the tired guards. Again, when some of the guards would catch a robber, other robbers would catch hold of the robber also, and hold on, pulling back till said bee got away, when they would whirl around as if looking for another robber, and run into the hive. In this way they would worry out the guards of the smaller nuclei, and keep me on the jump all the while. Talk about the pleasure of bee-keeping when a man has to go on a jump from early morning till after dark at night, in the scorching sun most of the time, with the mercury up from 90° to 95° in the shade, then add this robbing perplexity, and you have something—*delightfully unpleasant*.

Well, there is a pleasant part to it after all, and that is what I wanted most to tell the readers about. The bright side again, you see. What was it could make such a time bright and pleasant? Just this: I beat the robbers! Coming off victor

makes days of struggle and hard toil look pleasant. From such a struggle, with victory, a satisfaction comes that can not be had through ease or indolence. In watching I often noticed that, when a robber slipped by the outside guards into a hive, he would often be led out by a bee from the inside of the hive. This set me to thinking, the result of which was the fixing of every nucleus and weak colony as follows: Heretofore I had the entrance to the hive right direct on to the combs. I now, as fast as I opened a nucleus, took the frame having the most honey in it and set it clear to the opposite side of the hive from the entrance, then the frame having the next most next to that, and the one having the most brood in it last, as I usually use three frames to each nucleus, keeping them (the nuclei) in full-sized hives. I now drew up the division-board and closed the hive. This left the entrance on one side or end of the hive, while the nucleus with its three combs was on the other. If a robber slipped by the outside and inside guards he now had to travel over a foot of space, all along which were scattered guards ready to seize him. If he succeeded in getting by them through stratagem he first came to the division-board; and if he got around that, the next thing was a comb of brood better protected with bees than any other part of the hive. The result is, that, although robbers still hover around, yet not one nucleus, since fixed in this way, has allowed a robber to get a load of honey, if there were bees enough in it to protect it at all. Of course, if I tried to open hives right along without the help of the tent, probably some robbing would be done; but with the help of the tent I am now once more boss of the situation in this the worst time of scarcity I ever saw in hot weather.

G. M. DOOLITTLE.

Borodino, N. Y., Aug. 3, 1887.

Friend D., we have had an experience in robbing this season, quite similar to yours, as you will see by the department of Our Own Apiary, last issue. I do not think that we have had a season when bees seemed more persistent and more determined to thieve than they have this. We have been obliged to use a tent exclusively, and one which was particularly bee-tight. In former seasons it made but little difference whether the tent had one or more holes or not; in fact, a few holes in the peak of the tent were quite an advantage; but this year we found that we had to put an entirely new covering over each tent, for we discovered that the robbers this year had learned the trick of going *down* the holes. We don't recollect that we ever had them do this before. By using the greatest care we think we have also come off victorious—at least, we have managed to make the robbers think there is no use trying, and so only a few stray bees will hover around the tent; but we find it necessary, upon opening a hive, to always use a tent. Our tents are so very light, and easily handled, we would just about as soon work with them as without.—Your plan of crowding the nucleus over to one side of the hive, so that the sentinels, or "guards," as you call them, are strewed all the way from the outer entrance to the inner entrance, we feel sure will work.—Beginners will take a little comfort in knowing that even one of our old veter-

ans are sometimes troubled with robbers; but in ordinary seasons, and with ordinary good care, we believe there is no excuse for letting robbing get started to any very great extent. Of course, a disposition at this time of the year, with part of the bees, to pilfer, can not be avoided; but we can prevent this pilfering leading to very bad results, as a general rule.

DRONE-GUARDS AND ALLEY TRAPS.

DOES THE USE OF PERFORATED METAL HINDER THE BEES ENOUGH TO DECREASE THE NUMBER OF POUNDS OF HONEY PER COLONY?

I HAVE a small apiary, 9 colonies, one mile north of town, on the creek—good pasture, basswood included. The pasturage is better than at home here, where I have 51 colonies. My home apiary is made up of what I consider good stock—pure Italians and good hybrids. The 9 colonies north are common stock, or Italians run down to wicked 32d (?) blood. On these 9 I placed the “guards” I purchased of you, to prevent swarms from absconding. On examination to-day I find some colonies with not *one* pound of honey in the brood-chamber, and all will want about 15 lbs. of syrup each, to winter them, while one good large colony of hybrids, in the same kind of hive, and in the same location, owned by a farmer, has the brood-chamber well filled with honey, the same as my home apiary. Here my colonies had “plenty and to spare,” to the extent that I divided (having no swarms) a few days since, and increased my stock considerably, giving *all* new colonies nearly enough honey to winter them, with plenty of brood and bees, and leaving some to spare in all colonies. From some of the latter I get some surplus also.

Now, all this talk centers in the question, Did those “guards” (which were partly clogged with dead drones) interfere with the workers, or was it the “blood” that told? The colony in the same location referred to did not have a guard on. If I were certain it was the “blood” which caused the “break” in this heretofore energetic and well-disciplined army, I would depose the present female incumbent and inaugurate a new dynasty.

Nevada, O., Aug. 5, 1887.

WM. M. YOUNG.

I am rather inclined to believe that both the blood and the guards were responsible for the difference in results. The guards which you purchased, we find, on looking up in our bill-book, were what we call entrance-guards, and are designed not so much to catch queens when they are about to issue with the swarm as to prevent drones from passing the entrance. During the time that drones are flying they should be removed occasionally, and cleaned of drones which may have become lodged in the metal. If you had used the Alley drone and queen trap combined there would be no trouble from drones clogging the metal. But even these must be removed occasionally to dump out the drones that may be “upstairs.” From our experience this season I am not sure but even the Alley trap (if kept at the entrance during the whole season) might so hinder the bees as to affect appreciably the honey crop.

HEADS OF GRAIN FROM DIFFERENT FIELDS.

DO BEES EVER TRY TO DECEIVE EACH OTHER?

I HAVE been feeding up a weak colony, and robbers were attracted by the food. Some of them forced their way into the hive. I contracted the entrance to three-fourths of an inch, and then they defended themselves. After half an hour or so I noticed what I believed to be a number of robbers coming with just a little pollen on their legs, by which they expected, as I suppose, to gain admittance into the hive. Some with pollen on their legs were readily admitted, while others with just a little pollen would act just like robbers, by flying all around about the entrance, and dodging whenever called upon by the sentinels for the pass-word. Were these latter bees robbers?

Corn is in full tassel and pollen is plentiful, but honey is scarce. White clover, which is our main honey crop, gave us but little honey this summer, owing to the long severe drought in May and June. June 22d I sowed the bushel of buckwheat that I got of you, and on the 19th of July it began to bloom—just 27 days after sowing. The alsike clover seed I got of you was sown April 1st, and perished in the drought. I shall sow earlier next year. I have a thought of raising buckwheat in the future, instead of common wheat. It will give me pasture for my bees, and make more money as grain than wheat. We get from 10 to 20 bushels of wheat per acre, and get 60 cts. per bushel for it. Now, if buckwheat will yield 10 bushels per acre, and sell for \$1.00 per bushel, it will pay as well, or better, than wheat. Then, too, it is such a trouble to get our wheat thrashed out. They don't like to come to thrash unless you have 200 bushels or more—at least, they charged me \$15.00 to come and set a machine in my field. I want to get some instructions as to the cultivation and harvesting of buckwheat. No one here knows anything about it.

J. G. NANCE.

Bellevue, Ky., July 23, 1887.

Friend N., I have spent a good deal of time in trying to determine just the point you make; that is, whether bees have enough brains to attempt to obtain honey (not money) by false pretenses. Although appearances, as you have shown, would seem to suggest at first that they do, I think it is a mistake. The bees that had a little pollen on their legs did not place it there in order to make believe they were honest: they belonged to a class that had, by daily robbing, got uneasy and discontented. They were not ready for honest labor; but finally finding nothing to steal they put out for the fields for the purpose of gathering pollen, like the rest. The day, however, was hot, and the labor fatiguing—especially to bees that had had a taste of the excitement of robbing, and so they came back home with half a load, and flew about the apiary to see if there were not a chance for some excitement. Now, under such circumstances they would be seen trying hard to rob with little bits of pollen on their legs. Other robbers which you saw catching hold of robbers, seemingly just to make believe they were sentinels, were likewise of this class of demoralized old fellows. They were hanging around, as we sometimes see

human beings, with their hands in their pockets, sitting on hitching-posts; and as Satan always finds some mischief for idle hands to do, they were ready to pick and pull at anybody who came along. If any trouble is started, these people grab hold and make a pretense of being eager to restore law and order, trying to pass themselves off, as it were, for good honest citizens working hard for law and order, while the truth is, they are sneak thieves waiting for a chance to steal, where there is no danger of getting into trouble.

In regard to buckwheat versus wheat, if your land is suitable you ought to get thirty or forty bushels an acre, instead of ten. The crop, however, is quite uncertain, and it is a hard matter to lay down rules for the cultivation of buckwheat in all localities. The price paid for it is also quite uncertain. It is not nearly as regular as wheat. I should be very glad indeed to have a little treatise entirely on the cultivation of buckwheat. At the present time we have a crop of nice buckwheat in full bloom, and yet the bees scarcely notice it. In an adjoining county I saw a field of nice buckwheat in full bloom a few days ago. The proprietor had sown this expressly for his bees, but he said the bees didn't work on it at all. It may be because it is too early in the season.

TROUBLE IN TRANSFERRING.

I transferred a colony of bees into a Simplicity hive last evening. It was very weak, but had some honey and some brood. In about one hour after I had transferred them, the bees had nearly all left the hive. The queen was, or seemed to be, very much excited. She ran all over the combs. Now, will you please tell me what was the cause of those bees leaving the hive? Did I make a mistake in transferring them, or did they get discouraged because they were so weak? My wife and I transferred four colonies before, and had the best of success. She can beat me working with bees. She never wears a veil in transferring, while I have to wear one. N. F. CRIPE.

Montevallo, Mo., July 20, 1887.

Once in a great while, friend C., a colony will seem to be displeased with their new arrangements after being transferred, and under such circumstances the bees and queen will desert. It has been my impression, however, that the work was not very skillfully done when such things happen as you mention. I may, however, be mistaken. In your case the queen seemed to be alarmed and frightened, and she perhaps communicated her demoralized state to the whole colony. I have been a great many times puzzled to know where the bees and queen went to, but concluded they had gone into other colonies, but I have always been unable to find where.

THE MOSQUITO-HAWK, AND HOW THE BRAZILIANS CATCH IT.

I paid a visit the other day to a Portuguese gentleman who lives at Carlos Pass, in this county, and he told me how the apiarists of Brazil rid themselves of this terrible enemy of the bees, the mosquito-hawk, or dragon-fly. The method employed is to stick stakes in the ground throughout the

whole apiary, the sides near the top of the stakes being pierced thickly with holes about the size of a leadpencil. These holes are to receive small pins, about four inches long. These pins are covered thinly with a sticky substance called in Portuguese "gomo di igo." Now, when the bee-hawk seizes a bee he alights on the first twig near him, to eat his victim; and as these little wooden pins are a very inviting place for him to alight, he is almost sure to alight on one of them, and, twining his legs around the pin, is caught and held fast by the gomo, and is killed by the apiarist, and another coat of gum is put on the stick, and it is ready for another hawk.

Now, as almost all the damage done by these hawks is done an hour before dark, the apiarist can be on hand and kill nearly all that visit his yard; and as the hawk, on being caught, liberates the bee he has caught, I believe this plan is worthy of a fair trial. Will you please tell me if gomo di igo is bird-lime, and where can I get it? May be Prof. Cook can tell us how to make it. For stakes, the Brazilians use canebrakes or reeds, called "canista," or "pitto." The Cubans call it "caña brava."

W. W. WILSON.

Punta Rassa, Florida, July 25, 1887.

Friend W., I should think the substance is bird-lime, or something quite like it. Some years ago we discussed the matter of bird-lime pretty fully, and several recipes were given for making it. The idea seems to be quite sensible as well as ingenious; and where mosquito-hawks are a pest I have no doubt it would fix them.

THE WORKING OF THE MITCHELL HIVE; A PATENT MOTH-TRAP, AND HOW A FARMER WAS SWINDLED BY IT.

I am in a section of country where Mr. Mitchell has been selling quite a number of hives. Among the many small apiaries that I have visited I found but one L-frame hive. Mostly the American and the Mitchell hive are used. One man said when he first saw a Mitchell hive he thought it looked nice, and every thing looked as though it would just be fun to take honey from such a hive. But when he undertook to take honey he remembered about bees using propolis in every crack, and said it was a wonderful job to take honey out, as every thing was glued tight. A Mr. Kieffer, not far from me, said a man came around to him one day with a patent wire-bottom bee-box to prevent moth and robbers from getting in. Mr. Kieffer agreed to pay him \$20.00 for the township right. After the patent-right man made out the right, or paper, to that effect, Mr. Kieffer handed him his \$20.00. Each man went his way. After Mr. K. had gone home, he thought that night he would read over his township right, and was very much surprised to find he had paid the money for a farm-right instead of a township-right. The swindler, of course, had left on the first train, for some other place.

D. E. BAUGHEY.

Waynesboro, Pa., July 11, 1887.

Friend B., your neighbor was swindled without question; but even had he received what he paid for, I do not see that it would make any great difference, for I don't believe I know of a farm-right, township-right, or State-right to a patent hive that I should consider worth a copper. That old-fashioned way of doing business seems to be passing out of date and out of memory.

THE DROUGHT IN ILLINOIS.

I think there has been less rain the last 11½ months than since I have been in the State, in the same time—22 years; but 8 months before that was very wet, both fall and spring. Bees were in good order the first part of April, but they had to draw on what winter stores they had left in May.

DO BEES EVER STARVE IN JUNE?

One year ago they were booming, now the reverse. Some worked a little in sections, others not. There is plenty of white clover, but it turned brown so quick it had time to secrete but little nectar, as it was very dry and hot. Some days it was above 100° in the shade; and in the sun, against a building, it ran up to the top—130°. Little apples fall off and soon bake brown; so did blue grass. Hay is about ¼ the crop of last year. Small grain is also short, and the next two months will decide on our staple here—King Corn. I still hope the bees will get enough this fall for winter.

Limerick, Ill., June 28, 1887.

E. PICKUP.

Bees do sometimes starve, even in June. Reports recently seem to indicate that some will starve this year unless fed.

CARNIOLANS, AND THEIR DISPOSITION TO SWARM.

I am a novice in bee keeping, yet I have had what seems to me a strange experience, if the books I have read are to be relied on. I have a colony of Carniolan bees, in a chaff hive, which cast its first swarm on the 15th inst. It swarmed again on the 26th, and a third time on the 28th. The last being small, it was bived with the second swarm. In hiving them it was discovered that there was more than one queen with the last swarm. We examined the swarming-box, and took from it four large fine-looking queens. We afterward thought it best to examine the condition of the parent hive. We found it in fine condition, except that it had been very much reduced by swarming. We found, also, four other queens with as many as ten queen-cells yet to come out, still in the hive. We removed the queen-cells and two of the queens, and left two still in the hive. The hive contains about 75 lbs. of honey, but very little brood, and no fresh-laid eggs. Just how it will work out, I can not, with my limited experience, estimate.

J. C. BOUDE.

Lexington, Va., June 29, 1887.

One of the characteristics of the Carniolans is their great propensity to swarm. In this view of the case I do not know that what you relate would be any thing strange. Even Italians will sometimes behave themselves very much as did your Carniolan swarm. Sometimes as many as 20 young queens are found in a single second swarm. Not long ago, one of our correspondents said positively there were over 100 in one of his second swarms. See "Queen-Rearing" and "Swarming," in the A B C of Bee Culture, for further particulars.

BEES AND FRUIT; HONEY OF BLuish TINT.

I agree with Mr. Doolittle as regards bees eating fruit. I have several large fig-trees. Sometimes the trees are covered with bees until it looks dangerous to go near them; yet I have never seen a bee eating a fig that was not very ripe and bursted open. It has rained every day for three weeks. Bees, of course, are gathering no honey, consequently they are eating fruit. What do they do with the fruit when they eat it? Do they store it in

the cells? I took some comb honey about a month ago that was so blue I did not know what it was gathered from, unless it was from the elder. It was in bloom, and the bees at work on it, when the honey was gathered. The comb was very white. I see that you refer to such honey in a former issue, page 512.

J. C. SMYTHE.

Caseville, Miss., July 9, 1887.

I am inclined to think that the honey you mention was from the juice of raspberries. When there has been a dearth of honey during the time raspberries were ripe, I have dissected bees which came in heavily laden. The liquid which came from the honey-sacks of these bees was of a bluish tint. The taste was strikingly like the raspberry. While the honey above may not have been entirely from this source, yet it probably had enough of raspberry juice to color it.

HOW TO MAKE T TINS WITH A TINNER'S COMMON FOLDER.

I have made T tins on an ordinary tin-folder. My plan is as follows: I took strips of common roofing tin, and bent them first like this,  exactly in the middle. I then set the machine and bent one edge thus:  I next set the machine the same as at first, and finished the first bend, so that the tin looked like this,  which was as far as the folder would bend it. I then laid it on top of the machine, so that the last bend was close to the joint, and the other bend underneath. I next moved the folder around and on to the tin, and pressed the fold together thus:  I took one screw out at each end of the folding-plate (these screws hinge  this plate to the machine), pushed it away, put in the tin, pulled the folding-plate back, and held it there while I bent the other edge, and the tin was done. The machine I used was a common tinner's folder. The above may be of use to some who do not care to send a distance for a few T tins.

W. E. PETERMAN.

Trappe, Mont. Co., Pa., July 26, 1887.

Friend P., you have shown that a tinner's folder *can* be made to fold T tins. While it is possible to make them in an ordinary folder, yet it is impracticable to make very many. We gave your letter to the foreman of our tinning department. He succeeded in making a very nice T tin, but he says he does not think he could make over 100 a day by that plan, whereas he can make with our T-folder as many as 2500. Another thing, he says that your plan strains the folder, and might therefore injure it.

KING-BIRDS DESTROYERS OF YOUNG QUEENS.

In GLEANINGS for July 1st the question is asked, "Do king-birds swallow their victims?" If they are very hungry, I think perhaps they may do so, and that chickens, under like conditions, may do the same thing; but give king-birds plenty of queens and moth millers to eat, and chickens plenty of corn and wheat, and my opinion is that you will find very few worker bees in either king-birds or chickens. For the last seven or eight years I have kept from 150 to 250 stands of bees here on the banks of Feather River, where king-birds are plentiful. I have shot a great many of them, and have always failed to find any part of the bee in their

crops; and taking into consideration the fact that they come around when the drones are out, and almost always go away when they go in, I conclude that their mission is the destruction of queens only. In fact, I have seen them dart down where drones were flying thickly, catch something and make off with it, and about a dozen or more bees follow it as far as the eye could reach. Now, I think if there were no king-birds few queens would be lost.

T. G. H. JONES.

Nicolaus, Sutter Co., Cal., July 13, 1887.

ARE THE STRIPS OF ZINC IN THE SLATTED HONEY-BOARDS A HINDRANCE TO THE BEES?

I have been using, this summer, your slatted wood-zinc honey-board, the Heddon slatted honey-board, and the Hutchinson queen-excluding honey-board, ten of each kind. I think the wood boards of either kind are of very little if any hindrance to the bees going into the sections to work, but I have not been able to get a single colony to work well through the zinc. In one of Dr. C. C. Miller's letters he spoke of one of his friends who was able to keep the queen from laying in the boxes, without the use of a queen-excluding honey-board. Dr. M. also said he could prevent the queen from going into the boxes. His friend said it was one of the secrets of the trade. Now, if he or the doctor would divulge that secret I think he would do many bee-keepers a kindness.

KING-BIRDS.

I have found bees in the crops of king-birds. They are often in my yard, catching bees by sunrise, and late in the evening, when no drones are flying. The English sparrows catch many bees for me. I often see the large dragon-flies near my yard, catching the bees, and they do it very nicely too.

White clover was a failure here. Basswood did very little. Sumac has turned out honey well, and is yielding some yet.

E. D. HOWELL.

New Hampton, N. Y., July, 1887.

In our experience this season with the slatted honey-board, and the same with strips of perforated zinc slid in between the slats, we could see no decided difference in favor of either. However, it seems to me that under certain circumstances the bees would more readily enter sections where the strips were not used between the slats. If we are correct, Dr. Miller uses no perforated metal in his honey-boards, and we think, also, he has no trouble from the queen going into the supers and laying. I am sure there is no secret about it; but whatever it is, Dr. Miller will, on seeing this, give us further light. There is this to be said, however, in favor of the slatted wood-zinc honey-board: When contraction is carried to such an extent that the brood-nest is reduced to one-third of its former capacity, the queen, on finding her field of labors limited below, will pass above into the sections. To prevent this the strips of perforated zinc have been added to the plain slatted honey-board.

PERSISTENT SWARMING, AND THE CAUSE.

I am going to write to you to see if you or any of the readers of GLEANINGS can tell me the cause of our bees acting so funny. We started out this spring with five hives, and we have had but one swarm from them. It was a small swarm. We put

them in a Simplicity hive. They all went in, and were quiet the rest of the day; but the next morning, before we had eaten breakfast, they came out again and we put them in another hive, but they would not stay. They came out about every half-hour that day, and we put them back every time. We went out the next morning to see what had become of them. They were still in the hive, and are there yet, but are not doing anything. That was on the 20th.

C. C. BRUCE.

Helena, Ark., June 21, 1887.

Friend B., the old stereotyped remedy for troubles of this sort is a frame of comb containing unscaled brood. Of course, there are exceptions occasionally to this rule; but they are so few I should call it almost invincible.

BAD NEWS FROM J. B. MASON & SONS; DOING BUSINESS WITHOUT HAVING PROPERTY INSURED.

I sent myself to write you with a heavy heart. Saturday morning, at half past two o'clock, fire was discovered in our shop and store. The alarm was given, and every thing done that could be done with what facilities there were at hand, but it could not be saved—nothing was saved—3000 dollars' worth of goods burned up in a very short time. After years of struggling along to build up a business it seems very hard. You know, friend Root, something how to sympathize with us. I don't know that you do wholly, for it has taken every thing we had but our bees; and we want to say through GLEANINGS that we shall be unable to fill any more orders for this season, at any rate, except for bees and queens.

J. B. MASON & SONS.

Mechanic Falls, Me., Aug. 1, 1887.

I am sure the readers of GLEANINGS all extend their sympathy to friend Mason in his trouble; but I scanned the letter through anxiously to see whether or not he was insured; and I wish to say once more, that dealers, in bee-keepers' supplies especially, should make it a point to carry some insurance just as soon as they begin to do any business of any account. If the insurance cover even a part of the stock, it furnishes ready money to start up in business again; but where there is no insurance whatever, the result is many times almost ruinous. If you can not afford to pay the trifling amount needed to insure the property, don't go into that kind of business. I once knew of a wholesale house doing a large business, that refused to give credit to a man of moderate means unless he would constantly carry insurance. Insurance helps a man to pay his honest debts, and thus keep his name good, where, without insurance, it might be entirely out of his power. I do not mean by the above that you should carry the matter of insurance to extremes, but carry a moderate insurance, patronizing some one you know—your neighbors or fellow-townsmen; and have an arrangement made so it can not run out and be neglected. We trust to hear that friend Mason had at least some insurance on his factory. When our warehouse was burned, the insurance covered only a little more than half the amount lost; but this money in ready cash enabled us to replace promptly and without delay every thing lost that was necessary to go ahead with business.

A "RECIPE" TO PREVENT STINGING.

Please give a recipe for stopping bees from stinging every one who goes out of the house. I divided four colonies, and ever since they want full possession of the yard.

A. S. VANSYOC.

Indianola, Ia., June 28, 1887.

If you want to make bees very cross — so cross, indeed, that it is hardly safe to venture into the apiary, just let them get to robbing. In transferring, let the bees help themselves liberally to the sweets; let them get into the honey-house, and get to going there on your new honey. Friend V., the only way we know of to prevent bees from being cross is just the converse of the above. Be very careful not to let the bees get started. Don't let even one bee get a sip of honey that does not rightly belong to him. If you have pure Italians, and robbing is a thing unknown in your apiary, almost any one can go into it with impunity. Even cross hybrids, if you are careful, and do not let robbing get started, will be kind o' decent.

STRENGTHENING A NUCLEUS; QUESTIONS BY A BEGINNER.

To help a weak swarm, will it be safe to take combs, bees and all, out of a strong one and put the same into the hive with the weak one? Will the bees fight, or will there not be danger of having the queen killed? Would it work, in case the weak one had no queen?

J. B. BAUMBERGER.

Washington, Kan., June 27, 1887.

The best way to strengthen a weak colony having a queen is to give them one or two frames of hatching brood. In a few days there will be a large force of young bees. If you desire to further strengthen the colony, give them another frame or two of hatching brood. In colder weather be careful not to give them more frames than the bees can cover easily. You can take frames of brood with adhering bees from a strong colony, and put them into the weaker one; but if the latter has a queen there is danger that the bees from the stronger colony will kill the queen, though they probably would not, because all the old bees would return to their old stand, leaving the young ones on the combs. These, of course, would not be likely to molest their new mother. If the weak colony has no queen you can do almost any thing with them in the way of uniting that you wish, with no trouble. See "Nuclei," in the A B C book.

A CHEAPLY EXTEMPORIZED SOLAR WAX-EXTRACTOR.

I have a good sun wax-extractor which I made as follows: I first took off a large pressed-tin pan. Into this I fitted, about half way from the bottom, half a barrel-hoop, with wire cloth tacked on, placed inside of the pan to receive the comb and wax refuse. The whole was then covered with a sheet of glass, and it was done. It certainly is a grand affair to keep all small pieces in, as well as any cappings, as the sun reduces the wax very quickly.

A. L. KLAR.

Pana, Christian Co., Ill., July 8, 1887.

Your wax-extractor is complete, except that it has no reflector other than the flaring sides of the pan. In hot weather it might do very well without a reflector; but

we find that ours works a great deal better and faster when the reflector is up than when it is not.

BEE REPORT.

I began the season with 30 colonies. By taking two frames and brood from each of the several hives, placing in their stead frames of fdn., I have made five additional colonies. Into two of the new-made hives I carried, with the brood-frames, a queen, and allowed the hives from which the queens were removed, to create a queen. The other three new-made colonies had to make their own queens. All now have laying queens. I had only one natural swarm. If others came they absconded, unknown to me. About one-third in number of the hives were stored in sections from 10 to 30 lbs. each. In other apiaries I have not heard of any natural swarming, and all say that honey-storing is very limited.

I see our bees work on the sunflower and mustard bloom very vigorously. I have sown half an acre to buckwheat. I suppose that amount is hardly a circumstance for so many bees as we have. Every little will help, but I should think that, for 30 or more colonies, less than five acres sown to any blooming plant would be poor dependence.

JOHN CADWALLADER.

North Indianapolis, Ind., July 17, 1887.

BEST PACKING FOR WINTER.

I wish Ernest to tell us what he is satisfied is the best material to make or fill the cushions with to lay over the bees in winter. I do not like chaff, as it gets musty; and then when laid aside in summer, mice are sure to tear the whole to pieces. I should like soft dry planer chips if I could get them. Now, I can't see why the common dry sawdust (not the long stringy kind) would not be as good a thing as could be had. When we want to pack our ice we ask for nothing but sawdust to keep out the heat; and why not to keep out the cold from the bees? What do you say? I use the Hill device in principle, so the cushion can not rest heavily on the frames, and it leaves a space for the bees.

Moscow, Vt., July 11, 1887.

J. W. SMITH.

For winter packing over and around the brood-nest, we prefer wheat chaff. It is cheap, light, and always obtainable—at least, in most localities. The sawdust which you speak of might answer just as well. Our principal objection to it is, that it makes the cushions too heavy to handle. As to mice gnawing into chaff cushions, we scarcely ever have any trouble from that source. During summer we always store our cushions in a mouse-proof room.

THE QUEEN AS RULER.

Mr. R. B. Robbins' experience with a swarm, July 15th issue, together with the foot-notes of the editor, corroborates very closely my experience this last spring. I was looking at my bees, and upon opening one hive I noticed the queen near the top of the frame, running and twisting herself in wild excitement, and all at once I heard a sharp "peep, peep, peep." This lasted nearly a quarter of a minute, when suddenly every bee in the hive was uttering the same shrill note, and they rushed for the entrance. Not familiar with such proceedings I at once called for my smoker, but soon saw that it was only a natural swarm, and so I did not need smoke. I kept the enameled cloth off, through the whole

proceedings; and when they settled I lifted out all the frames to look for cells. I noticed two cells nearly half built. It was, no doubt, a natural swarm, and the bees all appeared perfectly quiet in the hive until the queen began her peeping, for I did not use any smoke to excite them.

B. G. LUTTRELL.

Luttrell, DeKalb Co., Ala., July 20, 1887.

REPORTS DISCOURAGING.

THE DRY SEASON.

THE honey season here has not been a successful one, speaking generally. We have had one of the most trying seasons for years, there being no rain of any consequence since the latter part of May. The fruit-bloom was a total failure, and bees were very late in breeding up; and the extreme dry weather having cut off the supply of nectar from white clover and basswood, it has been about all bees could do to gather enough to live on through the season, and be well supplied for the coming winter. Many farmers are now feeding their stock hay twice a day, and all stock eat it with as much relish as they would in December. Buckwheat has not come up at all, and corn will not be half a crop. It seems as though our lines were cast in hard places; but we never say "die," but look for a better show next year, Providence permitting.

M. W. SHEPHERD.

Rochester, O., Aug. 6, 1887.

No honey yet—rain, rain. Mrs. C. S. DAVIS.
Bethel, Vt., July 12, 1887.

BEES FAILED—102° IN THE SHADE.

Bees have failed in this section of country, and in Eastern Illinois the weather is very dry. The temperature was 102° in the shade for several days.

Sylvania, Ind., July 26, 1887. C. V. LINDLEY.

The season is very poor here—not more than one-fourth of a crop. My bees are, however, in good condition. I have my 182 colonies (spring count) in three apiaries, and have had fifteen swarms in all.

Edinburg, O., July 15, 1887. CHAS. R. BINGHAM.

LACK 2000 LBS. OF HONEY FROM LAST YEAR'S CROP.

My 58 colonies of bees will lack 2000 lbs. of making as much honey as they did last year. This is the worst season for honey I have ever struck since I have been keeping bees.

J. K. NICHOLS.

Danville, Ind., July 25, 1887.

"WHAT HAS THE HARVEST BEEN?"

The above heading in July 15th No., 1887, pages 532 and 533, will answer for many around me. W. Z. H. has told it as it is and will be before spring comes again.

I. R. GREEN.

Unadilla, N. Y., July 26, 1887.

POOREST EVER KNOWN.

The honey season has closed out, and has been the poorest I ever knew. No honey has been made from white clover. The basswood season was very short. Bees have had nothing to do but rob one another.

A. A. IRISH.

Big Spring, Mich., July 19, 1887.

NO RAIN YET.

Bees are not doing any thing this summer. In the spring it was too wet, and now it is too dry. If we do not get rain soon it will be a question in my

mind whether they will make honey enough to winter on.

G. H. HOLMES.

Defiance, O., Aug. 1, 1887.

HAD TO FEED, FOR THE FIRST TIME IN MANY YEARS.

Bees have not done any thing. They opened up strong, and used up all their stores before white clover, so we had to feed—the first time for many years. White clover did not yield any honey. We have had no swarms. I don't suppose there are 50 lbs. of honey in the brood-nests of my 60 hives. We have had plenty of rain lately, so we have good hopes for the fall yield, which, with me, has always been the best.

GUSTAVE GROSS.

Greenville, Ill., July 23, 1887.

REPORTS ENCOURAGING.

FILLED THE HIVE FULL IN EIGHT DAYS.

WE have 21 colonies in good shape. They are working for comb honey. I hived a swarm June 10th, and June 28th they had filled the hive and a 21-lb. section case full of honey, from linden. They are now working on a second case I placed under the first.

GEO. W. BALDWIN.

Forest City, Mo., July 13, 1887.

Bees are doing grand.

GEO. S. WASON.

Hawkesburg, Ont., July 25, 1887.

Basswood boomed for 7 days, the best I ever knew. It came out July 1.

D. HOXIE.

Wautoma, Wis., July 9, 1887.

THREE TONS OF HONEY.

Bees are doing finely. I commenced the season with 26, and increased to 60. I shall get about 3 tons of honey this season, one-third comb.

Honey Grove, Tex., July 28, 1887. G. F. TYLER.

BASSWOOD GOOD.

White clover was a failure with us. Basswood was good. My bees are gathering honey from sweet clover. No other honey-bearing plants are in bloom, and won't be till August. If it continues dry much longer, fall honey will be scarce.

Hillsdale, Ia., July 13, 1887.

E. W. FITZER.

SWARMING WELL.

The increase of swarms is favorable—about double in average apiaries. The honey-yield was light—I think not more than half an average. In my apiary I had 19 swarms the first of May, and in June increased to 38. Up to the middle of July I got 500 lbs. of comb and 100 of extracted. The average of this locality is about 20 lbs. per hive. At this date the bees are working well.

Ionia, Mich., July 28, 1887.

H. SMITH.

HONEY ADVANCED IN PRICE.

The honey crop in this State, as a general thing, has been a failure, as near as I can learn. Too much wet weather, I think, has been one of the reasons, although we had a good clover and basswood bloom, consequently honey has advanced. I am now selling comb honey in 1 and 2 lb. sections at 5 cts. per pound more than last year. Some of the farmers who keep a few swarms of bees have lately sold their honey at 10 and 12 cts., and are now sorry they rushed off what little they had.

E. L. WESTCOTT.

Fair Haven, Vt., July 21, 1887.

NOTES AND QUERIES.

WHAT IS THE MATTER OF THE BEES?

I HAVE three colonies, the bees of which crawl out of the hive and die; some of them turn on their backs and die in that position. Those that die appear to be puffed, and look to be nearly one-half larger than their natural size. I have never had any thing like it. The brood appears in good condition. I can't see any pin-holes, but a few dead grubs, which I thought was caused by not having bees enough to take care of the brood. The queens are vigorous, and look all right, and there is no unusual smell in the hive.

Massillon, O., May 19, 1887.

H. BEATTY.

[Friend B., we can not tell you what the trouble is, unless it is dysentery or spring dwindling. See the A B C book for a full description and discussion of the matter.]

HONEY CANDYING AS SOON AS GATHERED.

Our honey down here candied as soon as gathered, so that we can not extract any. What is the cause? Will bees use it in rearing brood? It is so hard that you can cut it with a knife.

Pleasant Hill, S. C., July 4. G. W. BECKHAM.

[It is rather unusual to have honey candy so soon. You do not state the probable source of the honey in question. The bees will probably use it this time of year, without any trouble.]

BLACK BEES ON RED CLOVER.

There is a clover-field one mile from my place. My neighbor sowed red clover for his black bees — "make honey out of it," he said. I see mine flying in that direction. I suppose they gather honey from there.

A. HENNO.

Aurora, Ark., July 15, 1887.

THE SEASON FOR MRS. HARRISON.

Not one of our colonies has died from starvation up to date, August 6th, although we have not fed any, excepting three swarms, which are all we have had this season. The price of honey is on the rise, notwithstanding that convention to boost the price failed to materialize.

MRS. L. HARRISON.

Peoria, Ill.

COOK'S HOUSE FOR THE APIARY.

Perhaps criticisms by the "smaller fry" are not in order, but I'll make the venture. If cars running past an apiary will disturb the bees in winter, would not the use of an engine and machinery in the shop of Prof. Cook also produce a detrimental effect upon the bees?

WILLIAM E. GOULD.

Fremont, Mich., July 20, 1887.

SEVERE STINGING.

We had a case of severe stinging ten days ago. Mr. M. went up in a tree 30 or 40 feet after a swarm, sawed the limb off, which fell so as to dislodge the bees, when they returned and alighted on his head, smothering him and stinging at the same time, which almost cost him his life, friends and physicians watching for 1½ hours, expecting him to die. He is up now, though whether feeling entirely well or not I can not say.

M. L. BREWER.

Philo, Ill., June 23, 1887.

EXTRACTED 6 LBS.

The season with us is a rather discouraging one. Clover was a failure, and basswood not much better, but there seems to be considerable honey gathered from red clover at this date, and we hope to get enough to winter, without feeding. I have

already extracted six pounds, and I hope to get a few more. We will, however, not complain, but "get the dish right side up" for next season, and drive at something else, meanwhile, to "make both ends meet."

CHRISTIAN WECKESSER.

Marshallville, O., Aug. 8, 1887.

IS IT NECESSARY TO USE ACID IN SYRUPS, FOR WINTER FEED?

Can vinegar, or any thing else, be used as a substitute for tartaric acid in making sugar syrup, on which to winter bees? If so, please give me the proportion to use.

JOHN MAJOR.

Cokeville, Pa., July 10, 1887.

[Yes, you can use vinegar as a substitute for tartaric acid in sugar syrup; but our experience for a good many years, without the admixture of either acids in the syrup, has shown that they are not needed. It is thought by some that the acid will prevent granulation, but we never have any trouble with the syrup granulating, made with sugar and water only.]

MUTH'S PLAN OF CURING FOUL BROOD A SUCCESS.

I have had a big fight with foul brood. I lost nearly all about three years ago, but I am all right now. I destroyed neither bees nor hives. I followed Mr. Muth's plan. I drove the bees into clean combs and used an atomizer with medicine as he directs, two or three times for two weeks. I see one man advertises, "Foul brood, no! Never saw a case." For my part, I should have more confidence in him if he had had such experience. His apiary may be rotten before he knows it.

M. G. YOUNG.

Highland, N. Y., June 27, 1887.

DO KING-BIRDS SWALLOW WORKER-BEES?

On page 514 you ask, "Do king-birds swallow worker-bees?" In May, 1884, I killed about 20 king-birds in my apiary, and opened a dozen of them. I found worker-bees in every one of them. I believe it was before any drones had hatched. Tell those bee-keepers who found nothing in the crop, to look in the gizzard. I very much doubt if a king-bird has any crop. I think their food passes from the mouth directly to the gizzard. When drones or queens are flying they take them in preference to workers.

Mauston, Wis., July 11, 1887.

F. WILCOX.

[Many thanks, friend W. In addition to your letter we have had two or three others, saying that king-birds do swallow worker-bees. One instance showing that such is the case is worth more than any number of others trying to prove that these birds do not swallow bees.]

THE GUILTY KING-BIRD, AGAIN.

I shot a king-bird last week in my yard, opened its crop, and found seven of my bees in it. We call them bee-martins. They have a little crown of bright-yellow feathers on top of the head, which resembles a flower.

R. B. WILLIAMS.

Winchester, Tenn., July 23, 1887.

THE EATING OF COMB HONEY, AND ITS EFFECT ON THE SYSTEM.

I should like to hear from you in regard to the effects of eating comb honey. I am quite healthy, and regular in my habits, but I find, when I eat liberally of it, that I become quite constipated. I attribute it to the wax, but I may be mistaken. Is it thoroughly soluble in the stomach?

P. J. CHRISTIAN.

New Orleans, La., July 17, 1887.

[I can hardly think that wax has any thing to do in the matter. There are very few who can eat either extracted or comb honey in a large quantity at a time without some bad effects.]

Every boy or girl, under 15 years of age, who writes a letter for this department, CONTAINING SOME VALUABLE FACT, NOT GENERALLY KNOWN, ON BEES OR OTHER MATTERS, will receive one of David Cook's excellent five-cent Sunday-school books. Many of these books contain the same matter that you find in Sunday-school books costing from \$1.00 to \$1.50. If you have had one or more books, give us the names that we may not send the same twice. We have now in stock six different books, as follows; viz.: Sheer Off, Silver Keys, The Giant-Killer; or, The Roby Family, Rescued from Egypt, Pilgrim's Progress, and Ten Nights in a Bar-Room. We have also Our Homes, Part I., and Our Homes, Part II. Besides the above books, you may have a photograph of our old house apiary, and a photograph of our own apiary, both taken a great many years ago. In the former is a picture of Novee, Blue Eyes, and Caddy, and a glimpse of Ernest. We have also some pretty little colored pictures of birds, fruits, flowers, etc., suitable for framing. You can have your choice of any one of the above pictures or books for every letter that gives us some valuable piece of information.

CONDUCTED BY ERNEST R. ROOT.

THE BOYS' BEE-HIVE FACTORY.

LESSONS ON HOW TO USE A BUZZ-SAW.

WE left the boys up in the barn-loft, listening to the great drops of rain pattering on the roof. The drops became more frequent until it amounted to quite a shower. It had been very hot and dry, and this rain was not only welcomed by our two young mechanics, but by the farmers throughout the country. The harder it rained the harder it seemed to blow, until Sam and Jimmy began to fear that their windmill would take wings. By the noise the mill was making they knew she was ready to go to work—saw, or do any thing else that her little masters might think proper. Jimmy and Sam could hardly refrain from dancing up and down on the floor; but when their enthusiasm had subsided a little they began to hunt for a good place to hang their lanterns, so that they could see the buzz-saw. Jimmy was just on the point of putting on the belt that connected the buzz-saw directly with the windmill, when he saw Mr. Green, who had just come in.

"Well," said Mr. Green, explaining to the boys, "I felt a little afraid you might get hurt. Besides, it is past bedtime for you both, and growing boys ought never to lose any sleep. I know that three or four hours from your regular amount of sleep does not seem to amount to very much; but I am sure that it does not pay. In view of the fact that you are liable to get hurt here at night, and that it is late, I think you had better postpone your work until to-morrow morning."

"Mebbe we sha'n't have any wind, t'marrer," said Jimmy.

"Yes," said Sam, "we only just wanted to try and see how our buzz-saw worked. You know we have been waiting here for nearly a week; and if we wait till to-morrow morning we run our chances of not getting any wind."

"I feel pretty sure," replied Mr. Green, "that this wind will not die down by to-morrow morning, nor during the whole day. As I came in I noticed that the air was getting considerably cooler. You will notice that the rain has stopped; and when this is the case the wind is pretty sure to continue for 24 or 48 hours. At any rate, I can not think it safe for you boys to work here to-night. To-morrow morning, I will agree to instruct you in the use of the buzz-saw more particularly. In watching the sawyers at the planing-mill you have no doubt imagined that it was very easy to cut boards in two; but as you have never done this kind of work you will need somebody to show you before you attempt it."

The boys reluctantly complied. Jimmy, on his way home, however, grumbled somewhat to himself—he knew he wouldn't get hurt; he could "cut boards in two just as easy as rolling off a log."

The next morning, before breakfast, both Jimmy and Sam were on hand. As Mr. Green had predicted, there was quite a cool breeze—a splendid kite-flying day, so the boys thought; at any rate, their windmill seemed to say, "Come on, boys; you see I am ready again for you this morning. I will work for you to-day for nothing, and board myself."

As was his custom, Mr. Green was up as usual, and so he and the two boys went up into the barn-loft. Jimmy, impatient to see the buzz-saw going, started to put on the belt. Mr. Green, seeing this, called out,—

"You are trying to put the belt on the wrong side of the wheel. You may crowd and try as long as you please, but you will never get it to catch in that way. In putting on a belt while the pulley is at full speed, be sure to put it on the side that is traveling away from the opposite pulley. You then need only to catch the belt to the rim, and it will climb on in a twinkling. It is a real art to be able to slip a belt on to a pulley."

To illustrate his remarks, Mr. Green took the belt in his hand, and let it barely touch the rim. It had hardly done so, however, before the buzz-saw began to whirl and hum. Sam was so eager to try the saw that he got a board and was going to push it against the saw, when Mr. Green objected.

"What do you call them wheels 'pullies' for?" said Jimmy.

"Pulley," returned Mr. G., "is a term used by machinists in distinction from common wheels. I now want you both to try putting on this belt, while I am here to help. Just watch me while I take it off. You see, I am going to crowd it off from the same side I put it on."

Having said this, he took a stick in his hand and bore on one side of the belt till it slipped off.

"Now watch again while I put it on. Sam, suppose you try it," said he, handing the stick to Sam. Sam found it was very easy to take the belt off, but he was not so successful in putting it on again. He tried several times before he succeeded. Jimmy then made an attempt, and with about the same results.

"Now," said Mr. Green, "you are ready to try sawing off a board." So saying he took a figure-four gauge, placed a board up securely against it, and pushed slowly. The windmill and the saw both then went to work, and for the first time showed that they were equal to the task of cutting off boards nice and square. Mr. Green found that the saw would not stand crowding at all, otherwise it would stall the windmill. He then tried some half-inch stuff. The saw would cut through that very easily and quickly.

"Now, Jimmy, you see how well you can do it."

Jimmy grabbed up the board, and proceeded to cut off a length as if he were an old hand at the business. Before he knew it, somehow or other the saw caught the board and jerked it out of his hand.

"What did that?" said Jimmy.

"The trouble was," said Mr. Green, "you should have held the board square against the gauge when the saw-teeth entered the board; for when you began to crowd, it pinched. One of two things had to follow—the saw would have to stop entirely, or else wrench the board away. I forgot to caution you before you tried sawing. At all events, I will say now, be very careful. It not unfrequently happens that men lose their hands, or are knocked insensible, by such a little mishap as that. In the first instance, the saw would so jerk the board as to throw the hand right on the running saw. In the second instance, the momentum which the board would acquire from the saw would be sufficient to knock a man down if it should strike him right, and possibly even kill him."

Jimmy tried it again and was more successful. Then Sam tried his hand. In view of Jimmy's mishap he was even more successful.

"Hark!" said Sam. "I guess ma is calling us to breakfast."

"Yes," said Mr. Green, looking at his watch, "it is high time now."

After breakfast, Jimmy and Sam, along with Ted, climbed up into the barn-loft. They then waited for Mr. Green to come up and give them further instructions. In the mean time Jimmy tried his hand at slipping on the belt, which he did with entire success. Just then a teamster from the mill called out at the barn-door below. He had just come with a load of lumber, which Mr. Green had ordered for the hive-stuff. The two boys hastened down, leaving Ted upstairs with the buzz-saw running. As there was not room above in the barn-loft for very much lumber, Mr. Green had arranged a place in an unoccupied stall below. Here the boys were engaged for a few minutes in taking indoors and piling the lumber in said stall. When the boards were all neatly stacked up, Jimmy heard a giggling upstairs; then a sharp click, as if window glass were breaking; another giggle, and another sharp click.

"My!" said Sam, just recollecting himself, "we left Ted upstairs."

"That's so, by cracky!" said Jimmy.

So saying, the boys hastily clambered up

into the barn-loft. As they got upstairs Ted was laughing, and saying, "See 'em zip." The buzz-saw was humming at full speed; and with a bundle of sticks in his hand, every now and then he would drop one on the teeth of the saw. With the acquired momentum of the teeth, the sticks shot across the barn like bullets, traveling at the rate of about three thousand feet a minute. Some of the sticks had hit Jimmy's and Sam's window, which our readers will remember they had fastened into the side of the barn, right over their work-bench.

"Just see 'em zip!" said Ted, before the boys could interfere; and another stick went whizzing across the barn, nearly hitting Sam.

"Look here, you little brat," said Jimmy; "who said you might do that?"

"Nobody," said Ted; "just see 'em zip;" and another stick went whizzing, and another little hole was made in the window.

Jimmy was so enraged that he grabbed his little brother by the nape of his neck, and hustled him downstairs about as fast as he knew how. Ted then began to set up one of his roars. He wanted to go back and shoot some more sticks.

"No, sir; you won't go up into that barn again in a hurry, I guess. I never can take you anywhere but you're into some sort o' mischief." So saying, he hustled him off home. Jimmy's mother came out, and was prepared to give him a scolding. Jimmy had got used to them, and so did not mind it. After his mother had said all she had to say, he hurried back, to find Sam mourning at the loss of his window.

"My!" said Sam, "if that stick had hit me I believe it would have gone right through me. Why, just look there! It went clean through that window, making a nice round hole."

By this time Mr. Green came in. Upon the boys' telling what had happened, he said that was pretty dangerous business. It was a wonder that some of them did not get seriously hurt—more than all, that Ted had not cut his fingers, or got caught in the belt. He did not blame Ted, but he did blame the boys for being so forgetful and careless as to leave so small a boy alone near running machinery.

Continued Sept. 15.

JUVENILE LETTER-BOX.

"A chiel's amang ye takin' notes;
An' faith, he'll prent it."

A YOUNG QUEEN.

How long will a queen live without attendants? I put a young queen in a cage at about five o'clock in the afternoon, June 30, and she lived by herself until some time in the night of July 2.

LEE W. WRIGHT, age 12.

Palmyra, Mo., July 8, 1887.

A queen by herself will not live very long; but if she has a few bees with her, and a little Good candy, she will live from a week to two weeks.

A SELECTION.

Listen to the honey-bee
As it dances merrily
To the little fairies' drum
Humming, humming, humming, hum.
Never idle, never still,
Humming, humming, hum.

GEORGE ELLISON.

Stateburg, Sumter Co., S. C., July 22, 1887.

HOW PA TAKES DOWN A SWARM.

When my father has a swarm up high in a tree he takes a long pole and fastens a box to the end of it, then he raises it up; and when the box is under the swarm he bumps it up against the limb till the bees fall into the box, then he lowers it and puts them into a hive he has ready.

ERNEST C. HILTON.

Los Alamos, Santa Barbara Co., Cal.

LOVING JESUS.

I am seven years old, and I go to Sabbath-school. I wish all little boys and girls who go would try to get those to go who do not, and learn to love Jesus. I think it is in Sabbath-school they will be taught to be good, and to do good, and help others to learn of Jesus. Jesus said, "Suffer little children to come unto me, and forbid them not; for of such is the kingdom of heaven."

FRANCES NELSON.

Talley Cavy, Pa., Mar. 18, 1887.

FOLDING SECTIONS.

I put sections together at the rate of 660 per hour. They were the one-piece sections. Pa has about 40 stands of bees. I have one. They have not swarmed this year. They are all Italians. They made no honey last spring, but are getting some from sumac now.

CHARLES WELTY.

Nashville, Mo., July 21, 1887.

Try again, friend Charlie, and see if you can not equal the record of Nettie Cranston, as recorded on page 550, July 15th. If you turn back you will see that the little girl has nearly doubled your rate of folding.

ESTHER'S LETTER.

We drained our fish-pond, and did not find any carp. The clover is yielding very little honey, on account of dry weather, but we are getting some rain now. The fog is very heavy, and the little chickens don't like it. They make a very loud peeping. Lem wants to go out and see what is the matter with his chicks. He has the chicken-pox, so he dare not, but he doesn't know it. The strawberries all dried up, but the grapes are fine. The Concorda are the largest, but the Vergennes and Pocklington have the least foxiness on the grape.

ESTHER TRIEDLEY.

Silver City, Iowa, July 2, 1887.

THE MOSQUITO HAWK.

Pa has two hives of bees. Brother George has five, and I have one. We keep our bees in what is called the Golden bee-hive. Pa says he does not like it, because the top story is too small. He knocked off the bottom of the bottom story, and put it on one of his hives instead of the small top story. I am the one who attends to the bees and takes the honey. What is called the "mosquito hawk" is a great enemy to the bees. You see them every evening flying around the hives, and now and then you see one catch a bee and go off. I like to work with bees when they are not too cross.

Johnsonville, S. C., May 12, 1887. S. O. EDDY.

HOW TO TAKE A SWARM DOWN FROM AN APPLE-TREE.

I should like to tell that other Fred (see page 68) how to take bees down from the tops of apple-trees, without getting stung. Fasten the swarming-box under the cluster, as near to it as possible. Take one end of a ball of wool-twine, climb the tree, tie the twine around the limb just above the cluster, then get down. Take the ball, and go away as far as you please, and shake until the bees are all in the swarming-box, then carry them to the hive.

FRED GILLETT, age 11.

Brighton, Lorain Co., Ohio.

QUICK CAPPING OF HONEY.

My pa takes GLEANINGS, and he said he had never read of honey being capped in three days after it was gathered. But we had some in 1886, and the year before, that the bees began to cap the third day after it was gathered. At the fair, pa talked with a man who had been keeping bees for a long time, and this man said he had "never heard tell of" honey being capped in less time than six days, and we want your opinion. We took 995 lbs. of honey in 1886, and increased from 13 to 19 swarms.

Eaton, Preble Co., O. LOLO R. FLORA, age 13.

I should say it was rather quick work for bees to cap honey over in three days after it was gathered. Honey must have been coming in at a great rate.

DIFFERENCE IN LOCALITIES BUT A SHORT DISTANCE APART.

Our bees have not gathered enough honey to keep them all alive. We have had to feed some. My pa has 48 hives of bees. They are a little weak. Bees all around us are doing well. Eight or nine miles south and east they have had plenty of rain. If it does not rain soon I don't know what bees are to do here.

ROBERT WILLIS.

Jonah, Williamson Co., Tex., July 12, 1887.

Yes, Robert, a distance of only a few miles oftentimes makes quite a difference in the honey crop.

BEES AND FISH.

My pa has a new way of feeding his bees. He takes a little glass tumbler and fills it with syrup, puts on the lid, turns it upside down, and it runs out enough for the bees to eat it as fast as it runs out. Pa is building a workshop and a granary, and he is going to have a room in it to keep his honey to sell. We have three fish-ponds. When pa goes to the ponds every morning to feed the fish he smacks his hands and calls them, and then he throws bread in to the fish, and they come up and eat it. The cranes eat up some of them. Pa saw a crane at one of his ponds this morning. He shot at it, but did not kill it.

SUSIE COOPER.

Traveler's Rest, S. C., July 5, 1887.

THE CATALPA-TREE.

One year ago I made up my mind to have an apiary. As I was only thirteen years old, I bought one colony which has increased to three. The colony which I bought I have transferred into a Simplicity hive. They have not made much surplus honey.

We have the catalpa, or cigar tree, here, and the bees work on them all the time they are in bloom. If you were under the trees it would sound as if there were a swarm going over your head. One of my colonies seems to be very weak. Pa and I look-

ed for the queen, but could not find her. Pa does not know much about bees, but could tell a few things about seeds, for he has been a clerk in that business for 22 years. The last twelve were spent in the employ of Peter Henderson & Co. Last March he came here to the land of peaches and berries to try his hand at fruit-growing.

Redden, Del.

E. S. COMPTON.

BLOOD-POISONING FROM BEE-STINGS.

Mr. J. S. Starn was hiving a swarm of bees for a neighbor, when he was stung twice—once on the nose and once on the chin. In about three weeks he was taken sick. They sent for a doctor. He said it was blood-poison. His throat came very near swelling shut, but it broke and saved his life.

This section is very good for bees. We have fruit-bloom, black locust, white clover, and bass-wood. About half a mile from here is a ten-acre field of alsike. The bees have a regular picnic on it. The honey has the flavor of white clover. We have sweet clover along the roadside. A friend told papa that one cup of honey would sweeten three times as much as much as one cup of sugar.

MACY M. ELLIS, aged 11.

East Monroe, Highland Co., O.

Are you sure, friend Macy, that the bee-stings which Mr. Starn received three weeks before, had any thing to do with the swelling of his throat? The effects of bee-stings are immediate.

A QUEER COLONY.

Pa takes GLEANINGS, and he likes it very well. He says he would rather stop any other paper than GLEANINGS. I like to read the little juvenile letters. We have one colony of Italian bees. Our bees swarmed four times this summer, so we have five colonies in all. Our bees swarmed very queerly. The 12th of June a swarm came out, and they all went back into the hive again; and 11 days after that they swarmed again, about 9 o'clock, and went back again in the afternoon. They swarmed again at 2 o'clock, and clustered on an apple-tree near their hive; the next day at 9 o'clock they swarmed again, and clustered on the same apple-tree. The next day at 10 o'clock they swarmed and clustered on a little cherry-tree; two days after that they swarmed, and clustered on an apple-tree, and after they were hived a little while they all went home again. Two days after, they swarmed again, about half-past 8, and they are all doing nicely now. Pa winters his bees down cellar. He made a Hill device for them, and they came out nice in the spring.

KATIE M. ZEHR, age 12.

Indian River, N. Y., July 17, 1887.

Your colony, friend Katie, behaved itself in rather an unusual manner. Do we infer that they returned to the parent colony as often as they swarmed?

SWARMING, AND THE SERVICE THE LITTLE FOLKS MAY RENDER; HOW A QUEEN LOOKS AFTER SHE IS STUNG.

We have 85 colonies, and sometimes it is lively with them. One day seven swarms came off at once. When the swarm is small, pa puts two together or takes the queen, and then the bees go back into the hive. Two days ago a little swarm came off, and pa found the queen after they had alighted. They stayed on the tree. He looked after and found another queen. We put them both under a goblet. They caught each other, and one of them stung the

other. She doubled up like a burnt shuck, and in a little while she died. After pa got the second queen he shook the bees off, and then they settled in three or four places. All of them went back in the hive, except about a tea-cupful. The next morning Edith took a strawberry-box and put them in it; then she asked pa to look at her swarm, and there was a queen in it. He made her a little hive, and she put them into it. Pa gives ten cents a swarm to the one who sees or finds it first. I have found 12, Edith 13, Fred 6, Grace 2. Pa generally finds them first. He chewed tobacco for 25 years, but he quit four years ago. He says he feels much better now, than before he quit chewing.

JASPER D. TRACY.

Longmont, Col., July 11, 1887.

Thank you, friend Jasper. Your father's plan of paying his children ten cents for every swarm they discover first, and report, is a good one. Have you all learned the swarming-note, so that your ears tell you what your eyes may expect? I should like to know how many of you can tell the robbing-note—that high key, or angry hum. It seems to me that, if one of you find a case of robbing before any one else, he ought to be rewarded with—well, say 50 cents. Perhaps even a dollar would not be too much, where the consequences might have been rather serious. Beginners often find it difficult to detect robbing at its start; but practice will soon enable them to tell every time.

THREE LITTLE TURKEYS, AND THEIR STEPMOTHER.

Mr. Editor:—We had two hens hatch chicks at the same time. All the chicks were given to one hen, which were placed in a coop at the apiary, some distance from the barn, where the hatching occurred. The hen whose chicks had been removed stayed around the nest for two days, clucking for her lost babies. At this time another hen in the yard gave indications of weaning her brood of turkeys, which had dwindled to three. They were four weeks old, and their big mouths had seemingly disgusted the hen. At evening she left her three little turkeys. The hen which was bereft of her own natural brood was sitting on the empty nest where she had hatched.

I said to my wife, "Let us try an experiment."

We placed the three little orphaned turkeys under this hen. She uttered two or three notes which seemed to say, "Take care, now," as though not well pleased. But it was near dark, and all became quiet. In the morning the hen was found using most assiduous motherly care over the three little turkeys, which were very offish, and reluctant in accepting the profuse attentions of their new stepmother. The hen which had hatched and cared for the turkeys until they were four weeks old did not come near or recognize them, and in a short time the persistent attentions of the new stepmother overcame their turkish prejudices, and they very soon became cordially the most loyal little turks on the ranch. Their stepmother would attack any animated nature, from a half-grown chicken to a full-grown cow, which would chance to come near her turkeys. For three weeks there has been no abatement of the care these little turkeys have had from the hen which adopted them. Is this case a result of reason on the part of the hen, or of strong natural instinct? It looks like reason. Who can answer?

JOHN CADWALLADER.

North Indianapolis, Ind., July 17, 1887.

OUR HOMES.

For where your treasure is, there will your heart be also.—MATT. 6: 21.

Though I walk through the valley of the shadow of death, I will fear no evil.—PSALM 23: 4.

CONNIE and Caddie and I took a two-days' vacation. They are aged respectively fourteen and nine, and I had long talked with them about showing them the home of my boyhood; and I wanted especially to show them the beautiful soft-water springs that gush out of the hillsides and rocks of old Summit County. Well, we found the springs; and as it was in the midst of an August drought we enjoyed them, I assure you. But as I shall have a special article on springs ere long, I will not tell you about them just now.

In visiting a relative, by chance I met an old schoolmate. We hadn't seen each other for more than thirty years. My recollection of her was of a good-natured, light-hearted schoolgirl, and, to tell the truth, I had so nearly forgotten that such a person existed I had to make an effort to refresh my memory before I could exactly locate her. Then we talked about the old school-house, and of the time when the trustees decided to build a better one, and of the various other events that happened when we were careless, heedless children. Then the intervening years were gone over. The talk lasted from twenty minutes to half an hour, and during that interval several times the thought came into my mind as to whether this old schoolmate was a Christian, and were her hopes centered in Christ Jesus? I thought I would bring the subject in before I went away, but there did not seem to be any good opportunity. When she smiled she looked much like the girlish schoolmate of former days; but when the smile had passed there was a look somewhat akin to sadness; and this look, with the gray hairs and occasionally a wrinkle, seemed to indicate that she had had her trials and sorrows as well as the rest of us. I tried to think of some way of broaching the subject of the Christian's hope; but others were present, and I was afraid they would think me eccentric, or odd. Now, I do believe, friends, that it is a Christian duty to avoid eccentricity, and especially to avoid any thing that would look as if we wanted to attract attention to our peculiarities. A Christian should strive to have his life count all it possibly can, and he can not take any risks. I am sure, however, that *Satan* often offers these suggestions, that we shall do more harm than good by speaking out, and I feel sure it was so in this case, because, as I passed out through the beautiful dooryard, a weight of gloom rested on my spirits because I was going away without speaking a word for the Master. I did not tell her of the great change that came into my life during about the middle of these thirty years. I did not tell her of the joyous inspiration that makes life worth living, and that comes to every one whose hopes are founded, not on self, but on Christ Jesus. Conscience whispered, that Caddie and Con-

nie, for whom my wife and I have been praying so much, might get an impression, from the talk they had listened to during these twenty or thirty minutes, that all there is in this life is to go along quietly and take good and evil as they come, looking on it all as an idle show, or like some simple panorama for our entertainment. I don't think they could have gathered any thing from our talk, to the effect that either one of us regarded life as a sacred and solemn gift from God, or that we regarded it as a great and inestimable privilege to live, and to work for the upbuilding of mankind. The memory of that face comes back to me over and over again; but the opportunity was allowed to slip by, and may never come again. If it does, I am going to tell her how sorry I felt that I did not tell her of the new-born hope that had come into my life in middle age, and made this world—nay, the whole universe—so intensely real, because, during the last part of my life, I have been living for something, while before I was living for nothing or worse than nothing—for self and selfish purposes, and for selfish ends.

This friend had heard of me during these years, and had no doubt heard that I was an earnest and enthusiastic Christian. I can imagine that she might say, after I had gone, "Why, I've heard so much about Mr. Root's Christianity, and that he never lost an opportunity of speaking to every one about their soul's salvation. I did not see any thing about him different from people generally, or people of the world. There was nothing in his looks or actions, and surely not one single sentence in his talk, to indicate that he had any such faith or earnest convictions as I have heard about." If my treasure was in heaven, why did not my talk have some reference to it in some way? In other words, why did she not see that my heart and soul were where this treasure was also? It was because I didn't act natural. I had somehow got it into my head, that, when I met old friends, the way to do was to make a sort of fashionable call, as people generally do. My friends, it is a blunder and a mistake, and I will tell you how I know it.

It had been so many years since I visited my relatives whom I proposed to call on next, that I was obliged to ask directions. I didn't understand the directions, or, rather, I didn't listen very carefully, and so I called at the wrong house. By the way, Connie says I was stopping at the wrong house every little while. I told her it didn't matter, any way, for they were all our neighbors at all houses, and that I liked to see folks, and talk with them, even if they were entire strangers. When I suggested that we had reached the place, she demurred.

"Why," said I, "the lady said one cousin lived on one side of the road, and another cousin on the other side, and here are the two houses on opposite sides of the road. Besides that, see those chaff hives so nicely arranged over there. We can not be very much mistaken in calling where there are bee-hives."

Accordingly, we three passed up the shady

gravel walk: and just as I got before the screen-door, whom should I meet but a very dear friend whom I supposed at the time was away off in Michigan? She laughingly welcomed us, saying at the same time she was pretty sure I made a mistake or I would not have called there. Connie laughed too, declaring it was really so. But it was not a very bad mistake after all, for the place was owned by still another relative, and one of the younger ones owned the bees. The family were all away, however, except the two ladies, and with these I had a most pleasant half-hour. I had the same feeling as before, and I had also been waiting for an opportunity to speak with them in regard to the matter that was nearest my heart. I hope, dear reader, I can truthfully say, a matter that is always uppermost, whatever may for the time being take my attention. The opportunity came in this way: One of the ladies, who was a bee-keeper, asked if I had ever heard of any one swallowing a bee. When I replied in the negative, she remarked that their hired man had, a few days previously, swallowed one while drinking. He was watching his horses at the time, and drinking hurriedly, and therefore did not see what he had done until he felt the bee stinging him part way down his throat. He came to her in great trouble, and asked what had better be done. Although she was not very positive, she instinctively guessed that the safest thing would be not to alarm him needlessly; so she assured him there was little probability of its giving him any trouble at all, and thought he need not feel any anxiety in regard to it. He accordingly went on with his work, and it turned out as she surmised. I was at first startled when she mentioned the occurrence, and remarked that I should have feared, more than any thing else, the danger from swelling so as to cause suffocation. Perhaps many of the readers of GLEANINGS may remember a case that was reported in England, of a man who was strangled to death by being stung by a bee in his mouth or throat. The talk then turned on the importance of being cool and self-possessed when things of this kind come up that may cause fright, and I told the ladies of a little experience of my own which had a moral to it; and as this moral may be profitable to you also, I wish to tell it here:

As long ago as when I was a boy in my teens I was, and have been since, troubled with a chronic sore throat. The first time I was alarmed by it I was sleeping alone in my store. While sound asleep, an irritation in my throat caused a spasmodic closing of some part of the respiratory organs. I sprang to my feet, and for a few moments it seemed doubtful whether I should ever be able to force my breath again through the passage that had closed so strangely and so suddenly. During that time I mentally faced death. I thought of dying alone by myself, before I could manage to call anybody, and make myself heard, as there were none very near. Dear reader, at that time I had no faith or hope in Christ Jesus. I was taking care of myself, and doing as I pleased; but when I stood at death's door, I

felt troubled, I tell you. You know how the mind reviews events at such a time. My past life passed before me with lightning rapidity. I summoned all the courage I could, and tried to face the issue, but it was hard work. There was no comfort anywhere. I was away out at sea, in utter darkness. No gleam or ray of hope showed itself in any direction; no friendly arm was near me to lean upon. After some pretty hard struggles for the breath of life, the spasmodic action passed away, and I could breathe, though with difficulty, once more. Ever since that moment I have realized what a privilege it is to be able to breathe easily and without pain. I wonder now that I didn't say "thank God" when the danger was passed; but as I didn't recognize any overruling power then, there was nobody to thank. Of course, I consulted a physician at once. He prescribed cauterizing the throat with nitrate of silver. After submitting for several months to the painful treatment, resulting in no perceptible good, I tried other physicians, and have been trying. My opinion now, however, is, that honest hard work in the *open air* has been worth more to me than any doctor.

Some years afterward, in consequence of a slight cold, this throat trouble again began to be acute. In the middle of the night my breath stopped again short and suddenly. I sprang from my bed and got out on the floor, and tried in vain to open the passage that had been shut by the spasmodic action. By an effort that made the sweat come from every pore in my body, a very little air could be forced in and out of my lungs; but it was evident that life could not last long in this way. Again I was obliged to face grim death. For a time I was frightened and demoralized, and forgot every thing except the intense and all-absorbing fight for breath. No one except him who has passed through such an experience can understand it. I not only felt that I would have given worlds for the privilege of breathing free again, but I felt that I *must* have breath. I tried to reconcile myself, and submit to death, if my time had come, but there was no submission. It seemed as though a long time elapsed, but I presume it was only a few brief seconds; but amid the agony (*mental* agony, for as yet I had suffered but little, comparatively, physically) came that little prayer, "Lord, help." In an instant a feeling of thankfulness (that is, thankfulness compared with the former darkness) began to well up that there was help and aid; and while I prayed for breath I prayed also for grace to submit, if it were the Lord's will that I should never draw breath more. It was a battle between self and Christ—much such a battle as I had fought many times before. But Christ triumphed, and comparative peace came—not that I was willing to give up life, by any means, but I felt willing to submit it to the Judge of all the earth, feeling sure he would do all things right. My wife was near me, shaking with excitement and sympathy, especially to think that she was powerless; for different physicians had told us before, that nothing could be done in such cases. I

kept straining every nerve, to force a little air through that shut-up passage; and as the peace that only God can give under like circumstances began to come into my soul, the stubborn muscles began to relax a little. And can you, my friends, think for a moment how I rejoiced to feel that terribly labored breathing begin to come and go a little easier? In a few moments I could breathe almost naturally; but my lungs and windpipe were smarting as if they had been torn and lacerated by the terrible muscular effort. I began to think after that, that fright had much to do with it.

Some time afterward, while in the apiary, I was stung on my neck. It was a pretty bad sting in a very tender spot, but I thought nothing of it until I began to feel a swelling in my throat, and symptoms of a closing of that terrible air-passage. Already a wheezing sound that announces it, had commenced. Something whispered (is it possible that it was Satan?) that now I should die, sure. If my throat became swollen from the effects of a bee-sting, I should surely die as the poor friend who has been spoken of over across the water died. I felt weak and faint. The blood rushed to my face, and the sweat began to pour forth again. This time, however, I had grace enough to say promptly, "Get thee behind me, Satan. I am trusting in the Lord Jesus Christ, and he has power not only to still the winds and the waves, but to raise the dead if he choose. I am in his hands; and whether I die or whether I live, blessed be his holy name."

The fright and excitement began to abate, and, to my great relief, the spasmodic action of the breathing-apparatus also began to subside; and, my friends, although I even now thank God for the privilege of free and easy breathing, I thank him a thousand times more for the privilege of feeling safe and secure, no matter whether it be through life or through death. I have had one experience in facing death alone, with nothing but midnight darkness and gloom—with no hope or faith; and I have had another, with the comforting feeling that the great God of the universe is always ready, and always watching over the children he loves, if they will only put their trust in him.

Are not two sparrows sold for a farthing? and one of them shall not fall on the ground without your Father.—MATT. 10: 29.

The point comes in here, that suggests that many times people lose their lives by the excitement caused by fright or the effects of imagination. Physicians have already told us much about cases of this kind. Well, if this be true, a faith in God does much—yes, very much—to prolong life.

The Lord is my light and my salvation; whom shall I fear? The Lord is the strength of my life; of whom shall I be afraid?—PSALM 27: 1.

Now, when my cousin told of the experience of the hired man, and that she assured him there was little probability that any harm would come from it, she did a wise and kind thing. People may be so frightened as to very much aggravate the danger of a bee-sting, and, if I am correct, the danger of many other diseases may be averted by a quiet, peaceful trust in the Lord, es-

pecially in matters where we are helpless. My friends were both professing Christians; and when I told them of my experience, as I have told you, I was pleased to notice how their countenances lighted up. We then had many talks of God's kindness in times of severe trial, and this opened the way to something in regard to faith in prayer. When we parted we had all been strengthened in our Christian experience; and I believe the result of that half-hour's talk will cause us to remember, as long as we live, that we are not only related by flesh-and-blood ties, but through the love of Christ Jesus, the friend of humanity. At the close of my first visit I went away feeling sad and self-condemned. I went away feeling cold and indifferent, and away from God, and, I am afraid, with a smaller amount of faith; but after this last visit I passed down on their beautiful walk under shady trees, with a feeling of gladness and thanksgiving and praise in my heart—with a feeling that no words could express, and no tongue tell, of the comforts that come to those who are striving to lay up treasures in heaven rather than on earth, and with a feeling that I can hardly describe, but something like this: A feeling that it is indeed true, that God has placed it in the power of each and every one of us to strengthen the faith and hold up the feeble hands of those round about us; that during a half-hour's visit we may talk of the world and of worldly things in a way that will encourage the feeling that this world is all there is to live for; or, on the contrary, we may, in even one half-hour, raise ourselves and those about us to a contemplation of spiritual things that shall infuse new energy; that shall give inspiration in the pursuit of these things in every-day life; that shall ennoble and lift up, and help all to take another step heavenward.

A trust in Christ contributes to make us brave in life and brave in death; and this bravery is not of the defiant kind either, but it is a trusting and confiding courage. Jesus braved death when it was constantly in his power to sink his enemies into oblivion; but putting all thought of self and of bodily suffering out of the question, he died that his enemies and persecutors might live. It was as hard for him to die as for any of us; and with human weakness he shrank from it just as we would. Indeed, at one time he uttered the words, "My God, my God, why hast thou forsaken me?"

Now, my friends, if this talk to day has been the means of helping you to trust in the time of trial in the kind Father who placed us here for his own wise purposes, I shall feel glad and happy that I have given you this little bit of my experience; and I know, friends, by personal experience, that there is no comfort and no satisfaction in encouraging skepticism and unbelief; while I do know, also, that he who trusts in the Lord has his feet planted on the solid rock; and the comforting thought may be always in his heart, no matter what dangers threaten.

Though I walk through the valley of the shadow of death, I will fear no evil; for thou art with me; thy rod and thy staff they comfort me.—PSALM 23: 4.

TOBACCO COLUMN.

ITS ORIGIN, AND HOW INTRODUCED TO CIVILIZED NATIONS.

FROM one of my books I copy the following: "Until the discovery of America, the tobacco-plant was unknown to Europeans. The sailors who accompanied Columbus noticed the natives puffing smoke from their mouths and nostrils, and soon learned that this arose from the smoking of the dried leaves of a plant." I suppose the Europeans thought that what was good for Indians was good for them, so they picked up their filthy habit; but they knew no better. I like the description King James gave of its use; he said, "It is a custom loathsome to the eye, hateful to the nose, harmful to the brain, dangerous to the lungs."

Think of the many thousand who will go to the bottomless pit through tobacco. I wish more would try to do what you are doing, and may God be with you in that work. "The poisonous nature of tobacco is mainly due to one of its elements called nicotine. This is a deadly poison. Experiments show that two drops, placed on the tongue of a fowl, causes death almost instantly." That fact alone ought to persuade them to stop; but they are such slaves, and their will is so weakened, they don't.

I have a neighbor who, I think, would not stop its use for one hundred smokers. What we want is to keep the younger ones from it. The older people won't last always.

There is not much use of repeating it, for nearly every one knows that "tobacco, like alcohol, injures the brain, deranges the entire nervous system, spoils the appetite for wholesome food, lowers the life forces, injures the lungs and heart, and depresses the spirit. When indulged in by young persons it saps the foundation of health, and dwarfs the body and mind."

"It is rare to find an inebriate who does not use tobacco; and careful inquiry will prove the statement that, in nine cases out of ten, the tobacco habit was first formed." Keep the young from it if you don't want them to be drunkards.

Wayland, N. Y.

W. A. LAWRENCE.

I have quit using tobacco; and if I ever use it again I will pay you in full for a smoker.

New Portage, O.

ISAAC FRITZ.

I have quit using tobacco, and never intend using it again. If I should I will pay the price of the smoker.

Walla Walla, Wash. Ter.

H. W. BUFFUM.

I hereby promise to quit the use of tobacco in every form; and if you send me the smoker, and I use tobacco again I agree to pay you for the smoker.

Wise, W. Va.

ELI COLLINS.

I have quit the use of tobacco altogether, after using it for 15 years, and I expect to stay quit. If I am entitled to a smoker, send me one; and if I begin again I will pay you in full for it.

New Florence, Pa.

GEO. R. STEWART.

I used tobacco for twelve years, but quit about two months ago. If you will be so kind as to send me a smoker I shall be ever so much obliged; and if I ever go to using the weed I will pay you your price for the smoker.

Montevallo, Mo., July 20, 1887.

N. F. CRIFE.

Mr. W. W. Hallenberger says he will quit the use of tobacco if you will send him a smoker. He will pay for the same if he resumes the use of the weed.

Sherwood, O.

P. E. KINTNER.

I have quit the use of tobacco, and I should like to have a smoker. If you will please send me one, if I ever use tobacco again I will pay for it.

Ambrosia, La., July 2, 1887.

W. A. WALTERS.

I have quit using tobacco; and if you think I should have a smoker, send me one; and if I ever recommence the use of it I will pay you for the smoker, and I will try all I can to get others to quit the filthy weed.

J. SULOUFF.

Cocolamus, Pa., July 2, 1887.

I began using tobacco three years ago, for the purpose of smoking bees; but I found it injurious to my health, and I quit the use of it. If I am entitled to a smoker, send it along, as I promise never to use tobacco again. If I do I will pay you for the smoker.

E. MCCLAIN.

Potosi, Wis., June 20, 1887.

My uncle has been a slave to tobacco for 11 years, but quit the use of it about 7 months ago, and would be pleased if you would send him one of your smokers; and if he again takes up the use of it he will pay you for it. His name is J. E. Ried, Greensboro, Greene Co., Ga.

T. E. RIED.

Greensboro, Ga., July 2, 1887.

I have been thinking of quitting tobacco for some time, but could not get exactly ready to make the commencement. Now, if you will send me a smoker I will promise faithfully to never chew any more of the filthy stuff; and should I ever use any more I will pay you \$1.00 for the smoker.

Luttrell, Ala., July 1, 1887.

S. C. STONE.

I quit using tobacco the 12th day of March, 1884, and have not used any since, and I never intend to use any more. If you think I am entitled to a smoker, I should be very glad if you would send me one; and if I should ever use the weed again I will send you the price of the smoker.

J. OFFUTT.

Derden, Tex., June 22, 1887.

ANOTHER NAME FOR THE TOBACCO COLUMN.

Mr. A. Y. Gulley, 60 years old last May, has been using tobacco for 50 years, and he now promises to quit if you will send him a smoker, and to pay for it if he ever uses tobacco again. He was so unfortunate as to have his house and nearly all it contained burned up a short while ago; and among his other losses were several colonies of bees. He saved one colony only; and as he is very fond of bees he hopes to get a start again.

WM. E. CUNNINGHAM.

Hartwell, Ga., June 13, 1887.

It has been a long time since I wrote you. I want you to send Ben Miller, Oakland, Colorado Co., Tex., a smoker. He promises to quit tobacco, and also promises to pay if he uses it again. He can not write, and therefore requests me to write for him. Also please send one to uncle G. R. Berry, Lampasas, Lampasas Co., Tex. He is an old man and well to do, and says he is able to pay for a smoker; but if he takes the pledge and the smoker as a reminder, it will help him to fight the battle.

AMANDA ATCHLEY.

Lampasas, Tex., July 9, 1887.

OUR OWN APIARY.

CONDUCTED BY ERNEST R. ROOT.

FOUL BROOD.

AS I promised in our last issue, I will now proceed to give further facts in relation to foul brood; but before doing so I must preface a little.

I have found it *exceedingly* difficult to arrive at any thing definite. Certain pet theories, the truth of which I thought I had or could establish, I had to abandon. Over and over again I have had to change my mind, until absolute certainty seemed well nigh unattainable. Inferences based upon insufficient or false data have done not a little to make our knowledge upon the subject of foul brood perplexing and uncertain. In view of this I have tried to report only such as I felt satisfied at the time were facts and not feebly supported theories. For the same reason I have hitherto not thought it best to say much concerning acid treatments which I have been trying for the last three or four months. It is with some hesitation that I consent to do so now; and were it not for the fact that my present knowledge of carbolic and salicylic acid treatments might render assistance to some brother bee-keeper experimenting in the same line, I would refrain from making any mention of them until I had fully satisfied myself as to whether they were effective or not.

THE CONSIDERATION OF DIFFERENT METHODS OF CURE.

Complete extermination by fire, of a diseased colony and all its belongings, is effective as far as the cure of the colony *itself* is concerned; but in burning up a colony it is next to impossible to destroy *every* bee. One, and more probably a dozen, inmates of the diseased hive will get back to its old stand. Of course they will enter the nearest hives and so carry the infection. Aside from this, complete extermination is too expensive.

THE STARVATION PLAN.

While this method is also effective as far as the cure of the colony *itself* is concerned (notice the italicized word), yet the disease is spread in much the same way as the first case; that is, the bees on being put back into entirely different quarters on their old stand will naturally seek to find their old brood-nest in others adjacent to their old stands.

I have referred to this intermingling of bees once before; but it is nevertheless a fact, and it has been demonstrated over and over again. In a word, then, my objection to the two plans of treating a colony just mentioned, is, that, while a cure is effected for the colony *itself*, yet the cure is at the expense of giving the disease to the neighboring hives.

TREATING WITH CARBOLIC ACID.

Well, then, now to the point: We want a method of treatment which will not only cure the colony itself, but prevent the *spread* of the disease to *other neighboring hives*. With this end in view I have been experimenting with salicylic and carbolic acid.

Our method of administering the acids is somewhat different, I believe, from the methods usually employed. I will first speak of carbolic acid.

This, as far as we are able to observe up to this writing, *seems* to prevent the spread of the disease to neighboring colonies; and we think, when properly administered, it checks the disease in the hive itself, and finally cures it. Our method of treatment was only briefly outlined in our last issue. Since then we have modified the plan somewhat, and I will therefore recapitulate in part.

Get a bottle of pure carbolic-acid crystals. Be sure that the latter are white. Your druggist may try to convince you that the yellow are just as pure; and if he does not have the crystals he may try to sell you the liquid. Get what you call for or none at all. The bottle which I got will hold nearly a quart of crystals, and cost 50 cts. This amount will make over a barrel of liquid when reduced for the bees. Having procured the crystals you are to dilute them by weight, avoidupois. I say avoidupois, because this will be more convenient. With a pair of accurate scales, weigh out exactly one ounce of crystals. The easiest way to do this is to place the receptacle (a small teacup, for instance) on a pair of scales with which you can take out the tare of the cup. Place the bottle in the sunlight, or near a stove, and let a few of the crystals melt. Now pour into the cup until the scales show exactly one ounce. The crystals, when melted in the cup, should look a little yellow and oily. Having done this, weigh out 500 ounces (31½ lbs.) of water. Heat it, and then thoroughly mix the ounce of melted crystals with the water, and allow it to cool.

After sundown, open your diseased hive and uncap every single brood-cell of all the combs, whether diseased or not, with a wire brush or coarse comb. Be careful not to mutilate the larvae any more than necessary. You must rake the cells open, not strike the brush into them. With a spray-diffuser, spray a fine mist over the bees, brood, and the entire inside of the hive.

Be careful not to get too much on the bees and brood. By no means drench them, or you will either kill the bees or cause them to leave the combs and cluster on the outside of the hive. The robbers are then pretty sure to take possession and — you know the rest — your labor is for naught; nay, you are a great deal worse off than before.

I have tried yucca brushes to paint the combs and for spraying bees. I have tried using a watering-pot; but these drench the bees so that the results are apt to follow as I have described. The only thing that you can use with any degree of success is an atomizer. In three or four days after the first spraying, spray again, but do not uncup; and so on for a couple of weeks.

To those of you who can not get an atomizer, we will furnish you one for spraying a few colonies, for 75 cts., or 10 cts. extra by mail.

If you can not get the carbolic-acid crystals you call for, write us. We can not state yet what we can furnish it for.

Now, my dear reader, I have given you full particulars in regard to the treatment of diseased colonies with carbolic acid. Although the acid treatment has so far been very promising, I am not sure that even that will be an ultimate success. Remember the point in its favor so far is, that it prevents the spread of the disease into other healthy colonies. I shall have something further to say about carbolic acid in our next issue, and also give the reasons why I prefer carbolic acid to salicylic.

ROBBERS.

In consequence of the great scarcity of nectar and the dry weather, robbers are most persistent in their efforts to steal. We manage to get along in the daytime after a fashion, with the tent, but the little thieves have learned the trick of dropping down in the grass around the bottom fringe of the tent and crawling under. We are obliged to do some of our work by twilight.

HONEY THAT FOAMS IN THE CELLS.

WHERE DID IT COME FROM?

I SEND you by this mail a sample of honey. Can you tell what it is? Is it of the celebrated bark-house variety—something I never saw? In case it is not, what then do you think of it for wintering?

The honey season has been a poor one; very little clover, and no basswood at all. July 12th I extracted what I thought would save the bees from starving during the honey-dearth, which generally sets in about July 15th and lasts till late in August. But in spite of the honey-dearth, my bees went to work with a will. Then the combs soon began to fill, and the honey looked nice and transparent in the comb; but as I came to extract it I found it dark. My first thought was honey-dew; but when I hunted up the description of the latter I began to think mine is not dark and bitter enough to be the real stuff. But, however, it is the queerest thing I ever saw. When first gathered it foams in the comb, like soapsuds, and some swarms hang outside for lack of room, and, in reality, they have nothing in the comb but a little foam. They draw the cells up, cup-shaped, and then put a convex cap on it, as on drone brood. When I pull the capping off there is nothing but a little foam in the cell, hardly enough to form a drop. Others, however, work it in a more business-like manner. They fill the cells full, avoid fanning, to a great extent, and cap the cells in the ordinary way. I have tried to trace the bees, but generally lose sight of them when they approach the woods and marsh, but I am a good deal of the opinion they are in the marsh or else go across it.

J. JOHANNSEN.

Port Clinton, O., July 27, 1887.

Friend J., the sample you send may be honey-dew, or the secretion of aphides; but if so, it is lighter in color, and rather better in flavor, than the general run of aphid honey. I have before heard of honey that foamed out of the cell, and I believe this has often been the case during our wintering troubles and spring dwindling. If the honey finally settles down, and is capped over, with the cells full of thick solid honey, I think I would risk it: if it remains foamy, I do not believe I would.

KIND WORDS FROM OUR CUSTOMERS.

The goods came to hand to day. They beat any thing I have ever seen in that line. A. BAGLEY.
Siloam, Ark., Aug. 8, 1887.

Goods are at hand, and we are much pleased. Mrs. K. says she thinks your profit is small on the 25-c. socks, for 50 cts. would not more than buy such hose here. MILTON KNOWLES.
Crystal River, Fla., Aug. 2, 1887.

My little adv't in last GLEANINGS has brought all the orders that I can possibly fill. I very much dislike to cut down prices of queens, but I thought that dull times and poor honey seasons demanded it. Please announce that I have no more queens to spare. WALTER POWDER.
Groesbeck, O., July 14, 1887.

THOMAS HORN.

In the Thomas Horn case I fail to see where you have been at fault; and your offer of settlement must satisfy the most unreasonable ones. I sent Horn \$1.00 for a tested Italian queen, and received nothing. I am not willing it should be your loss, so please mark my claim settled.

E. VAN FRADENBURG.

West Fulton, N. Y., July 26, 1887.

PAYING ANOTHER'S DEBTS.

I wrote you yesterday, ordering queens on Thos. Horn's account; but after due consideration I can not see how any man can consistently ask you to pay Horn's debts, and I do not think that any one can honestly hold you responsible for them. Now, then, I countermand my order, and thank you the same as though I had received the bees.

Edgerton, Kan., Aug. 2, 1887.

B. T. DETAR.

CHEAP AND GOOD. THAT MAPLE SUGAR.

The box of goods ordered of you came all right, and every thing was entirely satisfactory. The articles ordered were cheap, and good too. I have been buying maple sugar for 25 years past; but never, in all that time, got any pure, in my opinion, until I received yours. It is absolutely pure, and of the best quality. Many thanks for promptness and low prices.

WM. M. KEER.

Salineville, O., Aug. 5, 1887.

THE NOVICE EXTRACTOR.

The goods came on the 24th, in perfect order, freight reasonable. Accept thanks for your excellent manner of packing. The extractor is the first "Novice" I ever saw; and I must say I like it much better than I expected to—in fact, I could not be better pleased with one. I gave the solar wax-extractor a trial yesterday and found it satisfactory for extracting wax. I see by the wrapper on GLEANINGS my subscription has expired; as I can not think of doing without it, send it on another year.

MISS A. M. TAYLOR.

Mulberry Grove, Ill., June 28, 1887.

THE BEE-KEEPER'S HAT.

My buckwheat came sooner than I expected. I have it sown, and now it is raining almost a deluge. My clover seed is all right; and the hat—well, I don't see how any bee-keeper can afford to do without one when the cost is so trifling. I fear I shall have to get me another, as my girls have captured mine already.

THOMAS HORN.

As to the Thomas Horn business, I consider you an honest man. You put the advertisement in your paper for us to read, and I and many others thought we might make a good thing out of nothing. We were all more dishonest than you, for we wanted something without paying for it. I don't think I would pay a red cent to any one of his dupes, as you put the adv't in as all other periodicals do, thinking he was honest.

W. K. JAMES.

Loudon, Tenn., Aug. 4, 1887.

CONVENTION NOTICES.

The Southwestern Iowa Bee-keepers' Society will hold its next annual meeting at Emerson, Mills Co., Ia., on Thursday, Sept. 1, 1887. All interested are invited. E. W. FITZER, Sec.
Hillsdale, Ia.

When thou passest through the waters, I will be with thee; and through the rivers, they shall not overflow thee. ISA. 43:2.

SENDING IN ORDERS FOR GOODS WANTED NEXT SEASON.

WITH the poor honey crop that has been secured in most localities, we presume it will not be a very great inducement to make purchases so long ahead. Where one has money, however, that he has no particular use for, quite a saving may be made by purchasing in the fall, especially where you have decided as to what goods you expect to use, so there is almost no possibility but that they will be wanted. It is also very convenient to have the goods on hand all ready for use long before they are needed; and it is such a convenience to us to fill orders during these months of comparative leisure, we have decided to make the large discount on orders received during the month of September, as given in the next column.

THE AUSTRALASIAN BEE-JOURNAL.

JUST as we go to press, Vol. I. No. 1 of the *Australasian Bee-Journal* comes to hand. It is edited by I. Hopkins, and published by Hopkins, Hayr & Co., at Auckland, N. Z. It is well printed on good paper, and altogether in make-up and general arrangement it presents quite a creditable appearance. Mr. Hopkins was the editor of a former journal, entitled the *New Zealand and Australian Bee Journal*, which, after two years of existence, died for want of patronage (but not, we believe, from the lack of editorial talent). Since this time the progress of apiculture has so far advanced in Australia and the neighboring islands that the present management feel warranted in starting another journal.

GETTING A GOOD YIELD DURING SEASONS THAT OTHERS GET LITTLE OR NONE.

WE have two bee-keepers in Medina County who have secured quite nice crops of beautiful comb honey. One is W. H. Shane, of Chatham Center, and the other is M. G. Chase, of Whittlesey. Both of them use 1½-inch sections — the kind that D. A. Jones sends out as his regular-width sections. The honey is the nicest we ever handled. Mr. Shane has this season secured about 6000 lbs.; and, strangest of all, he has always had a crop of fine honey ever since he commenced keeping bees, and he keeps this up right along, even when bee-keepers north, south, east, and west, universally say there is no honey at all. It is just so in market-gardening. Give us a man with sufficient energy and enterprise, and he will have a crop, no matter what the season may be. We have just paid 16 cts. for over half a ton of the above honey.

SPECIAL NOTICES.

DISCOUNT ON GOODS BOUGHT THIS FALL FOR NEXT SEASON'S USE.

AFTER Sept. 1, until further notice we will give a discount of ten per cent on goods strictly for next season's use, except the following: Machinery of all kinds for manufacturing; all tin and glass honey-receptacles; tin plate; all counter goods. On Simplicity, portico, and chaff hives, we can give only five per cent. The principal goods included under the 10% discount are foundation, frames, sections, zinc, extractors, comb-foundation machines.

A FOUR-COLOR LABEL FOR ONLY 75 CTS. PER THOUSAND.

Just think of it! we can furnish you a very neat four-color label, with your name and address, with the choice of having either "comb" or "extracted" before the word "honey," for only 75 cts. per thousand; 50 cts. per 500, or 30 cts. for 250, postpaid. The size of the label is 2½ x 1 inch—just right to go round the neck of a bottle, to put on a section, or to adorn the front of a honey-tumbler. Send for our special label catalogue for samples of this and many other pretty designs in label work.

EXTRACTED CLOVER HONEY WANTED.

SINCE our last we have sold out entirely our stock of extracted clover honey, and shall have no more to offer till we succeed in getting some more. We shall be pleased to receive samples (with your name and address plainly marked on them), and the price you will sell for of either this or last year's crop, clover or basswood extracted honey. If you have not any thing to send a sample in, remember we will mail you, free, a small vial in a wooden block, in which to send us a sample. Remember, too, that we will pay more for honey in our 60-lb. square shipping-cans than in any other package. We want only first-class honey.

LATER.

WE have just sold the last of our stock of extracted basswood honey, and can fill no more orders till we get another lot. We have one case of 2 cans of raspberry honey at 7c per lb. We have also 12 five-gallon iron-jacket cans of a poorer quality of fall honey, 50 lbs. to the can, that we offer at 6 cts., can included. The can is worth 50 cents.

WHITE COMB HONEY.

WE have closed out our entire stock of old comb honey, including the large lot of glassed honey we have mentioned several times. We have, however, secured some of the nicest white comb honey of this year's crop that we ever handled. It is in sections 1½ wide, averaging about ¾ lb. each, 28 sections in a single-tier case. This honey is so nice that we shall have to get 18 cts. per lb. in case lot, case included.

ASH KEGS FOR EXTRACTED HONEY.

FOR SALE--A FARM IN TENNESSEE

A 90-acre farm, 14 miles from Nashville; heavily timbered, 50 acres with a new rail fence, about 15 acres clear, half of this in a young flourishing orchard; ¼ of an acre in grapes. Plenty of room for a large family; a good stable for about 15 head of cattle, good ice-cold spring water, shop with a water-wheel suitable for hive-making, or to turn a corn-mill, with farm implements, 50 Italian bee swarms in Langstroth hives, 18 head of cattle; horse and wagon; a French-buhr mill, and a common thrasher, on the place, to be run by water power. All for \$2500. A very good place for a man to start a saw-mill, by steam or water power. For particulars, address

HONEY COLUMN.

CITY MARKETS.

CINCINNATI.—*Honey.*—The demand from manufacturers is very good of late for extracted Southern honey, and fair for clover honey in small packages for table use. Our stock of Southern honey has been reduced considerably, and we shall be in the market again this fall. There were few arrivals lately, and prices may be quoted at 3@7c on arrival, according to quality.

Comb honey has been sold out, perhaps better than ever before at this time of year. Only remnants of dark honey are left over. Choice white comb honey would bring readily 15c in the jobbing way. No arrivals of new comb honey have reached our city yet, that we know of.

Beeswax is in fair demand, and brings 20@22c for good to choice yellow on arrival.

Aug. 19. CHAS. F. MUTH & SON,
S. E. Cor. Freeman and Central Ave's.,
Cincinnati, Ohio.

St. LOUIS.—*Honey.*—We quote choice comb 10@12 cts.; latter is for choice white clover in good condition. Strained, in bbls., 4@4½ cts. Extra fancy, of bright color and in No. 1 packages, ¼ cent advance on above. Extracted, in bbls., 4½@5½ cts.; in cans, 5½@6 cts.

Beeswax, 21 cts. for prime.

Market very firm at above prices. Owing to the short crops reported everywhere, we look for a still further advance in prices.

Aug. 25. D. G. TUTT & Co.,
206 N. Commercial St., St. Louis, Mo.

NEW YORK.—*Honey.*—Our market is opening up earlier than usual, and at higher prices. We quote as follows, until further notice:

Fancy white, 1-lb. sections, 16@18; same in 2-lb. sections, 13@14; fair to good, 1-lb. sections, 13@15; same in 2-lb. sections, 10@12. White-clover extracted, in kegs or barrels, 7@8. *Beeswax*, 21@22.

Aug. 24. MCCAUL & HILDRETH BROS.,
28 and 30 West Broadway, New York City.

COLUMBUS.—*Honey.*—Our market is no better off than last reported. We can't hear of any, scarcely, and no one will put a price. We are having a number of calls, but no honey to fill orders. We are still in hopes that we shall be able to get honey from some locality. There can be no price put upon it, as we can't guess the extent of the scarcity. So far there is none to get here.

Aug. 23. E. CLICKENGER & Co.,
Columbus, Ohio.

KANSAS CITY.—*Honey.*—White comb, 1-lb. sections, 16@18c; dark, 15@16c; white, 2 lbs., 15@17c; dark, 2 lbs., 14@15c; California, white, 1 lb., 15@17c; dark, 1 lb., 14@15c; white, 2 lbs., 15@16c; dark, 2 lbs., 14c; California extracted, white, 7@7½c; dark, 6@6½c. No white-clover extracted in market.

Beeswax.—No. 1, 20@22c; No. 2, 16@18c.

Aug. 24. CLEMONS, CLOON & Co.,
Cor. 4th & Walnut Sts., Kansas City, Mo.

MILWAUKEE.—*Honey.*—This market is in good condition to receive shipments of honey—comb honey wanted. New 1-lb. sections, white, 16@17; same, in 2 lbs., 14@15. New extracted, in barrels, 7@7½; same in kegs, 7½@8. New extracted, in kegs, dark, 6@6½. We would advise shipments.

Beeswax, 25c. A. V. BISHOP,
Aug. 22. Milwaukee, Wis.

CLEVELAND.—*Honey.*—The market is in excellent condition; all receipts to date have been promptly sold at 16c for best 1-lb. white unglassed, and there is now every indication of a slight advance; 2-lbs. would sell at about 2c less. Choice white extracted is wanted at 7@8. *Beeswax*, 25. A. C. KENDEL,
Aug. 23. 115 Ontario St., Cleveland, Ohio.

KANSAS CITY.—*Honey.*—Choice white 2-lb. sections, 15c; dark, 2 lbs., 12@13c; choice white 1-lb. sections, 18c; dark, 1 lb., 14@14c; California, 2 lbs., 13@15c. Extracted, choice white, 8@10c; dark, 5@6c; California white, 8c; amber, 6@7c. *Beeswax*, 20@22c.

Aug. 25. HAMBLIN & BEARSS,
514 Walnut St., Kansas City, Mo.

St. LOUIS.—*Honey.*—There is a little better feeling in the honey market. From our information, crop will be short fully one-third from last year's crop, and in some districts almost entire failure. Choice white-clover comb honey, 1-lb. sections, 12@13c; fair, 10@11c. New white clover, extracted, in cans, 7@8c; bbls., 5@6c. Southern honey, bbls., choice, 4½@5c; fair, 3½@4c; baker's, 3@3½. *Beeswax*, steady, 21c. We look for good active demand for honey this fall.

W. B. WESTCOTT & Co.,
Aug. 25. 103 & 110 Market St., St. Louis, Mo.

CHICAGO.—*Honey.*—Honey is in brisk demand in a small way at 17@18c per pound for white 1-lb. sections. Extracted is also active at 6@7c for white. There is very little comb or extracted honey on this market. *Beeswax*, 22@24c.

R. A. BURNETT,
Aug. 23. 161 So. Water St., Chicago, Ill.

NEW YORK.—*Honey.*—The market is entirely bare of old honey. We expect new honey about the first of the month. The price will range, for white clover, from 13@15c. Do. 2-lb., 10@12c.

Aug. 24. THURBER, WHYLAND & Co.,
New York City.

DETROIT.—*Honey.*—New comb honey is very scarce, and quoted at 16@18 for best white comb in 1-lb. sections. Extracted, 10@12c.

Beeswax, 25c. M. H. HUNT,
Aug. 10. Bell Branch, Mich.

BOSTON.—*Honey.*—Present indications point to a very short crop of honey, and present prices for new honey are from 20@22c for 1-lb. sections, and 18@20c for 2 lbs.

BLAKE & RIPLEY,
Aug. 25. 57 Chatham St., Boston, Mass.

WANTED.—I should like to buy 100, 200, or 300 lbs. of extracted honey, if I can get it cheap enough. I should like clover honey.

Mrs. M. A. WILKINS, Seneca, Nemaha Co., Kan.

WANTED.—To purchase from one to five thousand pounds choice white-clover honey in one-pound sections. Crates to average about 25 lbs. each.

I. T. CARSON & Co.,
15-16d 325 West Main St., Louisville, Ky.

A CARD.

Having resigned my position with Thurber, Whyland & Co., I beg to inform you that I have assumed the management of the honey, maple sugar, and wax department of the well-known house of F. G. Strohmeier & Co., New York. I feel assured that, with their facilities, I can meet your wants in the above line. Thanking you for past favors, and asking for the future your kind consideration, I remain yours very truly,

H. SEGELKEN.

TO BEE-KEEPERS.

In the interest of the bee keeping public, as well as in order to increase business, we wish to make generally known that we deal especially in honey and beeswax. Our personal acquaintance with the trade all through this country, and our connections in foreign markets, enable us to handle any quantity of comb and extracted honey and wax most advantageously. It is our aim, not only to supply the demand, but also to create demand, especially in those parts of the country which heretofore have been overlooked or neglected. Honey at present prices ought to be used as a regular food-product by all classes. It is to the interest of every thoughtful apiarist to increase the consumption in order to equalize the rapidly increasing production, and thus to uphold prices. But it is also absolutely necessary to offer to consumers the pure and perfect article only, in order to maintain their confidence. With the co-operation of the bee-keepers, we can attain our object. We solicit correspondence and consignments. On the latter, cash will be advanced. Prompt returns guaranteed.

F. G. STROHMEYER & Co.,
122 Water St., New York, August, 1887.

Referring to the foregoing circular we beg to call your attention to the fact that we are the only house in the United States making a specialty of the following articles:

Comb and extracted honey; maple sugar and maple syrup; beeswax; Brazil (or Carnauba) wax; Japan wax; African wax; paraffine; ceresin; ozokerite; stearic acid; bitumen; laundry wax. Thus offering a complete line of goods, we guarantee the same to be always of best and carefully selected quality, all of them bearing our trademark.

F. G. S. & Co.

If you Wish to Obtain the
Highest Price for Honey

THE BEST FOUNDATION.

DR. MILLER TELLS US WHY HE HAS GIVEN UP THE GIVEN FOUNDATION, ETC.

I USED Given foundation, and liked it better than any thing I had previously used. Perhaps there was some prejudice about it, and I don't know that I could have proved it was better; but the bees took hold of it nicely, and the wax in it seemed stronger than in other kinds of foundation—at least, the side walls did. But as you say, friend Root, I have given up Given, and for the same reason, probably, that others have—simply because it's not on the market. You never offered it for sale, and I'm not sure that anybody did; and if it had been on the market, I think I should never have given up using it—at least, not till last spring. If I remember rightly, the Dadants refused to make it, because they couldn't succeed in making a nice article, and perhaps that's the reason you and others don't make it. I don't think I ever saw Given foundation as uniform in thickness as that made on a mill; but in spite of that, if it had been as readily obtained I should have taken it in preference to any other up to the time I was in Medina last spring.

One day while I was sitting in Ernest's corner talking, Mr. Calvert came in with a long strip of foundation, and said, with a smile beaming all over his pleasant face, "We've made a discovery;" and then he showed us the foundation. Judging from its looks alone I should prefer it to the Given, and I got a lot of it; but owing to the failure of the season it has never been used.

COMMON SENSE IN DOCTORING.

I am heartily glad, friend Root, that your wife, or somebody else, is bringing you to your senses.

Perhaps you remember how I urged with all my might that the lounge was the medicine you needed; and I think *sometimes* you rested yourself when exhausted, by rushing about outdoors just about in the same way that a drink of whisky would have rested you.

But I can hardly see how the tired housewives are to follow your advice to rest before dinner. In most cases (ask your wife if I am not right) the attention of the wife and mother is urgently needed in getting the meal ready up to the time of sitting down to the table, and we hardly want to eat without the presence of the mother at the table; so where is the chance for the nap before dinner? But an after-dinner rest can be taken; and upon this the husbands, sons, and daughters should insist. I know an old lady who takes a snooze every day after dinner, sitting in her chair, and her daughter worries that there is just so much delay in getting the work done up. It is not unkindness, but ignorance, on the part of the daughter; for if she understood that that snooze is just lengthening so much the life of a fondly loved mother, the old lady would find herself forcibly taken and laid upon a bed for a more comfortable nap; and we be to the one who should wake her! Two of the prevailing feminine sins are making up a bed as soon as it is vacated in the morning, and rushing at the work as soon as dinner is over.

KEEPING QUEENS OUT OF SECTIONS.

I wish I knew the place to which friend Howell, on page 623, refers. I don't remember distinctly about it, but this much I know: That very rarely does a queen trouble the sections (so rarely that it's hardly worth considering), and there is no secret about it. I am not sure that I have any thing to do with the matter. The slat honey-board, I suppose,

is something of an obstacle; the presence of separators may help, although I have no trouble without separators, and the distance of the sections from center to center (about two inches) also helps. Still, I have not had trouble, even with 1½-inch sections. Some say the queen goes up to lay drone eggs because there is no drone comb below. I have generally no drone comb below, but then the sections are filled with worker foundation. So in my case, the conditions are, the slat honey-board, separators, and two-inch sections filled with worker foundation. I suspect that the essentials are the honey-board and full-sized starters. Possibly if the brood-chamber is too much contracted, the queen might be forced up.

THE BEE-KEEPER'S HAT.

I have worn one nearly all summer, and I like it better than the five-cent hat, which is high praise. The women-folks prefer the five-cent hat because of its more drooping habit, thus making them less sunburnt; but I don't think there is any thing wicked in being sunburnt.

GETTING A GOOD CROP IN ANY SEASON.

There you go again, friend Root, riling me by your remark on page 637: "Give us a man with sufficient energy and enterprise, and he will have a crop, no matter what the season may be." Now, I had this spring the best lot of bees I ever had, and never worked harder to have every thing in good shape, and never had less to reproach myself with as to my own management, but I have no crop. Colonies that were strong and in good condition in the spring, and have continued so right along, have gained not a pound; and when I open them, the vacant, uncapped cells at the top of the brood-combs stare me in the face. Now, will you tell us the management or "energy and enterprise" that would secure a crop in such a case? Heretofore my lack of energy may have been at fault; but with the present season of drought I plead "not guilty."

C. C. MILLER.

Marengo, Ill.

Look here, old friend! aren't you a little cool about taking the position you do, that tired housewives can *not* doctor without medicine, as I have been recommending? Imagine the husband or a child saying to the mother of the household, "Dear mother, we are well aware that your life would probably be spared to us fully ten years longer if you could take a short nap just before dinner: but the way we are situated, I think you will have to do the best you can; and when you die we shall have to get somebody else to take your place. We can not possibly spare you to take your nap, the way things are now; but may be you might get some quinine, or some sort of bitters, of the doctor, that would strengthen you up a little. It is quite likely that it will not enable you to live any longer in the end, but you see it is quite impossible that we should spare you for even twenty minutes, just before dinner time." I want every husband, every son, and every daughter, to read the above and ponder on it. Has it not some sort of application to the state of affairs in your household? — I declare, friend M., I entirely forgot all about you when I made my sweeping assertion. If I should take it back now, you would all say I did it out of respect to present company, and then the rest would all

laugh, and the matter would be worse off than if I let it alone. Why, is it indeed true you did not get any honey at all in any one of your apiaries? I will tell you what the trouble is: You have too many colonies in one location. Dr. Mason, you know, recommends only ten in one place; or, at least, if he did not say that, it was something to that effect. Now, may be if you try again with a small number of colonies in a good locality you will conclude I was pretty nearly right, after all.

GIVEN FOUNDATION.

THE REASON WHY FRIEND HEDDON HAS GIVEN IT UP.

ON page 610, in your foot-notes to friend Hutchinson's article, you call upon me to state what may be my present idea of Given comb foundation, and why I do not handle it now, and why I have changed my mind, etc. How simple, seemingly, complex problems appear, when fully understood! After all I have written and said in favor of the Given press, had I changed my mind, after more experience, it would have been a duty to have publicly stated the change, and the reasons for it, and a duty which I should have promptly and pleasurably fulfilled. Now, if you will look over my writings you will find that, while I have always given a decided preference for the press, as a means of making wax into foundation, I have given the foundation only a little preference, at the same time saying that the best rolled foundation was good enough for any one. The difference is slight, but it has always been, with us, in favor of the Given foundation.

I have worked no less than seven roller mills, of four different makes, and nearly as many different Given presses, and to-day I would use no other machine than the Given press. My preference for it, for speed, ease of operation, etc., is radical. Now, why don't I use it? Why, because I don't use *any*. Well, why don't I deal in Given foundation? Because I can't buy it in large quantities at wholesale rates. I tried to do so, before I adopted the Dadant foundation. No one makes it to wholesale, in sufficiently large quantities to supply me. Some one might agree to, but fail. I can't fill orders with promises. I preferred to become one of Dadant's jobbers. I will tell you why.

1. They make a most excellent article of rolled foundation. It is made upon honor and judgment.

2. They are almost specialists (please remember that I always plead for specialty), and that greatly aids the fact that their work is nearly perfection, and that they are always ready to fill orders promptly.

3. These men are so honest and fair in deal, that no energy need be expended in watching and weighing after them. They seem to have found out that honesty is truly the best business policy, and they appear to feel that there is no pleasure to the heart in injustice. They seem to recognize the fact that virtue is its own reward. I can't agree with many of their mechanical deductions, but I do most heartily indorse their integrity, and their consistency in its adoption and use. In this special sphere, I hold this firm as worthy of the position of a guiding star to our fraternity.

I used to think, and it was nearer true then than

now, that the ownership of from 40 to 50 colonies of bees warranted the purchase and use of a comb-foundation machine; but since the many improvements in its manufacture, I have found that such is not the case. You are very well aware, that not only special skill is required, but special room and fixtures, and plenty of it; and although I now have between five and six hundred colonies, and use foundation in full sheets everywhere, and sell about ten times as much as I use, I prefer to purchase rather than to make my foundation, devoting more time and energy to other departments. When I look at the extremely low prices of your counter goods, I do not forget that specialty in manufacture has done much to aid inventive genius in so cheaply supplying us. JAMES HEDDON.

Dowagiac, Mich., Aug. 22, 1887.

Friend H., you have given Dadant & Son a pretty big puff; but I am glad to see it, because I think they are deserving. In regard to buying foundation instead of making it for forty or fifty colonies, if I am right it depends a good deal on how much spare time the owner has. Where he has not as many irons in the fire as you and I have, friend Heddon, but, on the contrary, has spare time, especially in the fall and winter, he can make very good wages indeed in making his own foundation, and supplying his neighbors for several miles around, even if he does not make a business of furnishing supplies and shipping to order. Since you speak of it, I believe I have never heard any one say that he ever sent an order for foundation to the Dadants, and it was neglected or delayed.

PREPARING FOR WINTER.

FRIEND DOOLITTLE TELLS US HOW TO DO IT AND WHEN TO DO IT.

THAT prince among bee-keepers of twenty years ago, Elisha Gallup, once wrote that August and September were the months in which to prepare bees for winter; and after the experience of last fall and winter (which winter was the worst season for bees ever known in this locality, they being confined to their hives on the summer stands for five months without flight), I am ready to agree with Gallup exactly. A year ago I commenced getting the bees ready in August, finishing in September, and I never had bees winter as well during a severe winter in all of my 18 years of experience. As I am again getting ready for next winter, I thought perhaps some of the readers of GLEANINGS would like to know how I did it. By beginning at this date to put all in readiness as far as possible, I give the bees a chance to get their stores for winter placed just where they wish them, so that, by the middle of October, they are ready to go into that quiescent state so conducive to the best results. Working along this line, I proceed as follows:

I go to each hive, open it, and carefully remove each comb, noting the amount of bees, age of queen, square inches of brood, and pounds of honey. The pounds of honey are found by weighing a few combs of varying fullness till the eye gets so trained that every comb can be counted off as to weight of honey with an accuracy approaching

perfection, while the square inches of brood is gotten by measuring a few different-sized patches, when it is easy to estimate it afterward. The age of the queen is told by looking at the last year's record, if her wings are clipped; if not clipped, I know she is of the present year's rearing, as the wings of all my queens are clipped in fruit-bloom, and the amount of bees is told by observing their appearance on the combs. When I go over the hives in this way, I have some pieces of sections so that, as soon as a hive is closed, I can write down all about the condition of the inside. The piece of section may read something like this: "Aug. 20, 1887; 20 lbs. honey; 450 sq. inch. brood. Bees, plenty, with good Italian queen, reared in '85."

This piece is now laid on top of the honey-board or quilt to the hive, and the cover put on, when two little flat stones are put on the cap to tell me that, inside said hive, they are short of honey, but have brood to spare. For instance, if the stone is at the front right-hand corner, it says, short of honey; if at the left back corner, it says, brood to spare; if at the right back corner, it says, honey to spare; and if at the left front corner, it says, short of bees and brood; while, if all is as I wish it for winter, a stone is placed in the center of the cover. In this way I make these little stones tell me, at a glance over the apiary, just what each hive contains, so that it is now but a few minutes' work to go over the yard and equalize all so that each is in a similar condition for winter, when the little stones are taken off and slipped under the bottom-board of the hive, where they belong when not in use. If any are still short of stores (25 lbs. is what I allow each colony) after equalizing, I feed to make up the deficiency, generally using honey, as I prefer it to sugar stores after repeated trials. As I write this out it looks like a long tedious job, and the readers of GLEANINGS will doubtless say that, rather than go through all this operation, they will simply lift the hives as heretofore and "guess" that all have enough to carry them through. But to handle three or four hives is to become an expert; and if the readers will only try it they will soon find that, after a little, they can count off honey, brood, and bees, as fast as they can handle frames, which, together with the satisfaction of knowing just what each hive contains, will never allow them to go back to the "lifting-guessing" plan again.

Then I have also learned a new plan of uniting nuclei or queen-rearing colonies for winter, so that they can be ready early instead of being only poorly fixed at best when left till October, as they usually are. It is this:

The latter part of August, select the strongest ones from the lot, or as many as you desire to winter, and go to the others and take all but a little brood away from them, dividing said brood among those selected for winter. In doing this I take all the bees along (less the queen) that adhere to their frames. These frames of bees and brood are set right in the selected hives, and so far I have not had a single bee or queen killed. The bees hatching from this brood are the ones which go through the winter, and I like uniting in the brood form much better than in the bee form. The bees left in the now small nuclei are used up, and mostly die of old age by the time I am through queen-rearing for the season. G. M. DOOLITTLE.

Borodino, N. Y., Aug. 18, 1887.

I believe, friend D., the substance of the

above has been given us before—possibly some years ago; and it is quite interesting, to me at least, to know that you have made no material change in your manner. Very likely no change is needed, especially if it is successful. I think I should prefer the slates to the pieces of sections and little stones you use. Perhaps the plan is the best one for you, however. Ernest suggests, while I am dictating this, that the stones have an advantage over the slates, inasmuch as they can be seen quite a distance away, and this surely is a valuable point. In case of your sickness or absence, however, it might be a little difficult for a new hand to get the hang of the meaning of the stones placed in different positions. Doesn't a heavy wind tumble them off sometimes?—Your plan of uniting colonies is similar to the one we have used for many years, only I should make the attempt to put, in some colony near by, the old bees which are left, because I felt sorry for them if for no other reason.

OUR P. BENSON LETTER.

P. Benson A. B. S. His Cattlelog & Prize List Kontinude.

HUNNY STRAINERS—\$1.25.

THESE air made of table cloths kairfoolly wore to the rite thickness, soze to strain the hunny throo and leave the dead bees & bee bred in the cloth. This is less than the cost of matecrial, without chargin enny thing for the trubbel of havin them wore down, but thay ar offered at this low prise for a short time to introjuice them.

HUNNY BOXES—5 cts.

Flattened by the 100 - - - - \$5.25.

COBM EXTRACTORS.

Cobm extractors, per pair - - - - \$.50.

These extractors is yused to lift the cobms out of the hive, soze not to git stung. By taking it at nite, when the bees kant see to fly, the most timid ken extrack the cobms out of the hive without a sting.

TIN PANS FOR SWARMING—\$.50.

These pans is constructked ackordin to the latest improvements of modern sighthens, with thair acowstick properties intensyfyde & condenst, soze to maik a moast outrajis nois whareby the bees is injuiced to lite moar promp than enny other nois.

3-PLY BEE-MITTENS—\$1.30.

These mittens has never bin noan to fale. Thay ar made of three thickness of sheepswool, & giv curridge to the opperrater so be ken go at the bees with undanted bravery.

RESEAT FOR HUNNY—\$2.00.

This reseat ken maik the finest hunny out of harmless materials to be found in evry fammaly, sitch as shooger, wotter, glew, starch, & so forth. The ingredieneces doant cost to eckseed 5 sents a pound, makin the prophet grate. If this is soled at (25) twenty-five sents its a clean prophet of 20 sents. You ken eezy maik 200 pounds in a day besides dooin the chores, and this wood be forty (\$40) dollars a day, or neerly fifteen thousand a yeer. The

exack amount is \$14,600 dollars. As I have onaly a fue of these reseats you better send soon.

WURM ANNIGHHIGHLATER.—\$.75.

Next to the moth miller the wax wurm is the wurst ennemy on the subject to the bee. When a swarm is took up the wax wurm gits into the cobms and eats them up, and it's so hard to find and pick them out that I have devised a implement entitled the wurm annighhIGHLATER whitch is automatic in its axion, and gits out the last wurm.

P. BENSON'S WURM ANNIGHHIGHLATER.

DRIED TANZY, PER PACKIDGE.—\$.25.

To rub on hives to maik swarms stay.

Olways send a little more than the prise, to allow for flucktuashen in the market. If enny of my customers is dissatsifde the munny ken be cheerfooly refunded to me.

In riting letters of inquiry, inclose yure real name, not nesserly for publickashen but as a garn-tea of good faith. Also a postidge stamp.

P. BENSON, A. B. S.

ON THE RIGHT PLATFORM.

OUR FRIEND J. M. JENKINS ON THE SUPPLY-BUSINESS.

FRIEND ROOT:—The honey season has proven a failure for surplus with me, but I think the bees will have plenty for winter. We had a drought in April and May, and that is when our best honey is gathered, and it is the main crop. They are doing as well in summer as usual, but they can't make any surplus of it, and it is not much good any way. But "the harvest" with me in the supply-business has been fair, and I am satisfied. I have taken in about \$1500, or about double what I did last year, and I think my prospects for doubling it again next year are good. I am now building an addition to my factory, that I may have more room.

My business here is small and insignificant compared to yours and probably others'; but I feel sure of success after two seasons' experience, and I am willing to put more into it. I have learned how to greatly reduce expenses and thus increase the profits, and the end is not yet. I might also say, that I have made only one enemy that I know of among my customers, and I don't know whether he failed to answer my last letter for shame or anger, and I don't know how he feels now. I always do my best to please, and give satisfaction, and if differences arise (as they surely will) I do any thing, or offer any thing, to satisfy the customer. I am simply trying to follow the teachings of A. I Root, and of Him who said, "Do unto others as you would have others do unto you." I never want any man to feel that he didn't get his money's worth of me, or that I got the best of him in a bargain. I make as prompt shipments as possible; and if I have to delay the shipment more than 24 hours, I explain at

once and let the customer know what to expect. In our inexperience we have a few times left out parts of a shipment, as rabbits, or pieces of frames, and I always forward the same by postage or express paid, and apologize. Friend R., that is the kind of "platform" I am running on. I tell you all this because I am under everlasting obligations to you, and I feel that you have a right to know what I am doing. I might also add, that I decline credit to all alike.

J. M. JENKINS.

Wetumpka, Ala., Aug. 23, 1887.

BEE-KEEPING AS A LIFE BUSINESS.

C. C. MILLER GIVES US SOME EXCELLENT FACTS IN REGARD TO THE MATTER.

"IT seems a pity he should settle down into nothing but a bee-keeper, when he might be successful in almost any line of business he should undertake." Such expressions I have heard, when, so far as I could see, the only reasons for it were that it was thought the man might make more money at some other business than bee-keeping. I am aware that too much has been said of the bright side of bee-keeping in the way of urging every one into it, and I have protested against it; for in nine cases out of ten, the person who chooses bee-keeping as his life business, *merely* for the money there is in it, will meet with disappointment. But for once I want to take the other side, and say something in the way of urging the choice of this business upon a certain class. Here is a young man about to settle down in life. His college course of study is perhaps finished (and I would urge upon every young man to get a collegiate education, whether he expects to spend his life in apiculture, farm, counting-house, or pulpit); and the question is, whether bee-keeping shall be his vocation. He has aptitude for the business; what little experience he has had in it has been successful; and he would really like to spend his life at it if he thought he could make as much money at it as at merchandise, albeit the confinement of a merchant's life is not to his taste. But the matter of money stands first in consideration, and he decides in favor of mercantile life. My young friend, you are making a mistake. In the first place, it is by no means certain that you will be one of the successful merchants. But suppose you are, and that you make double or ten times as much money as you could at bee-keeping. You go on at your business, looking forward to the time when you can retire, and enjoy life. There are events that may hinder the realization of your expectations. You may not live long enough. If you do, you will find that your tastes have somewhat changed, and that the life to which you have for years looked forward with bright expectations is mainly a disappointment. On the other hand, if you follow your inclinations, and adopt the pursuit of a bee-keeper, there is no necessity for looking forward to a certain time in the future for your enjoyment of life. You can take your enjoyment as you go—mixed, it is true, with pain and toil, but still a life of enjoyment. You have one important advantage over the merchant: your outdoor life gives you a physical vigor he can not enjoy. He has poorer food than you, even if he eats from the same dish, for he has not the same hunger to sate

it. The mere fact of existence is a pleasure to a perfectly healthy animal, be he man or beast; and the man who eats his food with a thorough relish is the better man for it, physically, mentally, and perhaps morally and spiritually.

HIGH VERSUS LOW SALARIES.

There is another view that is worth taking, and it applies to all callings—bee-keeping or what not. Compare two positions in life. A man in Chicago has a salary of \$2000, and his brother in a country village has one half as much, \$1000. Which has the better place? Perhaps the Chicago man, perhaps not. Throwing aside all other considerations, and taking just a dollar-and-cent point of view, if the country man's annual expenses are \$600, and those of the city man's \$1700 (and there may be that difference, even when each seems to be living equally well), the result will be that the country man will lay by one-third more annually than the city man, in which case the \$1000 salary will be better than the \$2000. Suppose, however, that the annual expense in the city is \$1500, and \$600 in the country. In this case, \$500 is annually saved out of the \$2000, and \$400 out of the \$1000. Is the salary that clears the \$500 one-fourth better than the salary that clears the \$400? And it is to this particular point I want to call the especial attention of the young. Nine out of ten of the young will be dazzled by the larger salary; and when to this is added the larger annual saving, the question is definitely settled in their mind. If they think far enough ahead they may find a factor they have omitted from the problem. When the time comes to retire from service—it may never come, and it may be forced upon one before he desires it—when this time comes, the city man will be so fixed in his habits and mode of living, his family in their social circle, that he must continue his same life and same expense of living. Even if he had thought of going back to his former country life, he will now find it impracticable; the rule is, that men do not. Now let our two men be compared after the same number of years of service, say 15 years. In that time the one saving \$500 per annum has \$7500 ahead; and the other, saving \$400 per annum, has \$6000 ahead. But what is this worth to each of them? The first, spending \$1500 per year, can live on his \$7500 just 5 years; and the second, spending \$600 per year, can live on his \$6000 just 10 years. So you see, when looked at from this point of view, the \$1000 salary is worth just double as much as the \$2000. In other words, the \$2000 man lays by each year enough to support him 4 months, while the \$1000 lays by enough each year to keep him 8 months. Some of you young men that are itching to get into places to make money faster, think this over. It may make you a little more content where you are. C. C. MILLER.

Marengo, Ill.

Friend M., while reading your excellent suggestions, a text kept all the while running through my mind. This text is one of my particular favorites just now. Even though most of you have heard it perhaps a hundred times, I will repeat it here: "Lay not up for yourselves treasures on earth, etc. Now, I do believe that too many young men choose an occupation from the standpoint of money, just as you put it; and whoever does this will make a failure in one way if not another. I have had considerable experience in mercantile business,

as well as in outdoor work, and I would not give up the privilege of spending half of my time out in the open air, for any salary that could be offered. It is not only the open air with me, but it is the opportunity of meeting face to face God's work, and of enjoying direct his great and wondrous gifts; and I would not stay in a store, from daylight till dark, as I have done year after year in times past, losing the relish for food, as I used to lose it—losing also the keen zest and pleasure that even existence gives—for any salary that could be mentioned. In fact, I hope that the larger the salary that might be offered, the less I should want it.

A VISIT WITH GILHOOLY.

OVERCOATS FOR BEES, ETC.

I WAS just driving past neighbor Gilhooly's apiary, consoling myself with the thought that I was not the only one in the bee-business who had "got left" this year, when out came neighbor Gilhooly himself, in hat and veil, smoker in hand, and a kind of body-guard of cross bees hanging around him.

"Hold on, neighbor Fowls, I want to talk bees with you."

"Whoa! Well, I have no objections if your escort there don't talk back. But what makes you work so early in the morning, when those fellows are so troublesome?"

"Oh! on account of robbers. I'd rather take a few extra stings now, than to be bothered with so many pesky robbers later in the day."

"But you have a tent?"

"Yes, but it's getting full of holes; and besides, a gust of wind would, likely enough, tip it up just at the worst time."

"I see you are working on that row of new swarms—taking off honey, I reckon?"

"Now, neighbor Fowls, that's downright cruel of you to talk like that; but I suppose I'll have to forgive you, as you're in the same boat. Well, I did take off some unfinished sections there, but I am hunting out the poorest queens, to remove them."

"Going to give them new queens, I suppose?"

"No, I'm just going to double them up. You see, they're light, both in stores and bees; and as I've always lost more of the new swarms, I thought I'd make big swarms of them and see if I can't winter new swarms as well as you do."

"Very good, but your old swarms still have the advantage in one respect, and the most important one too, neighbor Gilhooly."

"What's that—in having a young queen?"

"Yes, that is an advantage if she is a better layer; but that wasn't what I was driving at. Your new swarms have new combs, haven't they?"

"Yes, built on foundation."

"Well, those new combs are colder than the old black combs your old swarms have."

"Do you really think there is so much difference?"

"To be sure, I do. See here neighbor Gilhooly, what was your object in sending that poor neighbor that parcel of bedding last winter?"

"Why, to keep him from freezing. You know his old house lets in the cold; but what's this to do with the bees?"

"Just this: A bee-hive lets in the cold too; and to keep them warm you must give them warmer bedding. You must exchange your new combs for old black ones."

"How do you save the brood in the new combs, and keep the queen from laying in them?"

"Why, that's very simple—by using the queen-excluding honey-boards. Take an extra hive, with your old combs in it, contracted just as you want it for winter, put it on the stand, shake the bees and queen in front, then put your combs of brood in the top story, with queen-excluder between, and leave them three weeks."

"But I can't see that the bees will have their bedding, as you call it, around them—only a few will be crowded in the cells; the rest will be clustered between the combs."

"Where they have eaten out the honey there will be at least half of them encased in a warm overcoat."

"How do you make that out?"

"Why, calling the cells half an inch deep, that would make an inch of empty cells; allowing one-fourth for the aforesaid overcoat, that would be equal to three-fourths of an inch, and you wouldn't have more room than that between the combs."

"Well, your warm overcoats won't help those fellows between the combs much—they'll be in their shirt-sleeves."

"True; but they will keep warm with the warmth of their fellows. Just imagine a crowd of thousands of men, half in overcoats and half in shirt-sleeves, crowded together hundreds deep in all directions, all pressing toward the center."

"Yes, just to get a sight of Her Majesty, the queen."

"Correct; like the English, you know, when every Englishman wanted to see the Queen at her jubilee. Well, I must go on. Get up, Jenny!"

Oberlin, Ohio, Aug. 23, 1887. CHALON FOWLS.

Thanks, friend F. We have enjoyed the account of your visit with Mr. Gilhooly. In regard to old combs versus newly built combs for winter, we have this to say: Last winter we wintered 40 colonies on combs which had just been drawn out on foundation. By far the larger part of these combs had never had any brood in them, and yet every one of the 40 colonies wintered perfectly. I know it is generally considered that old tough combs are preferable; but are we perfectly sure of it? It is true, the old combs are filled with cocoons, and theoretically they would make the combs warmer for the bees. Although you do not say so, yet I suppose that these cocoons are in reality what you call "overcoats;" but do these little overcoats make a very perceptible difference in the way in which bees pass the winter? We should be glad to hear from others.

I think I shall have to correct Ernest a little, in his remarks above. Years ago, when we were more intent on increase than on getting honey, or even rearing queens for sale, we used to have much more trouble in getting colonies through the spring, where they had newly built combs, than with old tough black combs; and I believe it is generally conceded that the old black combs are far the best for the brood-nest for winter.

SWARMING AND SWARM-CATCHERS.

VALUABLE SUGGESTIONS FROM W. F. CLARKE.

FOR one, I have settled down to the belief that swarming is to be accepted as one of the unchangeable conditions of bee-life. In common with many others, I hailed the plan of division sometimes called "artificial swarming," and practiced it long enough to become convinced that it was indeed artificial and abnormal. I never had a stock of bees that was thus started on an independent career, whose energy, industry, and efficiency would begin to compare with those qualities as displayed by a natural swarm. I have also tried clipping the queen's wing, and abandoned it for several reasons. First and foremost, it is a fraud on the bees. Nature is constructed on honest principles, and I believe that even a stock of bees resents deception and imposture. They start for that grand gala-time which Nature provides them once a year; and instead of having a holiday excursion they are obliged to turn back in dire confusion and disappointment. It is their annual celebration of independence; and man, by wicked artifices, prevents their enjoyment of it. They feel and act as if balked, which they are, and no mistake. Again, dissatisfaction springs up in the hive. They become disloyal toward their queen. They don't want a leader who can't lead. Something is the matter with the queen. They cabal, scheme, and finally conclude to supersede the reigning monarch. I have no doubt many of our queen-troubles have arisen from clipping and otherwise disturbing the queen. Furthermore, it is very difficult for me

gone outside my own lot of about an acre in extent, to find a clustering-place, except once.

When things are handy for cutting off the bough on which the cluster hangs, that is a nice way of getting possession of your swarm. But it has its objections. A properly trimmed Norway spruce is disfigured by the removal of an important bough, and the symmetry of an apple-tree is spoiled by cutting off here and there a large branch. It is remarkable what a tendency there is in swarms to pick out certain trees, and they soon get cut out of all shape by sawing off limbs. Besides this, it is not easy to saw off a limb without jarring it; and sometimes at the critical moment of separation between bough and trunk there is a serious jar, and, lo! half the cluster parts company with the rest; or the whole swarm becomes disorganized, and, quick as wink, is "over the woods and far away." If you get your bough and cluster safely to the new hive, you are not beyond the reach of mishap. The queen may rise in the air again instead of going into the hive, and then it is "love's labor lost."

Various devices have been suggested for taking swarms, most of which I have tried and found wanting in some particular or other. I can not discuss them in detail here, for I find that this article is getting lengthy, and the special object of it is not yet reached. I want to describe and illustrate a very simple method of taking swarms, which I have evolved during the season just passed, and found more satisfactory than any other with which I have experimented. The idea of it was evolved from an apparatus figured in the A B C of Bee Culture, page 236, as follows:

FIG. 1. A SWARM-CATCHER.

to handle a queen without hurting her. I have not that delicacy of touch, nor that control of my nerves, which is necessary for handling such soft-bodied little creatures. I think real injury often done to queens in the process of clipping impairs their efficiency, and leads to their being superseded. I forbear discussing other preventives of swarming, lest this article should become too long.

Taking it for granted that we are going to let our bees swarm within due limits, we ought to arrange accordingly. First, we want a spacious bee-yard, or, rather, bee-garden, for I don't believe in a bee-yard, like a door-yard, devoid of trees and shrubbery. An apiary should be located on a roomy lot, and be environed by evergreens and low-growing deciduous trees. My experience has been, that bees prefer Norway spruces and apple-trees to all others, for clustering on. In my lot they have had a choice of maples, willows, mountain-ash, chestnut, plum, cherry, pear, and various other trees, together with lilac, syringas, and other shrubs, also pines, balsams, and other evergreens; and in over twenty years they have invariably chosen Norway spruces or apple-trees to cluster on. I may add, that in all that time they have never

The drawback to this device is its being horizontal. You must climb a ladder, get even with the cluster, and in such a free position that you can readily operate the handle; for unless, as described in the A B C, you instantly twist the bag so as to confine the bees, a large portion of them will get away, and, in all probability, along with them you will lose the queen. This drawback is obviated by the use of a wooden handle, as shown in Fig. 2. The construction of the swarm-catcher is also shown, together with the manner in which it is shoved under the swarm. The rod is made in joints, the two lower joints being of stout bamboo, and the upper one of tough ash. Fig. 2 shows the device with the lower joint removed, and which I have so far found quite long enough for such swarms as I have taken with it. As soon as the swarm has dropped into the bag, slant the rod a little, give it one twist, and the bees are all your prisoners. Not a solitary one of them can escape, and the bag lies against the rod snug and secure (see Fig. 3), to await your convenience. If the hive is not quite ready for the reception of the bees they can wait a little while. The bag being made of cheese-cloth, or some such porous material, they

will not smother. When all is ready, their infallible entrance into the hive may be secured by the hoop of the bag being so placed that the bees must escape into the hive or not at all.

FIG. 2. W. F. CLARKE'S SWARMING-DEVICE.

The superiority of this plan over all swarming-boxes, even those with a frame of comb in them, lies in this—that you are not dependent on the will of the bees whether they enter or not. Bees are freaky little creatures. You poke a box among them as the cluster is forming; and if they do not take a notion to enter, you must secure them in some other way. Or if you are too persistent in obtruding your box upon them they abscond, and so get rid of the annoyance. Or, again, you coax them into your box, and then lose them at the entrance of the hive.

I have tried the method—I do not know whose it is, but I first saw it practiced at Mr. Heddon's—of shaking the cluster into a light box or large tin pan, and instantly covering the bees with a muslin or linen cloth. It is better than some of the modes practiced, but not wholly satisfactory to me. You can not always get a good fair shake; and if you do, perhaps fail in getting the cover on properly, or after it is on it is brushed aside while you are climbing down from the tree; and, lastly, perhaps there is a miss in getting the queen out of the box or pan into the hive.

It will, perhaps, be said that my device will answer very well where the cluster hangs in a nice convenient shape as in the pictures; but when it

gets among small limbs of trees, and in awkward places, it will not work. To which I reply, that apple-trees with properly trimmed open heads, and Norway spruces with symmetrical branches, offer

FIG. 3. MANNER OF CONFINING THE BEES.

no chance for the tangling-up of swarms we sometimes witness. There will be here and there an exceptional case; but an apiary having a right environment, such as described at the outset of this article, will give off swarms that will cluster in a ship-shape form, nearly every time. If we surround our bees with high trees, or thickety trees, or plant the apiary where there are no trees at all, we must, of course, take the consequences. Swarms like, above all things, to cluster on trees; and if we provide such as are convenient for ourselves as well as them, they will use them, so reducing our trouble and risk of loss to the minimum point.

WM. F. CLARKE.

Guelph, Ont., Can., July 26, 1887.

Many thanks, old friend, for having given so much prominence to our swarm-catcher, with your improvements. Perhaps I should remark, that the implement, as we represent it in the A B C book, was invented and used by one of our girls who assisted in the apiary, and who afterward for several years managed quite an apiary herself. I believe she used the implement very much as you suggest. The rim around the bag was made of wire. This wire was so springy that, when held upright, it would tip over by the weight of the bag in pretty nearly a horizontal position. She always insisted that it was much more convenient than our swarming-box. I believe a good many, however, rather prefer to *lead* bees than to *drive* them; and my experience with bees shut up in a bag has not been satisfactory. They always behave as if there were a good deal of protest about the whole proceeding; whereas in a swarming-box, or a half-bushel basket, which I like about as well, they behave as though they were acting according to their own pleasure, and I rather prefer to manage bees in that way when it can be done. I have often, however, had second and third swarms when I fairly ached to get them in-

side of a bag, or in some other place where I could make them stay and behave according to *my* notions instead of theirs.—I want to congratulate you, friend C., on the picture you sketched, of a fine old gentleman—farmer or bee-keeper. Just to look at his placid face and deliberate (I was going to say movements) position, is an encouragement. When you feel inclined, please give us some more from real life, along with your writings, and we extend the same invitation to the rest of our readers.

MRS. CHADDOCK'S LETTER.

HER EXPERIENCE AT A CAMP-MEETING DURING DRY WEATHER.

BEES have done nothing this summer—have not gathered enough honey to winter on—will have to be fed, or starve to death. We have not had a good old-fashioned soaking rain for 14 months. We had no winter rains—only snows. The spring rains that we usually have, that stop plowing for days, did not come this spring. Not a single hour was lost on account of wet weather. We had a middling sort of rain on the 3d of July, and that is the last. Every thing of the grass kind is dried up. Our pasture fields, blue-grass sod, and timothy and clover, are as dry as the highway, and almost as dusty. Yesterday, as we rode along past the woods pasture, Jessie said, "That pasture is rather low, isn't it?" We all laughed—"rather low" was pretty good where not a spear of grass could be seen, and a great cloud of dust rising up whenever the sheep walked about. We pump our stock-well dry every day, and then water the cows and calves at the house-well. Our pastures dried up the second week in June, and we have been feeding dry hay and green corn ever since. We had just six weeks of green pasture this year—a pretty short summer. We live away from the public highway, and all the dust we get at home is of our own raising; but as it is, we get enough. We can hardly get the washing dried without having it all covered with dust, and it comes into the house, and settles on every thing. They say dust is a good disinfectant. I feel sure that we have had enough dust sprinkled over us, sifted down our backs, and breathed into our lungs, to disinfect us as long as we live.

Last Sunday we went to camp-meeting. Everybody was there. They had a big tank of water, and a great crowd stood around it with tins and dippers and buckets, waiting for a chance. I went up with my two daughters to get a drink. We did not have a tin, and we stood there a good while. Finally a brisk young man, in a striped seer-sucker, said, "Let me have your tin, Henry; here are two ladies who want a drink." Jessie snickered (she is fifteen), and Minnie pressed my arm. The brisk young man held the tin at the faucet till it was full, and then passed it *over my head to the two ladies*. Jessie took it, and, extending it to me, said, as sweet as peaches, "Won't you have a drink, mamma?" And I took it and drank. That was early in the day, while people were yet calm and polite to each other. Before long, when the heat grew intense, they pushed each other away by main force, and jammed and *almost* quarreled over whose cup should be filled first. Then the whole thing ran

dry, and there was not a drop for anybody, and the strong were no stronger than the weak.

There is a mineral well on the camp-grounds, but the water is sweetish and saltish, and sourish and bitterish, and very few like the taste of it; but then, everybody drank it, and it was fun to see the wry faces and the spitting and sputtering.

I do not see how bee-keepers can afford to go to conventions. I can not. I paid out \$35.00 for hives and foundation, and we have not a pound of honey to eat. Won't some brother be kind enough to pass around the hat? MAHALA B. CHADDOCK.

Vermont, Ill.

Why, Mrs. C., do you really mean to say you had such a state of affairs at a *camp-meeting*? Had it been at a circus, or even a political meeting, I should not have been very much surprised; or had it been a temperance meeting, it would not have been so very strange, where the people wanted to show their zeal for cold water. You did not tell us any thing about the sermon; but the text surely could not have been any thing about "in honor preferring one another." We hope the preacher was not too severe on the three or four millions of Israelites who, when they came into the "great and terrible wilderness, wherein were fiery serpents, and scorpions, and drought, where there was no water," murmured against Moses; for if the Israelites simply murmured, surely the people of Illinois should not strive. It seems to me that water-tank must have afforded an excellent opportunity for people to show their Christian spirit. And now, my good friend, have you not omitted to mention that a great many *did* show a spirit of self-sacrifice, and stood back and went away thirsty, because they preferred to suffer rather than to see others suffer? When Jesus stood at the well, waiting for water, and, if I am correct, not getting any after all, he spoke these wonderful words: "Whosoever drinketh of the water that I shall give him, shall never thirst." I do not know that I have ever been where there was not water enough for the crowd to drink; and if I should ever get in such a gathering, it seems to me I should enjoy the opportunity of furnishing water myself for all who might care for it. A few days ago it was mentioned in my hearing, that they were selling lemonade and pies at their camp-meetings, and this, too, on Sunday. I remonstrated. My wife took me to task, and asked if I were not uncharitable, suggesting that people who were from a distance must have refreshment. I replied that, under such circumstances, they should have crackers to eat and water to drink; and if anybody was not willing to pay for the crackers I should enjoy footing the bill myself. I am very glad to hear you had such a gathering at that camp-meeting that the supply of water provided was not adequate; but I should be still more glad to hear that that great gathering drank of the water of life as well as of the water contained in the tank mentioned. Had they striven as eagerly for the water of life, "flowing, freely flowing," as they did for the natural substance, it would have been a beautiful comment on Christ's words, "The kingdom of

heaven suffereth violence, and the violent take it by force."

COUNTING CHICKENS BEFORE THEY ARE HATCHED.

DOOLITTLE'S SWARMING THEORY NOT HOLDING TRUE.

I NEVER came as nigh getting a big crop of honey in all my life as I did this season, and yet miss it entirely. I commenced the season with 55 colonies, some strong and some weak. They were like the fellow's fence-rails. He said some of them were too long and some too short, but they would make a good average. Well, by the first of May the most of them had built up to be quite strong and ready for swarming or storing bushels of surplus honey, or any thing else they might take a fancy to. I, being in high spirits, had all my oars with the right sides up to catch the honey shower whenever it should come; and even my grocer, who has sold honey for me for several years, had promised to sell for me this year for nothing, because he said it was an advantage to his business. You have heard the proverb, "Never count your chickens before they are hatched." Well, I couldn't count mine; they were too numerous—in my imagination; but I can count 'em easily enough now. From 55 colonies, spring count, I have 7 good swarms, and had 55 one-pound sections of empty comb filled with nice honey, and the bees are all in good condition now and ready for the fall flow of honey, if it comes; but that "if" is in the way, and I can't move it; for we never do get any surplus here in the fall after a very dry summer. Now, do not put me in Blasted Hopes, for I am not one of the blasted kind. You had me in there once, and I didn't stay there three months. You can't keep a fellow in there who has any get-up about him, and it's no use trying. Suppose you could, there's enough of us here in this township in about the same fix to fill up the whole department. According to the assessor's report there are or were in this township, before swarming was over, 550 colonies of bees, divided perhaps among one hundred owners, and I have not heard quite as good a report from any of them as I make myself.

Mr. Doolittle's theory of swarming does not agree with my experience and observation; in fact, his rule, page 434, is the exception, and his exception is the rule all through the season from first to last with me, be the apiary large or small, and be the bees black or white, yellow or brown. Here are the facts of this season's observations: Out of 7 swarms in an apiary of 55 (all natural swarms), the first came out on the 10th of May; and if they had any queen-cells at all there was nothing but eggs in them, because it was fully sixteen days from the time they swarmed till there was a queen hatched in the old hive. The next five had queen-cells more or less advanced, but none capped till the 7th. The last one came out on the 15th day of June, and left capped queen-cells almost ready to hatch. From these facts I infer that the rule laid down by Mr. D. for the benefit of beginners is more likely to mislead than to benefit them, and these facts from my experience of the past season are not exceptional, but rather corroborative, of my last sixteen years of modern apiculture. JACOB COPELAND.

Allendale, Ills., Aug. 9, 1887.

ANOTHER USE FOR THE CHAPMAN HONEY-PLANT.

A NEW OIL EXTRACTED FROM ITS SEED.

WE take the following from the *Buffalo Express*, of Aug. 8, referring to the Chapman plant as an oil-producer as well as a honey-producer:

Some years ago a Mr. Chapman, of Marcellus, N. Y., while spending a winter in Florida, gathered a large quantity of seeds of various kinds; and on his return to the North in the spring, he planted them in his garden. Among the plants which sprang therefrom he noticed one which had never been brought to his attention in the tropics. It grew up a strong thrifty plant with large prickly leaves, somewhat like those of a thistle, but the first year failed to blossom. The following summer, however, it bore about 30 compact ball-like flowers, from one to two inches in diameter, which emitted a fragrant odor and proved an irresistible attraction to all the bees in the neighborhood. Indeed, so great was the excitement of the honey-gatherers over the floral stranger that Mr. Chapman one day kept account of the number of visits paid a single blossom from sunrise to sundown, and the visitors' register showed 2170 calls. Because of this peculiarity the plant was christened the "honey-bee plant," and by this name, or by the commercial title of "Chapman's honey-bee plant," it has become widely known among the bee-keepers of the country. It has been ascertained that the plant is a native of Southern France, where it is treated as a weed.

Believing that the seeds of the plant would be in active demand as soon as its qualities became known, Mr. Chapman saved the seeds from the original and planted them the following season. This was repeated again and again until he now has ten acres under cultivation. The plant flourishes in a clay soil, which will raise nothing else save thistles, and is so hardy that a failure of the crop need never be feared. The seeds are now in active demand among bee-keepers at a dollar a pound.

Some time ago the seeds of the honey-bee plant, which resemble oats in form, were brought to the attention of Mr. F. S. Pease, the well-known oil-dealer of this city, who is the authority for the statement herein made. He perceived that they were rich in vegetable oil. Learning that the plants grew with very little attention, and produced a large quantity of seed which could be easily beaten out from the balls, the idea occurred to him that possibly the plant might some day hold a prominent commercial position as an oil-producer, thus serving a double purpose during the period of its existence. Acting upon this thought, Mr. Pease two years ago procured a quantity of seed and extracted therefrom the oil for experimental purposes. It was found to be equal to the best linseed oil for all purposes, but in its qualities more closely akin to the poppy-seed oil. It does not solidify, and shows no disposition to acidulate. A two-years' test has demonstrated that it has a commercial value equal to linseed oil.

This raises the question as to whether it can be manufactured profitably. The linseed-oil cake which comes from the compress after the oil has been extracted is a valuable commercial product. The residuum of the honey-plant seed possesses qualities so closely allied to quinine that the taste and after-effects are apparently almost identical with those of the costly drug.

To determine the full value of his discovery Mr. Pease will go to New York this week, accompanied by Mrs. Pease, to attend the meeting of the American Association for the Advancement of Science. Mrs. Pease will read a paper in the botanical section upon the honey-bee plant, while the oil itself, and the bitter residuum left after the extraction, will be brought to the attention of the chemical section.

Should the honey-bee plant prove worth cultivation for its honey, oil, and quinine substitute, some of the farms in Erie County which are now scarcely worth the taxes paid for the privilege of being a real-estate owner, may experience a rise in value such as comes with the discovery of mineral oil beneath the most barren soil.

The question now arises, Can this seed be raised cheaply enough to compete with flax

seed? From what I know of the two plants, I should say it can not. I may, however, be mistaken. The Chapman honey-plant also requires two seasons, while flax requires only a small part of one season. If its bitter quality can compete with quinine, and answer the same purpose, there may be a great opening in this line; that is, if quinine is to be used to the extent it has been. The yield of honey from our plants is about the same this year as last. The blossoms came fully two weeks earlier; in fact, it began to blossom before the basswood yield was over. Friend Chapman had a sample of the oil at the Indianapolis Convention, and he has also a home-made machine for extracting the oil. A small quantity of seed gives a comparatively large quantity of oil.

REPORT FROM E. FRANCE & SON.

EXTRACTING TOO CLOSELY IN THE FALL.

LAST year we got 42,000 pounds of honey; this year we got 5000 pounds, with a fair prospect of having to feed it all back, or its equal in something else, to winter the bees. We will feed sugar if we can not get honey. All we are trying to do now is to keep the bees alive until another year.

The following is the number of colonies in the fall of 1886 and spring of 1887:

Water's yard, fall,.....	89;	spring of 1887, 68; loss.....	21
South yard, fall,.....	69;	" " 58; loss.....	11
Adkinson's yard, fall,.....	94;	" " 45; loss.....	49
Cravin's yard, fall,.....	113;	" " 104; loss.....	9
Burney's yard, fall,.....	76;	" " 74; loss.....	2
Home yard, fall,.....	66;	" " 61; loss.....	5
Total,.....	507	410	97

The spring of 1887 opened out well, and we expected to get a good crop of honey. We had every thing ready. We moved bees from the Cravin yard to the south yard, and to the Adkinson yard, to make them more equal in numbers. We moved the whole of the Burney yard two miles on to Mr. Gunlow's place.

We had kept bees at Burney's 20 years. Then why did we move them? The timber had been cut away since I first located the yard there, leaving it too windy. But we lost only two out of 76—the best showing of any of the 6 yards. I will tell how that happened, further on. Another reason for moving them was to get more room. We never had over 50 colonies, spring count, and at Burney's we wanted room to keep 80. We can carry help to work 80 colonies in a day, and we want to work all our yards up to that point. By the above report it will be seen there is a big difference in the winter losses, Burney's being the best and Adkinson's the worst.

I think I know just where the trouble lies. We went over all of our bees last year in just a week; that is, all were extracted every week—just a week from one extracting to the next—for each yard. We commenced to extract first, from the Waters yard; on the next day from the south yard; on the third day from Adkinson's; on the fourth, from Cravin; then from Burney, and last at home.

HONEY-DEW A BAD WINTER FOOD.

We kept the same rotation through the extracting season. We had here, just at the close of the basswood run, a great flow of honey-dew—very dark, thick, sticky stuff. When the bees failed to obtain

any thing from the basswood they commenced on the honey-dew and filled all the empty room they had with that miserable truck. Those that got the most fared the worst. When we commenced to extract the last time around, we thought the basswood was good for a week yet, during which time the bees could fill their hives. To make sure, we left in each hive two full combs of good basswood honey in the Waters yard, for it is two miles from basswood. They soon left the basswood for honey-dew. By the 29th of January the bees in that yard had a fly, and showed that they had the dysentery badly. But from the fact that their location was in a warm valley (which gave them a chance for a cleansing flight quite often) they would have all died.

But, to return. The next day we extracted the south yard. We left in about one-fourth of their honey. They were well located in a warm valley, with basswood all around them. But in that place the basswood was earlier, and, as a consequence, ceased yielding nectar early. But the bees which were filled up with honey-dew had dysentery badly, and ran down to very weak colonies, 11 of them having died. The Adkinson yard was worked in the morning of the same day as the south yard, but we took out about all the honey. The celebration for the 4th of July was on the 3d, as the 4th came on Sunday. We were making three days' work in two days, so we traveled to get to the Adkinson yard before daylight in the morning, and could not see how far along the basswood was, and hence we made a mistake. We took out too much of their good honey, and left them to fill up with honey-dew, which they did, and over half of the bees in that yard died in consequence. Right here we quit extracting, and see the results. Out of the Cravin yard of 113 colonies in the fall, we lost nine, four of them being queenless. Out of the Burney yard of 76 colonies we lost only two, and one of those was queenless. The home yard, Cravin yard, and Burney yard all came through healthy and strong. There was not a single case of dysentery in any of the three yards. They all three had *plenty of good basswood honey to winter on*. The other three yards had but little good honey, and wintered mostly on honey-dew. Some kinds of honey-dew honey may be good for bees to winter on, but I am satisfied that what we had here won't do. It was gathered from the oak. Bees wintered about here in cellars were no better off—nearly all died. One man had 37, and lost 30. Another had 50 and lost all; still another had 30 or 40 in the cellar. He lost all. He was extracting clean a week after we quit. They filled up with honey-dew and died. E. FRANCE.

Platteville, Wis., Aug. 11, 1887.

Friend F., you give us a very valuable set of facts indeed in regard to this matter of extracting too closely in the fall. With the number of apiaries you have to work, you have an opportunity of getting results that are almost without a possibility of mistake, and correct in the deductions. I do not think, however, it was entirely the fault of the honey-dew. Many years ago we extracted very closely, just as you mention, and the bees died badly, although we had no honey-dew at all. The next season we worked for increase entirely, to build up our shattered fortunes, or, rather, our dwindled colonies. Every pound of honey gathered was

capped over and ripened in the hives, and saved for winter stores; and although we increased from 11 to 48, not a colony was lost. We have since had opportunities of testing the matter, and we have always found much the best results in wintering where we stopped using the extractor a week or two before the honey-flow entirely ceased.

REMOVING SECTIONS FROM THE T SUPERS.

IS THE SLATTED HONEY-BOARD A NECESSARY IMPLEMENT IN THE PRODUCTION OF COMB HONEY?

THE late numbers of GLEANINGS have had several articles on removing sections from the T supers, by Dr. Miller and others. We have used them quite extensively in our apiaries for the past four years, and I should like to have some of our brother bee-keepers tell me what the object is in removing them all at once. We always clean our sections as we remove them, one at a time, and then they go right into the shipping-case. If we do not have our shipping-case ready when the crates come from the hives they are packed up on each other, with a sheet of paper between them to catch drip if any; but we hardly ever have any.

In GLEANINGS of July 15th, Ernest says, to use it without the honey-board would be simply intolerable. After using them both ways, we much prefer to have no honey-board under our sections; for by experimenting we are convinced that much more honey can be obtained, especially in a poor season like the past, by the non-use of honey-boards of all kinds. I could not but notice how much sooner the bees commenced in the sections, without any honey-boards to crawl through. If the bee-space between the brood-frames and sections is right, and the bees are not crowded for room, they will not build any comb to speak of between sections and frames; and when we wish to examine brood-frames below we do not have the trouble to pry off a honey-board in order to do so. We have never practiced contracting to any extent, as we do not see any advantages obtained in so doing; for by using eight-frame hives, 12 inches inside measure, we can secure all the honey we ought to take from the bees, and then we do not have to be to the trouble of feeding for winter, and by so doing have so much trouble by bees robbing each other. We rarely ever have a case of robbing, as we do no feeding, unless a few colonies need a little to help them in the spring.

The past season has been a queer one. We never saw half as much white clover; but, as a great many have reported, it did not secrete any honey, owing, we think, to cool nights and too much rain. If it were not for blue thistle coming in bloom about June 15th our crop of honey would have been very small. As it is we have secured half a crop of nice comb honey, and hope to realize more for it than a full crop last year.

H. W. BASS.

Front Royal, Va., Aug. 15, 1887.

It seems to me, friend B., there is considerable advantage in removing the sections all at once, or *en masse*, as Dr. Miller terms it. By removing all the sections at one

time, and cleaning them at another, we secure some of the advantages of the division of labor, so called. If you take the sections out one by one from the T super, you will have to fuss a while before you can get out the first one; and I feel quite sure that, by Dr. Miller's plan, we can remove *all* the sections at one operation while you are taking out three or four by your plan. We tried the doctor's plan of emptying the T super, as he describes it on page 249, and were very much pleased with it.—On page 556 I said, that to dispense with our slatted honey-board would be simply intolerable, and I think so yet. I grant there is a possibility of getting perhaps a trifle more honey; and it is possible, also, that the bees would enter the sections a little sooner; but how about the burr-combs which the bees would surely attach to the exposed bottoms of the sections? When you come to tier up, placing a super of empty sections under the one already partly filled with honey, what do you do with the burr-combs that are attached to the bottom of the sections in the super? Although I knew what would be the probable result, I tried it this summer, just to see how it would seem, and I vowed I would never do it again. In pulling up the super, the lower brood-frames stuck and dropped down, as one of the boys proceeded to slowly tear away the super from off the brood-nest. The bottoms of the sections were covered with little chunks of honey, which dripped and drizzled as he handled it. Now, suppose we had put an empty super in its place, and placed this dauby super on top of the clean one, about the time we had secured our crop of honey we should have had our two supers stuck and gummed together. Why, it seems to me that, to run say 100 colonies in this way, without slatted honey-boards, would be "*intolerable*" indeed. You say that you have used the T supers quite extensively for the past four years. Did you not, when you dispensed with the use of slatted honey-boards, use a super something like our combined crate—that is, one having slats in the bottom, upon which the sections are to rest? If you did, then the task of securing comb honey may not have been so intolerable after all. Still, even then I should prefer the slatted honey-board. Is there any one else who can secure satisfactory results with the T super or Heddon case, without the slatted honey-board? Perhaps Dr. Miller or Mr. Heddon or W. Z. H. will say what they think about it.—With the eight-frame hive, contracting is not so essential as with the ten-frame hive. Still, I think that taking out two frames and replacing them with dummies must be decidedly an advantage. If I am correct, it is the practice of some of those who use contraction to fill out the brood-nest to its full capacity, just as the honey-harvest has nearly come to an end, so that extra brood-frames may be filled with honey when the inflow has entirely ceased.

In addition to what Ernest has said above, I would remark that, by the use of the slatted honey-board, a case of sections comes off at any time with perfect ease—so much so, that at one of our Michigan conventions a one-armed friend said he could pick up

any case from any hive in his apiary, filled or not filled, with his single hand, and could do it without any difficulty whatever. If you omit the slatted honey-board this would be absolutely impossible.

APIFUGE AND ITS DERIVATION. AGAIN.

SOMETHING FROM OUR FOREIGN FRIEND, MR. GRIMSHAW, THE ORIGINATOR OF IT.

DEAR SIR:—I observe in July GLEANINGS that you make some remarks on my discovery, apifuge; and as they are somewhat misleading (through inadvertence, I doubt not), perhaps you, with true international courtesy, will permit me to direct you and your readers into the right path.

The word "apifuge" is derived from *apis* (a bee) and *fugeo* (to avoid, retreat from, leave alone, etc.), not from *fugo*, to scare or put to flight. This I well explained in the *British Bee Journal*. It therefore, is not, as you say, a bee-scarer, for its effects on them are of quite a passive and pacific character. If bees liked it they would cover the hands, etc., and be a nuisance; on the other hand, if they disliked it they would sting. As it is, "they who come to scoff remain to pray," for bees dart at the hand sometimes, intending to sting; but in an indescribably short time they sample, so to speak, the surface before inserting the dart; and, finding this strange substance on the skin, submit to its influence and fly away.

I must say, that I was in a measure disappointed at your testimony being so mildly favorable, considering your impartiality, and although you yourself did not get stung whilst manipulating a lot having Cyprian blood in them. I judged you selected a Cypriote lot in order to fairly test "apifuge," and, finding it answer, I repeat I felt chagrined that you did not tell us of its success. I should like you to try it again on the very worst demons you have, and judge whether or not bees will sting the skin on which it is rubbed, so long as the perfume of apifuge remains. It is no small recommendation, that it is not only a preventive against, but a cure for, stings.

RATT. GRIMSHAW.

Crag Hill, England, Aug. 1887.

Most certainly, friend G., we are quite willing to be directed in the right path. If our readers will permit, I will take a little space here to discuss some Latin derivations. The formation of the word "apifuge" is such that it can be derived from *apis* and *fugo* as well as from *apis* and *fugio*. (The latter you write *fugeo*; do you not mean *fugio*?) It seems to me that *fugo* would be a more natural verb from which to derive the suffix. For instance, "vermifuge," a substance for expelling or driving out worms, takes its derivation, according to Webster, from *vermis*, a worm, and *fugare*, to drive away, to route, to scare, to put to flight. If we translate "apifuge" literally, as derived from *apis* and *fugio*, our English equivalent would be "bee-avoider;" that is, the liquid itself avoids bees. In other words, are you not putting the cart before the horse? However, I do not know that it makes any practical difference one way or the other; but I should prefer to have the suffix derived from *fugo*, as is the suffix in the case of vermi-

fuge. I am sorry if what I said was so mildly favorable to apifuge as to detract from its real merits. As I stated on page 517, I can not help thinking yet that the behavior and the control of the nerves has more to do with the prevention of stings on the hands of the apiarist than any liquid that can be compounded. Again, I can hardly think that any preparation smeared over the hands or on the face would prevent any bee, that was fully intent on stinging, from accomplishing his purpose. Many times have I seen a Cyprian mark out his spot of attack at long range, and, without the least shadow of preliminary as to whether this or that spot was softer or more desirable, he would strike tail foremost. From my experience with the liquid I hardly think the "Cyp" would have changed his mind. Let us you may still think I am prejudiced, I take the following from the pen of one of your own countrymen, as found on page 348 for Aug. 11, of the *British Bee Journal*:

"In answer to 'E. W. P.' (1164), you think that apifuge would have more effect than smoke or carbolic fumes. Well, I for one should be inclined to doubt it. Two years ago I got some bees of a neighbor, who said they were so wicked he could not manage them. I found smoke of little use; they retreated before volumes of it, but always returned to the charge whenever the smoker was laid down. Then carbolic-acid fumes were tried, and had some effect, but were not quite satisfactory, because these bees would, under the influence of the fumes, allow the hive to be opened and some of the frames to be lifted quietly, then all of a sudden they would attack in a cloud. I still kept this breed of bees, because they were such good workers, though almost unmanageable, and dangerous to passers-by on the road near.

When apifuge came before the public, I hastened to get a bottle, and, after donning a veil, rubbed my hands and wrists with this invisible soap, and proceeded boldly to the "wicked" hive. Gently I turned back the quilt, spread out my hands to bless them into peace and quietness, but I think there was some mistake amongst those bees, because they never stayed to feel the pleasant scent of apifuge. Straight they shot at face, hands, and body; and sting! did they not? My hands were about covered with their lances, and they went at my clothes in perfect madness. I didn't run, I am too well hardened for that, but wince I did, till I got a knife and cleared the back of my hands from poison-bags. Not to be beaten, I again put some apifuge on my hands, and with no better results, so closed that hive as soon as possible. That apifuge is useful in some cases, I know; but, after repeated trials, I think that it is utterly useless with these particular bees. I disturb these bees as little as possible now, and when I do, always using a cloth saturated with carbolic acid. I may say that these bees are crossbreds, black, with just a touch of Ligurian, the queen being very black.

GEORGE D. CLARK.

Kirklandhill, Dunbar, Eng., Aug. 1, 1887.

AN A B C SCHOLAR'S EXPERIENCE.

THE SUPERIORITY OF ITALIANS DURING DROUGHT.

I COMMENCED bee-keeping a year ago, at which time I bought 18 full stocks, ten of which were Italian. Again last February I purchased fifteen colonies of blacks. I allowed seven of the Italian colonies to swarm this spring. I now have forty colonies in all. On the 8th of April two swarms came out, and I hived them successfully; and after a day or two I discovered that neither had queens. Can you account for this? I gave them queens, and they did well in building up strong. I am now Italianizing all my blacks, giving them first-class queens.

This is an "off" year in this county for honey. We usually commence extracting about the first week in May, and extract every eight days until the 10th of June. This year there has been no extracting in the best localities. During the second week in May, Italians and blacks filled up the brood-chamber and then stopped short off. Italians held their own and increased a little, while the blacks have lost all they did have. They have plenty of bees, as I have not allowed any of them to swarm. My Italians last fall gathered considerable honey, while my blacks had to be fed. I am done with black bees. It was cold here all during fruit-bloom last spring, and we had a killing frost that resulted disastrously to peaches; then it was dry from the first of March to the middle of May. This, I think, is the cause of failure in the honey crop.

I am the only man in our county who has Italians. If it had been a good honey season I would have increased to about eighty colonies. My apiary is situated in the town of Madison, and it is quite a curiosity to some people here who never saw an apiary. My hives are all painted white, and arranged just the same as shown in the cut on front of your price list and catalogue. A young lady was out riding, not long since, in my neighborhood, and spied my apiary afar off. She suddenly exclaimed, "Oh! I did not know there was a cemetery in this part of town." She is a stranger here.

There is no trouble in wintering here if the colonies are strong and have plenty of stores. We just leave them on their summer stands, and they go safely through the cold. R. H. CAMPBELL.

Madison, Ga., May 28, 1887.

I believe it is a common thing, friend C., for strangers to call a well-kept apiary a "cemetery." This is oftener the case where Simplicity hives are used without grapevines. Since our grapevines have grown up, people, in passing through our town on the cars, are not nearly so apt to call our place a cemetery.

A LETTER FROM AUSTRALIA.

HONEY AS A FRUIT-PRESERVER.

I ENJOY GLEANINGS thoroughly, particularly now that you have added the articles on gardening; for, with the exception of work among the bees, nothing makes me happier than poking and rooting about in the garden. So GLEANINGS gives me double pleasure now. I must also thank you for your A B C. It has been a great help to us; but, plain as it is, I don't know that we should manage so well but for the advice and practical hints we get from our good friend Mr. Garrett, who has done more for bee-keeping and bee-keepers than any one else in the colony. Mr. Parker, of Glenbrooke, and Mr. Hudson, of Bathurst, and others like ourselves, have secured very great assistance from him; and among other good things he introduced us to Mr. Root and the Home of the Honey-Bees. Inspired by what you said about growing vines, I got eight young vines in the middle of summer—quite the wrong time to do it, and by patience and great care I have managed to rear six fine strong plants; the other two look delicate, but I have hopes of even them; at any rate, I won't give them up as long as there is a green twig left. Our bees have not done so well

this year as we hoped they would. It has been a very wet season, but we must not grumble, as it has been preceded by many years of drought; but, unfortunately, the bees, particularly the Italians, would insist upon throwing out their brood after it had been raining a couple of days; and this, with plenty of stores in the hive. I had actually to feed them with honey to coax them to leave their brood alone; and even this did not always have the desired effect.

We have made some foundation with the comb-mill, and we think it is very nice; in fact, we often stop work to admire it, it does look so very pretty, and we find the bees like the fresh home-made wax much better than what we got from New Zealand, for they will work eagerly on the one when they won't touch the other.

Among the many ways of utilizing honey, written about in GLEANINGS, I have not noticed that any one advocates its use for preserving fruit. I know oranges, both whole and as marmalade, are simply delicious, preserved in honey, and so are mangoes. Now, why should not Mrs. Chaddock or Mrs. Harrison try it with some of your beautiful fruits, or dear Mrs. Jennie Culp. I am sure she could if she tried. I mean to do it, and will tell you how I succeed. I am determined not to fail. Who knows but that I may send you some to taste?

SOPHIE A. BRADLEY.

Campbelltown, Victoria, Aus., Feb. 22, 1887.

MORE ABOUT BLISTER-BEETLES.

A BLISTER-BEETLE THAT COMES AS A FRIEND INSTEAD OF AN ENEMY.

I WAS much interested in Prof. Cook's account of the blister-beetle larvæ on bees; and thinking that perhaps some of the readers of GLEANINGS might come to the conclusion that the insects of this family are all injurious, I send a few notes on the habits of some species closely related to the one of which Prof. Cook writes.

During the summer of 1885 a large part of Central Illinois suffered from an outbreak of two or three species of our common grasshoppers, many farmers having their crops almost wholly destroyed. As many people throughout the infested region feared that the insects would be present the next season following in overwhelming numbers, I was instructed by Prof. S. A. Forbes, State Entomologist, to investigate the condition of the grasshopper eggs late in fall and early in the spring, in order that we might know what probability there was of serious damage. The grasshopper eggs are small, yellowish, cylindrical objects, about a third of an inch long, and are laid in masses, or "pods," containing fifty to one hundred eggs each. These pods may readily be found in sod land, about an inch below the surface; and by examining a sufficient number of them at any one time a very fair idea of the percentage of embryo grasshoppers then alive can be obtained. In the investigations mentioned I found a large proportion of the egg-pods to contain a peculiar whitish grub which was leisurely eating the eggs about him, having generally already destroyed from one-half to three-fourths of the eggs in the pod. These were the larvæ of the blister-beetles, which had been very common the summer preceding, and had entailed so large a progeny upon the land that, aided by a common red

mite and two or three other insects, they so entirely checked the grasshopper outbreak that the pests were very scarce the succeeding season.

These blister-beetles are often known as the "old-fashioned potato-bugs," and have a life-history similar to that described by Prof. Cook for *Mela*, except that they attack grasshopper eggs instead of bees. Their very curious life-history was first worked out by Dr. C. V. Riley.

These insects are very abundant throughout the West the present season, and are doing considerable mischief (perhaps as compensation for the good they did when young) by eating potato and tomato vines, cabbages, beets, corn, and, in fact, almost any green thing they can find. They can be driven out of small fields, much like a flock of chickens—generally a better method than poisoning them, because we can not afford to dispense with the services of their young as grasshopper-destroyers.

C. M. WEED.

State Laboratory of Natural History, Champaign, Ill.

ENTRANCE - SCREENS TO PREVENT ROBBERING.

FRIEND HAYHURST GIVES US A VERY VALUABLE SUGGESTION.

FRIEND ERNEST:—When reading "A Caution to Beginners," on p. 598, the thought occurred to me, "I wonder if I can not give E. a little lift in that matter." Suppose you try my way of circumventing the thieves. Out of some quarter-inch stuff, two inches wide, make five or six little frames, six inches in width, and as long as your hives are wide. Tack pieces of wire cloth on one side of these, thus making screens to be adjusted over the entrances of your hives. This can be done quickly by "toeing" a wire nail through each end into the front of the hive. When you remove the tent from a hive just operated upon, allow time for most of the flyers to get into the hive, then shut out the robbers with one of these entrance-screens, which may be left in place until you have gone through five or six more hives, by which time the first one will have matters straightened up and be ready for battle if necessary. The screens should be made at least as large as mentioned, so as to allow some of the bees to cluster outside of the entrance if they wish to; and in very hot weather, with the sun shining directly on the hives, it is not safe to leave the screens on very long, else the bees, finding themselves shut in, may start to "running" and soon smother.

I have used these screens for a number of years, and they have enabled me, on many occasions, to put up from twenty to thirty or more 1-lb. packages at a time, regardless of the weather or time of day, and at seasons when it would be sure to start robbing if I should attempt to put up one package in the usual way.

E. M. HAYHURST.

Kansas City, Mo., Aug. 12, 1887.

As I have already had something similar, I feel very sure your plan will work. I infer from your description that you are using a hive with a Langstroth portico. It is a pretty difficult matter to close the entrance of a Simplicity hive with any kind of wire screen. However, I will try to put your plan, in some form, into execution, and give it a thorough trial.

THE BLESSINGS OF A SHORT CROP OF HONEY.

ABSCONDING SHORTLY AFTER SHIPMENT.

YOUR old reliable Mr. W. Z. Hutchinson, in your July 15th No., has been aiding you in putting backbone into some of us. We were getting ourselves into position to do some small blowing on humbuggery of bee-keeping as an aid to family support; but his suggestion, that a failure in crop may not be fully a failure in purse, and that the little honey made may bring as much as a larger yield would, braces up our sanguine temperament, and we have no bees for sale yet. Another year may serve us better; if not, you may have opportunity to advertise some cheap pure Italians.

About one year ago, though late in the season, we determined to purchase 20 swarms of bees, and do as others had—make money, or an attempt at it. We soon had ordered from Charles D. Duvall, Spencerville, Md., 10 swarms by express, which came to hand promptly and in good condition, excepting 2 inside cages were overheated, and two-thirds perished. They arrived about noon; and as soon as practical all were transferred into good eight-frame hives; and before night, work was going on as though they were still among their native hills. At 11 next day, one colony became dissatisfied, and, without giving a reason or warning, abruptly left the hive; but we soon took them from a pear-tree near, and, after putting them back, seeing discontent, we closed the hive till near night, then gave them their freedom. Next morning, about 7, they dropped from the hive, and within one minute were hastening toward the east, in spite of much water thrown among them. Some few were shut up in the hive, but the swarm was lost. A few hours later (Sunday morning, of course) two swarms more came out, mixed up, and alighted together on the heavy fork of a pear-tree. Though not quite tyros in the business it was not pleasant to get these bees into two hives again, neither was it profitable; for by 10 next day they left by the same route of their fellows the day before. In short, five of the ten swarms left, all taking the same easterly direction. If going by instinct to their old location, they should have gone northwest.

About this time, Aug. 20, our second importation arrived from South Carolina, by express. They were transferred without trouble, and appeared to enter right into the spirit of their calling; and though late, many of them laid by stores sufficient for the winter. Others, weaker and less active, had to be fed to carry them through. What much surprised us was, that in April, after the bees had been working at least a month, we found one swarm dead and another nearly so—starved to death. They had apparently been so engaged with their brood development as to overlook their supply of food, and a few cold non-working days ruined them. And now the outcome: The thirteen colonies fully wintered have given us but four new swarms, and they were mostly late; the last, July 27th. Most of the brood frames are well filled with winter stores, but the honey-boxes have received but little attention, a few being nearly filled, but none yet completely capped.

During our long heated season the bees have hung out, fanning themselves, apparently trying to keep cool, while care for the future did not seem to

enter into their calculations. For fully a month their stores have not increased, and some have been living on their earlier gatherings rather than expose themselves to "sunstroke." I should think the richest honey should be gathered in hot weather, but the bees ought to know. J. C. FRISBEE.

Suffolk, Va., Aug. 15, 1887.

Friend F., it is very strange indeed that so many of your colonies swarmed out and went off in the same direction. I know it is a fact that bees, after having been shipped or moved, sometimes take a notion to desert their hives; but I don't know that I ever heard of so many following suit. You probably will never have a like occurrence again.—I think W. Z. H. was right, for the small crop of honey has made a stir and excitement in the honey-market, such as was never known before since I can remember. It is now called for and bought up at good prices as soon as it makes its appearance, and I should not be surprised if prices go up a good deal higher than they are now before another crop comes to our relief. We are sold out here at the Home of the Honey-Bees about all the time, with the exception of our carload of California honey that we have had for several years, and some extra nice comb honey which we are selling at 18 cents a pound wholesale. We are now offering 7 cents for basswood honey, and 8 cents for a nice article of clover, delivered here; and if it does not come at these prices we shall have to keep raising.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

QUESTIONS BY A BEGINNER.

THIS is my first year with bees. I bought four colonies last fall in 10-frame portico L. hives. They were buried during winter according to the instructions of a local bee-keeper. They came out in spring rather weak; but as the hives were full of honey they built up rapidly. One hive cast a swarm in June; and as others were clustering and had queen-cells nearly ready to cap over, I swarmed them artificially as per the A B C book. The colony that swarmed naturally also swarmed again in a few days. I saved all, and now have nine, with but very little honey. The four I bought had over 160 lbs. of honey to go through the winter on, but I weakened the parent stocks by taking out frames containing both brood and honey, for the artificial swarms; and also one frame each for the natural swarms. Basswood was budded heavily; and as we had plenty near by we supposed they would at least fill their brood-frames with winter stores. They worked like beavers while the basswood lasted, but there are still some empty frames, and some with a little comb and honey. Now, I study the A B C and GLEANINGS, and am well paid for all time so spent; but it is somewhat like a beginner joining an advanced singing-class—all very interesting and fine; still, one feels the need of the rudiments. For instance, I might open every hive I have, and I could not tell whether it were better to unite the swarms or to feed them for winter. Neither could I determine the number of frames to leave in the hive;

whether it were best to contract or not, and to what extent. A writer in the *American Apiculturist* of last year said he aimed to have all brood hatch by Oct. 1st, as he wants no "baby bees" for wintering. He does not tell how to control brood-rearing, and I am yet in the dark. Now about wintering. I don't care to go to the expense of chaff hives. Can I not safely pack chaff around and over the hives, placing them first all close together? I dislike to bury them, for they came out so weak last spring that I should rather try some other plan.

I do not write this in a critical mood on account of what I fail to find in the A B C and GLEANINGS. They are admirable publications, and no doubt you have gone over the same ground many times before; but a discussion of the best way to manage colonies in this poor year, that are short of stores, and weak, would help me greatly, and perhaps others, just now.

C. H. MURRAY.

Plainfield, Will Co., Ill., Aug. 6, 1887.

Friend M., the things you mention can not be learned all at once. The more your heart is in it, however, the quicker will these difficulties become easy. Perhaps no one can tell you positively whether it is better to unite your colonies or feed them up just as they are. Sometimes one way would be the wiser, and sometimes the other. As a rule, however, safety is on the side of the strong colonies.—I do not think it makes very much difference how many frames you leave in the hives, providing they contain an abundance of stores. It is quite likely, however, that just about so many as the cluster covers, and no more, will be best. So you see the quantity of bees has much to do with the quantity of combs needed.—I shall have to disagree with the writer alluded to. I have induced bees to rear brood every month in the year, by feeding them pollen and honey; and the colonies that raised brood largely clear up into November seemed to winter best. I feel quite sure, however, that it is by no means necessary to have brood-rearing after the first of October. Bees will usually stop rearing brood at that time of their own accord.—Packing chaff around the hives you have will answer just about as well as chaff hives. After you have put it on or taken it off, however, year after year for several seasons, I think you will conclude the chaff hives are a saving of time, and money too, in the end.

A NON-SWARMING COLONY.

We have had a swarm of bees for three years, and have them yet. They have swarmed but once, and then they went back. This is the third summer, and no sign of swarming. We took the bees, not being able to buy. I have tried to have the widow who owns them share the expense of an Italian queen, but she very graciously tells me every time to do as I think best. They have barely lived through the winter, so you see we have solved the problem of successful wintering. Had they been our own, her head would have come off three years ago. She is a drone-laying queen.

Inland, Mich., June 12, 1887. H. T. DAVIDSON.

Friend D., bee-keepers are not usually particular whether bees swarm or not, so they produce nice large crops of honey. Now, I

should not think of replacing the queen just to get swarms. You do not say anything about the amount of honey received. If satisfactory, let them go on. I presume you do not mean by the term "drone-laying queen" that your queen produces *all* drones; for in the latter case the colony is already virtually extinct. Unless the drone-laying queen is removed, and that promptly, the colony is lost.

QUESTIONS ON WINTERING, BY A BEGINNER.

I shall be pleased to have you answer the following questions in GLEANINGS: In a 10-frame Langstroth chaff hive is it best to leave the frames just as the bees have them filled for winter, or would it be better to change the center frames to the outside of the hive, and bring the outside frames to the center, as they are better filled with honey? How many frames should be left in the hive when 10 frames are used? and if any are taken out, how should the space be filled for wintering on summer stands? Do bees sleep? has been a question asked me. The honey crop in this county is less than half a crop, and but very few swarms.

P. M. LITTLE.

New Waterford, O., Aug. 22, 1887.

By all means, friend L., leave the frames just as the bees fix them. They know how they want their stores fixed for winter, a great deal better than you do. The number of frames to be left on the hive depends on the quantity of bees in the colony; but in most cases I think six or seven are quite sufficient, putting a chaff division-board on each side, in place of the combs removed.

BEEES DROPPING DOWN BEFORE THE ENTRANCE.

For information I must appeal to you in regard to my bees. I, as well as one of my neighbors, was somewhat puzzled over our bees on the 15th of this month. On the 15th it was cloudy all day, and rather muggy. Bees worked well on buckwheat (which is out in bloom;) but about 10 or 11 o'clock they appeared to drop or fall in front and all around the hives as far as 10 or 15 feet from the hives. The ground and grass, and, in fact, every thing they could cling to, was crowded with them. They appeared to be heavily loaded. A great many had pollen; and as soon as they would alight they would appear to be overdone. They did not disappear until about the same time next day. I should not have thought so much of it had not my neighbor's acted just the same way. I thought it might be an unusual occurrence, but it may be common.

JOHN W. GODDARD.

Upper Black Eddy, Pa., Aug. 17, 1887.

Friend G., I have seen bees, when heavily laden, drop down around the hives as far away as a yard, or four or five feet, perhaps; and when the weather suddenly turns cool they often get so chilled they stay in the sun until it warms them up before they will go into the hive; but I think I never saw them so far away as fifteen feet around the hive; and I have never seen them away from home at night unless the weather had turned chilly after they went out for food. As you state it, it seems to be something quite unusual. I do not believe that bees usually supersede their queens unless the queen is in some way defective, or fails to keep the combs filled with eggs as she

ought to do, and we have kept queens as many as two and even three seasons. Where they commence queen-cells, it is generally thought to be an indication that they contemplate either swarming or supersedure; but this is by no means always true.

LARGE BROOD-CHAMBERS, TO PREVENT BEES FROM STARVING DURING POOR SEASONS.

This present year, it seems to me, would settle the question of large or small brood-chambers. Ours, 7 Quinby frames, we think none too small, and we wish this year it had been 8, as it is a calamity to us to have our bees run out of honey.

Roseville, Ills., Aug. 15, 1887. MRS. L. C. AXTELL.

I am very well aware, Mrs. A., that a good many colonies could be saved by having the brood-chamber larger; but the question then arises, Is it policy to carry a surplus of honey, perhaps for several years, just because the bee-keeper might be careless, and neglect to look after their needs during a dearth of honey? By no means let us permit the bees to starve. If we have small brood-chambers, we must be more careful, and must look after the wants of our little friends better than if we permitted them at all times to carry a surplus.

IS ALSIKE A HYBRID?

In regard to a discussion between friends Muth and Cory, concerning alsike turning to red clover, I wish to relate a little experience in the matter. I sowed about three acres of alsike with oats. It came up and grew nicely; the second year it was two to three feet tall—a purple bloom, and the bees worked on it strong. The next year red clover sprang up almost entirely. I plowed it under and put in wheat, all but a little gravelly corner, which has sprung up this spring in alsike again. It seems to be a hybrid, crossed between red and white. It first goes to one and then the other. There can be no mistake about the way this clover did. The seed sown was not half as large as red, and a darkish-brown seed.

C. L. GOUGH.

Rock Spring, Mo., June 6, 1887.

Friend G., our best authorities seem to decide that alsike is not a hybrid — see recent articles on this subject in GLEANINGS; we are therefore obliged to conclude that red-clover seed had been for some years in your soil; but the conditions not being just right it had not before germinated. I believe it is a fact, that red clover very often comes up, and sometimes so as to make quite a good stand, where no alsike has been sown at all. A great many times the matter is passed by, without giving it any particular notice, and this is one reason why so many insist that alsike finally turns to red clover.

ABSCONDING, AND LEAVING COMBS OF HONEY AND BROOD.

The six queens arrived safely, and we divided four of our most prosperous stocks, giving them, of course, a queen, which they took. They all appeared to do well. One day last week we found two of the divided colonies had taken flight. Is this a common occurrence, with brood and honey in the cham-

ber, with six combs in each hive? We account for it only by supposing the gathering of honey was slow work for them at this season, and they were discouraged. Do you think it a good plan to work over the bees much? WM. E. PAYSON.

Boston, Mass., Aug. 11, 1887.

Friend P., this is a very unusual thing indeed, to happen in the month of August. I should think it must be caused by the dearth of honey, and I should also suppose there must have been only a very small quantity of honey remaining in the hives.

DO ITALIAN BEES GATHER HONEY FROM DIFFERENT PLANTS THAN BLACK BEES?

On page 36 of the A B C book you say you found Italians apparently just as thick on wild plants after taking away four bee-trees as before, indicating that there were more trees in the same vicinity. Now, I don't understand that. I thought Italians worked on the same flowers, whether they were in a tree or in one of your best Simplicity hives. I don't see why finding them on wild plants should indicate that they came from the woods. L. W. NASH.

Kennebunk, Me., July 27, 1887.

You misapprehend, friend M. Italians do, as a rule, work on precisely the same flowers that black bees do. The point made in the A B C book is this: After I had captured and taken home four colonies of Italians, about as many were found working on the blossoms in that vicinity as before—indicating there were still more stocks of Italians that I hadn't captured. You see, this was when Italians were first brought to Medina County, and only this one swarm had escaped and gone into the woods. Italians will many times be found working on red clover when common bees are almost exclusively on buckwheat, indicating that the Italians more readily get the honey from red clover. This is the only case I know of where the different races choose different honey-producing plants.

BROOD-FRAME MEASUREMENTS.

Will you please answer the following questions?

1. What should be the *exact* width of end-bars of closed-end frames?
2. What is the *exact* thickness of worker-brood comb?
3. What is the *exact* space that should be left between the worker-brood combs as they hang in the hive?

M. A. KELLEY.

Milton, W. Va., July 26, 1887.

The width of end-bars of closed-end frames should be about $1\frac{1}{2}$ inches. In the new Heddon hives which Mr. H. sent us, we notice the width of his end-bars is a scant $1\frac{1}{8}$ inch.—The thickness of brood-combs is usually rated at $\frac{7}{8}$ inches.—The space that should be left between the worker brood-combs should be $\frac{1}{2}$ inch. In other words, the combs should be spaced so that they are distant from center to center $1\frac{1}{2}$ inches. Some, however, claim that the distance should be $1\frac{1}{4}$ inches. The former measurement is the one adopted in the ten-frame Langstroth hive. We can not give you the exact measurements in all cases which you call for, as the authorities differ somewhat. The measurements which Mr. L. gives us, I think we consider about right.

THE DISPOSAL OF SEWAGE.

In regard to the disposal of impure water from closets, kitchens, sinks, etc., only two ways can actually be considered safe. The first is to under-drain a sufficient plot of ground and turn into the cesspool waters a large quantity of pure water. The whole will be absorbed by the earth and vegetation (meadow or muck patches). The plan as stated in engineering books has been successfully carried out. I am inclined to think, that eventually the roots (especially of neighborhood trees) will choke the drains, and require frequent repairs. The other and far the better way is to kill all germs at once with some substance cheap enough. The sulphate of iron (copperas) is said to be the best in all respects, though lime might perhaps do as well. It must be remembered, that, though the dead matter in water is easily decomposed and absorbed by the earth, it is not so, or probably not so, with the living germs. ADRIAN GETAZ.

Knoxville, Tenn., June 23, 1887.

BEES WORKING ON FRUIT.

Can you tell me what makes the bees eat the peaches so this year? They are eating all there are around here. They eat at them till they commence to rot, then stop. Some say it is the Italians, because this is the first time they have eaten them. They trimmed a tree clean for us, and now they are starting on another. The peaches don't seem to ripen as they ought to this year.

How would it do to put an alighting-board on the chaff hives, like the one you put on the Simp. bottoms, only make them about 4 inches wide instead of that V-shaped piece? F. S. BERRY.

Montoursville, Pa., Aug. 6, 1887.

If the bees seem more disposed to attack the fruit this year than in former seasons, I think the trouble is not so much due to the race of bees as to the extended drought which we have had almost everywhere. In consequence of the very dry weather there has been little or no nectar in the blossoms. If you had nice ripe fruit, particularly if it were damaged in any way, I think it was not strange if the bees did attack it, because there was nothing they could get besides the stolen sweets from fruit.—You could make the same kind of entrance on the chaff hive as we have on the Simplicity, but we can not see that there would be any advantage in it. On the other hand, there would be several reasons why it would not be as good. The alighting-board to the Simplicity hive might afford a good place for the bees to alight, but it would not answer at all for contracting the entrances as can be done with the Simplicity. Again, it would project out too much; and, furthermore, it would be much more expensive than the little V-shaped strips we put on.

FLAT-BOTTOMED FOUNDATION—SOMETHING IN ITS FAVOR.

During the honey-seasons of 1886 and 1887 I experimented in a small way with flat-bottomed foundation in supers. I have tested it in every way which my imagination could suggest, to see if I could discover whether the bees have any choice between that and that with natural base. When bees were storing honey moderately well, I have put on supers with sections filled alternately with flat-bottom and natural-base foundation; and on examina-

tion the next day it would all be drawn out so nearly equal that I could see no difference therein, and could tell which had the flat bottom only by the mark which I made upon the sections. Again, if very thin flat-bottomed foundation be put in the supers at a time when no honey is being stored, and this state of things continue for any considerable time, the bees will sometimes appear to nibble it off or cut it away. I think that they use the wax for capping other combs, while at the same time they will leave heavier foundation untouched. My limited experience inclines me to the conclusion that, when there is a good flow of honey, the thin flat-bottomed foundation will be accepted and appropriated by the bees without any hesitation; and if such are the facts, then there would be quite a saving for the apiarist to use the thin foundation; and, what is better still, the honey would contain more natural comb, and less of manufactured wax, which is so often compared to fishbone in honey.

Seymour, Wis.

JOSHUA BULL.

Thanks for the results of your experiments. We are glad to hear something in favor of flat-bottomed foundation, even if it is not of a very positive nature. We are inclined to think that, during a good flow of honey, the bees would show little difference in favor of either the flat-bottom or the natural-base foundation. We should be glad to hear from others who may have compared these two kinds of foundation.

REPORT FROM INDIANA.

The honey crop in this section of the State will be very light. There will be but little surplus. The whole season has been very poor. The spring opened with prospects fine, but it has been very dry nearly the whole season. White clover, though blooming well at first, seemed to produce but little honey. The hot sun seemed to check secretion. Basswood produced but little. Goldenrod is coming into bloom, but not a bee is to be seen on it. It is three weeks earlier than I ever saw it before. We have had over four weeks of steady and extremely warm weather, and the last two weeks hot. The thermometer has averaged above 86° the past week. It has reached every day 90 and above; several days 100 and above, up to 104. We have had two fine rains since the 4th of July, but the sun has come out so hot that it seemed to do vegetation but little good. Corn and potatoes are badly injured, and the ground is so dry that farmers can not plow for wheat. Bees have generally gathered enough to winter on. I don't think the honey market will be overstocked this season, and prices will be good.

A. D. STOCKING.

Cedar Beach, Ind., Aug. 2, 1887.

BEE BOTANY,

OR, HONEY-PLANTS TO BE NAMED.

VITIS BIPINNATA.

AS I have found one of the greatest honey-vines in the South, and can not find any one who can give me the name, I inclose you a small twig of the vine. It blooms from early spring until fall. Bees are booming on it now, and have been for over a month since I first discovered it. Please give the name. It is plenti-

ful in this country. It has ripe fruit and blossoms on it now.

F. M. DAVIDSON.

Collinsville, Ala., July 19, 1887.

[The plant you send us is *Vitis bipinnata*, T. and G. The botanists say nothing of its qualities as a honey-plant.]
Columbus, O., Aug. 2, 1887. Per Craig.

THE ROCKY-MOUNTAIN BEE-PLANT.

I am trying to find a name for the plant of which I inclose a specimen. Is it what is called the Rocky-Mountain bee-plant? As you see, it has a purple bloom; it grows about 18 inches high, sending out branches in every direction.

C. E. CARROLL.

Parma, Col., July 26, 1887.

The specimen of plant you send is the Rocky-Mountain bee-plant, as you suggest. You will find a full description of it in the A B C of Bee Culture.

REPORTS ENCOURAGING.

DEFEATED, BUT NOT DISCOURAGED.

BEES have done quite poorly this season. I had only one stand out of 30 that went into the supers. It made about 12 lbs. of marketable honey. I have one stand of hybrids which secured about 50 lbs. while many of the blacks did almost nothing, and are now in a starving condition. White clover commenced yielding honey on two occasions, but each time it was stopped by heavy rains. Basswood gave honey about two days. There is yet some prospect of a crop of fall honey, which will be most gratefully received. If my bees had all been Italians or hybrids, like the one mentioned above, I should have done quite well. I have heard of bees fighting and stinging the operator when a hive was opened (when robbers were troublesome). I have handled blacks for 4 years, and have now 35 stands, yet I have never had the experience mentioned. Are not blacks inferior to Italians in poor seasons, and equal in good ones?

N. J. FLINT.

Georgeville, Mo.

Friend F., do you mean to say that robbing in your apiary does not increase the danger of stings when you open a hive? The point is this: When there is a dearth of honey, and the bees find nothing in the fields, they hang about the hives or in the honey-house. If every thing is kept out of their reach, however, little harm is done; but let them get a notion that honey may be stolen from neighboring hives a hundred times faster than they can get it from the fields, and bees, like human beings, begin to develop bad and vicious tempers; and after this thing has got well started, we have more trouble with stings than we ever had before. In fact, it not only troubles the proprietor, but his neighbors, and the teams in the street, if he does not take prompt measures to stop it. My impression is, that the trouble with bees in or near towns or cities has pretty much all come about by this sort of carelessness. I have not had much experience with black bees in this line, of late years; but I never noticed that they were very much different from Italians. I do know, however, that hybrids are ever so much worse than either race pure, when

robbing and stinging get to be the order of the day.

OVER ONE TON OF HONEY.

The season came to a close very suddenly. The honey crop was light in this county. I shall have something over one ton, almost all box.

Romulus, N. Y., Aug. 8, 1887.

J. F. HUNT.

ENOUGH TO WINTER ON.

Our bees gathered about enough in one week to winter on. They stored it above, and it was taken as surplus. The prospect is now that I shall feed as much as I have taken. There is, therefore, now really no surplus. I have some hopes yet from red clover and aster.

S. W. MORRISON.

Oxford, Pa., Aug. 9, 1887.

RECEIVED \$500 FOR A LAST YEAR'S CROP.

It is getting rather late to send in my report for 1886, but better late than never. I have just got through disposing of my last year's crop. I had 3335 lbs. of white-clover honey, for which I received 12½ cts. per lb., amounting to \$405.95. Then I had nearly 700 lbs. of very dark honey, which I sold for 5 cts. per box. I also had 500 or 600 lbs. of extracted. We ate of it gave some away, and what I sold brought me \$37.00. Altogether I received between \$490 and \$500 for my crop. I started in the spring with 51 colonies, increased to 68. J. A. KENNEDY.

Farmingdale, Ill., June 13, 1887.

REPORTS DISCOURAGING.

"NOT MUCH HONEY."

I FIND, in looking over my bees, that there are some colonies that have not got honey enough to winter on. The weather has been so very dry all summer that bees in this part of the State have done nothing. One gentleman living not far from this city ran his apiary of 40 colonies for comb honey, and said he did not get a pound. Another, of about one hundred colonies, ran half for comb the other half for extracted, and got only about 300 lbs. of extracted, so you see it is considerably discouraging. A gentleman living eight miles from here ran 40 colonies for comb honey, and got about 1000 pounds. He uses the Simplicity hive, but took out three brood-frames and put wide frames on the side with sections in. The side storing seems to be good. A. E. SMITH.

Darlington, Wis., Aug. 12, 1887.

BEES STARVING.

Bees are starving as fast as time rolls around. I came from Texas a few days ago and found half my bees starved out. I am feeding the others. It has been the driest time since 1881. Grass, weeds, corn, and all are burning up. There is a good prospect to-night for a rain. If we should have such, bees would store winter food from Spanish needle yet. If this is not discouraging I hope such a time won't come.

W. W. ADDISON.

Bumpus, Ill., Aug. 11, 1887.

HALF A CROP.

The honey-crop in this section is less than half. It is very dry. Honey is moving moderately at 14 and 15 cents. The market is getting firmer. It gives us more light in regard to the kind of foundation to be used in sections. Poorly drawn founda-

tion, with some honey on each side, is not very tempting to the consumer's appetite, and I have good reason to believe that there is much such goods that goes on to the market, and I am afraid of the consequences.

A. A. HARRISON.

McLane, Pa., Aug. 15, 1887.

HONEYED VISIONS GONE; IS IT FOUL BROOD?

I "swarmed out" with a new "queen" on March 20, and have been very busy since, fixing up. You have been asking, through GLEANINGS, for "Reports Discouraging." While I myself am not discouraged, and still less ready for "Blasted Hopes," my report for this spring, and the prospects for this summer, certainly present a discouraging front. All my sweet hopes and honeyed visions have been taken themselves to ignominious flight, leaving my pocket-book under the elephant's foot. I went into winter quarters with 10 full colonies, 2 five-frame, and 3 four-frame colonies. One colony was in a two-story Root chaff hive; the remaining 14 were in Simplicities, with chaff on top and sides; and notwithstanding a severe winter they came through in good condition. All were rearing brood nicely when fruit-bloom commenced (about the 15th of April). In the midst of fruit-bloom we had a week of wet weather which put them almost on the starvation-point. It checked breeding to some extent, and caused them to kill their young drones.

About the first of May I purchased 4 more colonies, making me 19 in all. In the latter part of April and the first part of May I moved them about 1½ miles; when I moved the second lot I examined them (May 3) to see if any combs were broken down, and was astonished to find 3 colonies with diseased brood. The symptoms did not, nor do they yet, tally with those given in the A B C and in various numbers of GLEANINGS, of foul brood. A friend told me he had a colony similarly affected last year, which he cured by introducing a new queen; so I thought I would try that. I gave them capped queen-cells. The queens are not yet laying. A few days ago I found three more colonies in different parts of the yard taking the same disease, so I determined to try Prof. McLain's remedy, given on page 697, GLEANINGS, 1886, except that I could not extract the honey, which is hardly necessary, since the most of my colonies have very little honey (white clover is a failure). The peculiarity of the disease is, that about three-fourths of the brood dies just before it is ready to cap over. Very little dies after it is sealed. The greater part of the affected larvae shrink, just as if something had sucked their juices, and finally dry up entirely; now and then one turns to a brownish-looking mess. This seems to be the case only with those that die about the seventh day from hatching. There are no sunken cappings nor pinholes. Of course, there is an unnatural smell about the hive, but not what that from true foul brood is, judging by the descriptions in A B C and GLEANINGS. A. L. HEIM.

Chandler, Ind.

From the facts you relate, I should rather judge the disease you found among your bees was foul brood. You know, I presume, there is one phase of it where the brood dies before being capped. However, in our experience we never noticed unsealed dead brood without finding some in cells capped over. I think, if you were to rake over the cells of capped brood, where you find the

unsealed diseased brood you would be pretty sure to find diseased brood. You did not say whether you were successful in treating foul brood by McLain's method.

OUR QUESTION-BOX.

With Replies from our best Authorities on Bees.

All queries sent in for this department should be briefly stated, and free from any possible ambiguity. The question or questions should be written upon a separate slip of paper, and marked, "For Our Question-Box."

When Should we go to work to Raise the Best Queens?

Question No. 1. If the bees supersede their queen in the fall or spring, is such queen as good as one raised in the swarming season? M. E. W.

Yes. DADANT & SON.

Yes. PAUL L. VIALLO.

Not with me. DR. A. B. MASON.

Yes. I think they are, providing there is a good strong colony of bees at the time. E. FRANCE.

I have but few queens superseded. Their successors, even when raised in the spring or fall, have shown no signs of inferiority. W. Z. HUTCHINSON.

If raised in a strong colony, the old queen being present till the young one is raised, I think the difference, if any, is slight. C. C. MILLER.

Theoretically, no; yet I have had queens superseded in the interims of the honey-harvest which were among the best I have ever had or seen. A. J. COOK.

Yes, providing the old queen keeps laying or stays in the hive till the queen-cells are capped over. If the supersede comes from the death of the old queen, no. G. M. DOOLITTLE.

Yes. Mr. Langstroth said at Detroit, that he had noticed, when bees superseded their queen, that it invariably proved to be a good one. They are dissatisfied with their queen, and undertake to rear a better one, and do it. MRS. L. HARRISON.

Under certain circumstances, such a queen might be good, and no doubt as good as many of the queens raised in the swarming season; but as a rule, governed by natural principles, such a queen will not be as good as one raised in the swarming season. JAMES HEDDON.

I have watched this point closely for a number of years, and have been able to detect no difference, unless it was that such queens are not usually as long lived as others. O. O. POPPLETON.

It would be well if we had more positive data than seem to exist at present as to the value of queens reared out of season. In default of this it will help some for bee-men to give their impressions, as I proceed to do.

1. Queens reared too early are worthless for lack of fertilization.

2. Queens reared late enough to be fertilized will average a little below, but not very much below, queens reared under the swarming impulse.

3. Queens reared after swarming is over are liable to be quite inferior, but not certain to be so.

E. E. HASTY.

It seems to me, friends, there is one point in the above that you have not touched upon. It is this: Some colonies, as you know, will rear an extra queen to work side by side with her mother; and as fast as these extra queens are taken away they will rear more. At different times, when this subject has been up, the importance of developing this trait has been mentioned. Now, these queens, no matter when they are reared (providing, of course, the weather is warm and the bees are getting pollen and honey), are among the best and longest lived we have had. Have you not found it so?

How many Pounds per Colony do our Best Bee-keepers get, on an Average?

Question No. 2. What do you consider an average yield of honey per colony (mention whether comb or extracted) in your locality? S. J. M.

Extracted, 50 lbs.; comb, 25 lbs.

DADANT & SON.

Sixty lbs. of extracted. DR. A. B. MASON.

100 to 125 lbs. extracted; 75 to 100 lbs. comb honey.

PAUL L. VIALLO.

Fifty lbs. of comb; 80 of extracted.

W. Z. HUTCHINSON.

Fifty lbs., spring count, taking an average of several years. I have had little experience with extracted honey. MRS. L. HARRISON.

About 75 lbs. of extracted, or 50 lbs. of comb honey, and an increase of nearly 100 per cent, would perhaps be about an average in all the years I have kept bees here. JAMES HEDDON.

My own average for over a dozen years past in Northern Iowa was 110 lbs. per colony of extracted honey. My experience is too small in this locality to give any estimate. O. O. POPPLETON.

According to my records for the past 12 years, my bees in different parts of this, Ventura Co. (Cal.), have yielded me about 85 lbs. per hive annually, spring count, all extracted honey. I suppose mine will about average with others of the county. R. WILKIN.

My average yield has been not far from 75 lbs. comb honey, and 150 lbs. extracted, according as worked for, each year for the past 14 years, a larger average yield for the first 7 years than the last 7. G. M. DOOLITTLE.

In estimating 50 lbs. comb and 75 extracted, I should think I was quite low. I have taken 100 lbs. of comb several years in succession; but a few such years as the present will bring it away down. A. J. COOK.

For 18 years the average yield has been 39½ lbs. comb honey. Greatest yield per colony in any one year, 117 lbs.; least, 0. With good management and no overstocking, I think the average might be 50. C. C. MILLER.

We have run for extracted honey for several years past. Taking the years 1883, '84, '85, and '86—four years in succession—our average was 103 lbs. per colony, spring count. But this year our yield was only 50 1/2 lbs., or about 12 lbs. per colony, as we had 415 colonies, and we are not sure but we shall have to feed back all we got, if not more, to winter

the bees. See GLEANINGS, page 976, 1886; also this issue, page 655.

E. FRANCE.

My locality is a very poor one, and the average yield of section honey is less than 20 lbs. To partly balance this, the spread of fall flowers and the supply of spring pollen are so large that it seems to make little difference how many colonies are kept. Even in very bad seasons there is pretty sure to be some surplus; and with the yield as low as 10 lbs. per colony one can get quite a pile of honey *if he keeps colonies enough*. It is a live man's business to see just where his main chance is, in his own location and circumstances, and go in on it.

E. E. HASTY.

Many thanks, friends, for the care which you have given these reports. It did not occur to me before, that any thing of so much value could be put into so small space. I was especially pleased to see our jolly friend C. C. Miller put in that 39½ lbs. I can imagine a mischievous smile twinkling on his countenance when he put in that *half-pound*. Old fellow, why didn't you say 40 lbs., when you came so near it? I suppose you have heard of the witness who, when asked how far he stood from the parties who were fighting, replied, "Just 17 feet 9 inches." When asked how he came to be so accurate, he said he expected some lawyer or other blundering fool would ask the question, and so he took his rule out of his pocket and measured the distance exactly. Now, friend M., I don't mean to say that of you, but I feel glad that you sat down and took time and pains to tell us exactly what we have a right to expect, without any guesswork about it.

How many Pounds per Colony have been Secured by our Experts, and how much does Overstocking Affect these Results?

Question No. 3.—What is the largest yield (comb or extracted) you have ever known in your locality, from a single colony? In your judgment, what is the largest number of colonies that could have been kept in that one place, that season, without diminishing the yield of that one colony? M.

Two hundred and fifty pounds of extracted. Ten.

DR. A. B. MASON.

1. 195 lbs. comb. 2. Perhaps 80. C. C. MILLER.

1. About 450 lbs. extracted. 2. About 100 colonies. DADANT & SON.

A single colony, spring count, 200 lbs. The old colony, 120 lbs., and its swarm, 80 lbs.

MRS. L. HARRISON.

First, 309 lbs. comb. Second, 566 lbs. extracted. Third, 150 colonies. The above yields were taken by myself in 1877.

G. M. DOOLITTLE.

1. 302 lbs. The average of all was nearly 200 lbs., and I think that, if there had been 500 colonies, the yield would have been as much. It was the best season I ever had.

PAUL L. VIALLO.

To the first part of your question I will answer, 410 lbs., 48 of which were comb, the rest being extracted honey. The latter part of your question relating to overstocking is one that has puzzled me much, and on which my 18 years of bee-keeping, most of which has been on an extended scale, does not warrant me in attempting to answer.

JAMES HEDDON.

In 1887 my bees, 416 hives, at Sespe Apiary, yielded me an average of 185 lbs. extracted. There were about 1000 colonies besides these, within two miles of mine. Localities where only a few were kept yielded perhaps one-fourth more. We rarely keep an account of the yield of a single hive here.

R. WILKIN.

In 1886 we had 12 colonies that averaged 164 lbs. There were 61 colonies in that apiary. I never saw a location yet where I would believe 100 colonies could store as large an average yield of honey as would a less number. We keep from 60 to 80 colonies in a place. I think that enough for profit.

E. FRANCE.

I have never kept the honey of each colony by itself with sufficient exactness to answer the query. The year 1886 was the best season I ever had, when 50 colonies stored 6800 lbs. of comb honey and 200 lbs. extracted. I think 100 colonies might have been kept without lowering the yield *pro rata* very much.

W. Z. HUTCHINSON.

I can not say. The largest net return I ever knew from a single colony was \$70. On several occasions our bees have netted us \$20 or over, per colony. I should prefer not to have more than 100 colonies at one place, though on certain years I believe more could be kept with no loss.

A. J. COOK.

I worked my apiary as a whole, and not as so many single colonies, and know but little about yields from single colonies. The largest amount of extracted I know of getting from one colony was 275 lbs., and from another 160 of comb. Any answer to the second part of the question would be pure speculation.

O. O. POPPLETON.

My own best yield is 142 lbs. of sections from a colony and its increase. I can not at this moment tell if my immediate neighbors have surpassed it or not. Very likely one colony more would have decreased the yield *some*; but I do not think that a hundred more would have decreased it more than one-fourth. I agree with the prevalent opinion about overstocking as to most locations, but my location is peculiar (see last answer). In working on basswood also, my bees have to go four or five miles to reach it; and when they get there, there is a good deal of it; so the number of colonies does not seem to signify much.

E. E. HASTY.

These answers seem to indicate that but little is known positively in regard to this vexed question of overstocking. I can imagine just how Dr. Mason straightened up his portly form when he brought his fist down, and declared that not more than ten colonies could have been kept in the yard with the one that gave 250 lbs. in one season, without affecting the result, and I am inclined to agree with you generally. We have had so many large reports from small apiaries—that is, large compared with the reports per colony from large apiaries—that I do believe a small apiary will, as a rule, give the best results; but the question then arises, Will it not pay us better to keep 100 colonies, even with a much smaller average per colony, than to have our bees located in so many different places? I don't believe, however, that it is best to increase to such an extent that we get down so low as 10 lbs. per colony on the average, as friend Hasty puts it.

MYSELF AND MY NEIGHBORS.

Why beholdest thou the mote that is in thy brother's eye, but considerest not the beam that is in thine own eye?—MATT. 7:3.

WHEN do we see our neighbors' faults so plainly and so easily, while it is with so much difficulty that we can be made to see and comprehend our own? I have just been thinking of one reason for this state of affairs. There are several reasons, but I am pretty sure this one is an important factor. It comes in something this way: The world says, "Every man should first look out for number one." The Bible says, "Not so. Thou shalt love thy neighbor as thyself." The world says, "Look upon every man as a thief until he has proved himself to be an honest man." The Bible says to this, as I understand it, "Not so; but, rather, look upon every man as an honest man until he has proved himself to be a thief." Now, when I say this I also say, but by no means intrust even an honest man with a large amount of property in a reckless way. Even while you recognize that your neighbor is as good a man as yourself, you are not to be in haste to place temptation in his way. Many of the troubles and jangles that come about among the bee-friends are because things are left loosely. Business is done in a sort of heedless and careless way. One man sends on a lot of honey or beeswax, and does not even know how much he has sent. Now, friends, it seems to me you have no right to do things in this way, no matter whom you are dealing with. If you want to feel kind and charitable toward your neighbors, keep things straight as you go along. Instead of trying to remember the particulars of a transaction, write it down in white and black. If you keep bees on shares, have a clear understanding as to how it is to be done, and write it down and have both parties sign the paper, but don't either of you sign it without reading it through carefully. Having done this, abide by the paper, no matter who loses or gains. If you want to have confidence in your neighbors, keep business close and snug. If you are intrusting work to others whom you have employed to work for you, keep an eye on them. If you want the work well done, make arrangements so you can look after it often, then see whether your hired help understands exactly what your wishes are. Many people lose their confidence in their neighbors and in their fellow-men, because of their own heedlessness in this respect.

Friend Terry, in his potato-book, expresses strong doubts as to whether artificial fertilizers are of any value to the average farmer. I think very likely he carries the matter to extremes; but of this I am sure: That a great many pay out money for fertilizers when it does them no good whatever. What, then, are we to do? The agricultural papers of late are recommending that each farmer shall test fertilizers on his own grounds; that is, don't get enthusiastic, and take it for granted that because others have done well by the use of phosphates you can do well also. A good many, the first time

they try phosphate or bone dust, in their zeal will put on double the usual quantity. They take it for granted, that if a little is good more is better. Now, it is a very difficult matter indeed to be able to say positively what it was that gave you a crop. If you occasionally withhold the fertilizers from a strip of ground right through your lot, this affords pretty good evidence. In my earlier experiments with guano I killed so many of my choice plants that I began to wonder whether guano possessed any value at all or not. I became so disgusted with it, in fact, that the bag was allowed to stand in the greenhouse, without being used at all. Finally we had some celery-plants in boxes, that stood so long before being transplanted they began to look yellow and as if half starved. Watering them repeatedly did little or no good, for so many waterings had washed all of the fertilizing material out of the dirt contained in the shallow boxes. One of the boys suggested sprinkling a little guano among the plants before they were watered. It acted like a charm. The plants started up with vigor. The foliage became dark green, and the growth rank. A teaspoonful of guano to one of the boxes helped them wonderfully; but a handful might have killed them all. Now, my friends, while you have faith in God and faith in humanity, and feel anxious to do something for Christ and something to help your fellow-men, you might commence exactly as we commenced with guano. If a friend of yours is in straitened circumstances, and needs a little assistance, be careful about overdoing the business. Giving him so much help all at once may work as much mischief as the guano would if put on the strawberry-plants. Look into his circumstances carefully, and give him a little assistance at first; then watch and see how it works. If good comes of it, help him a little more in the same way, and so on with all your deal and intercourse with humanity. This is reason and judgment. Don't be in haste to do some big thing.

Last evening a missionary just returned from Africa made a remark something like this: A man who is doing mission work at home will probably do successful work in Africa. If he is not bringing souls to Christ in his own neighborhood, he will rarely succeed in doing so in Africa. If you want to be a missionary, commence right where you are, commence with little things. When you succeed with the neighbors you have, with commonplace individuals, you will probably succeed in a wider field; but don't start out in a wider field all at once.

I have just been pained by a letter from a younger brother of mine. He is trying to be a Christian, and trying to be a good member of society; but he has troubles and trials and tribulations beyond those common to most men. Why is it, he says, that when I am trying to do right, I get deceived and wronged at almost every turn? The trouble is, my friends, he is trying to do too much. He owns a large farm close to a growing city; but instead of staying at home, and keeping an eye on every acre of that farm, he has two or three times tried

starting business in town. He intrusted his stock, buildings, and land, to hired tenants. First, he didn't get any rent. The next time, he let his land out on shares. The result was, that two or three of his horses were worked to death, and other things managed in much the same way. He trusted too much to humanity in one way, because he didn't have his business under his personal supervision. I am afraid he rushes to the conclusion that these people are all bad and selfish and evil. I presume, dear friends, they are no worse than the neighbors you have right around you, or, to come still closer home, no worse than you or I. May be they hadn't sound judgment to undertake the management of a large farm, and ought not to have been trusted in this way. When you have faith in the good intentions of your neighbors, remember they are frail and human. Thus without having any hard feelings toward them particularly, you may remember they are selfish. Many a good steady hard-working man has been made to show to a great disadvantage simply because he has been pushed into some place he was not competent to fill. Some people do not seem capable of having money in their possession without paying it out foolishly. Now, I don't believe it is right to call such people thieves because they pay out money that does not belong to them. I have known quite a number who seemed to be honest and upright and straight in every particular until some money or property was injudiciously put in their hands for safe keeping. At first sight one would be tempted to think that they yielded to temptation; but a more careful investigation seemed to indicate there was no particular temptation about it. They simply let the money slip without being hardly aware they were responsible for it. Had they been tried first with a very little money or a very little property, to give them a little practice in the way of assuming responsibility, they would probably have turned out all right. But it was like the guano in my experiments with strawberries. They hadn't even been educated up to the point of bearing responsibility by careful tests on a small scale. Now, dear friends, I want you to think kindly of those about you; I want you to think kindly of all your neighbors—even the bad ones. I want you to think kindly of the criminals in your county jail; and if the suggestions I have thrown out in this paper shall be the means of causing you to inquire whether the bad state of affairs is not owing a great deal to injudicious acts such as I have mentioned, I shall have accomplished my purpose.

A poor unfortunate fellow-being is now confined in our county jail for attempting a crime that makes all good men and women shudder. In fact, a mob gathered round him and might have taken his life had he not been rescued by the proper authorities. The man is a laborer in a neighboring stone-quarry. During a kindly talk with him I felt pretty well convinced that he was nothing but a commonplace individual, not particularly worse nor better than thousands of others. I did not notice any thing vicious

about him, nor any signs that he was lost to good feelings and good impulses. A slight stoppage in their work at the quarry induced him and some of his fellow-laborers to take a holiday at a beautiful lake near the center of our county. This lake is quite a fashionable pleasure-resort; but, alas! a beer-saloon disfigures its grounds. This man is a foreigner by birth, and, of course, he must have some beer. Very likely something besides beer crazed his brain and inflamed his passions; but for God's sake, friends, don't be in haste to conclude that such or such a one is absolutely bad. Don't be in a hurry to say that the best place for him is inside of the penitentiary walls; and don't be so hasty in your condemnation as to say the mob ought to have killed him under the circumstances. Christ died for even such as he. I would not save him from the penitentiary: I think he ought to go; and I suppose it is best to let the law take its course, even where these feeble-minded people are so thoughtless as to use money which they have no right to use. But does it not behoove us all, especially those of us who are followers of Christ, to be careful how our careless or heedless acts make our friends and neighbors stand to bad advantage before the world? Be sure, dear friends, there is not a beam in thine own eye before you undertake to pluck out the mote from thy brother's eye.

TAILOR BEES, ETC.

PROF. COOK TELLS US SOMETHING ABOUT DIFFERENT MEMBERS OF THE BEE AND WASP FAMILY.

WE received from John Linersridge, Anguilla, Sharkey Co., Miss., a lot of bits of leaves, cut up in round circles, done up in brown paper. He said he found it in one corner of a hive, but did not know what to call it. We recognized it as the work of the tailor bees, as has been often mentioned in our journals; but as there was quite a quantity of circular leaves made concave, or cup-shaped, and nested into each other in this nest, we forwarded it to Prof. Cook who replies:

Editor Gleanings:

These are the curious cells of the interesting "tailor" bees—*Megachile* (see Manual, p. 28). These bees cut regular pieces—circular or oblong—from rose and other leaves, and by ingeniously fastening them together they form these hollow cylinders, which are stored with food, and then each is stocked with an egg. Often there are many such cells placed end to end at one place. I know a lady who left her knitting-work alone for a time, and upon taking it up found several of these cells within its folds. I have often found them in grass. The cells are about one inch long, and one-third of an inch in diameter. The bees are about the size of a common honey-bee, which they somewhat resemble. They may be told, however, by the bright shining yellow hair on the under side of their abdomens, and also by the curious way in which they raise this part of their body as they walk over the flowers. These yellow hairs are used to gather pollen, and such bees will be seen, oftentimes, with these hairs fairly loaded with the golden pollen-dust.

THE DIGGER-WASP.

The large wasp sent by one of your customers—you did not mention the locality, for which I am sorry—is the handsome "digger" wasp, *Stizus speciosus*. I have received it from Kentucky, Tennessee, Southern Indiana, and Southern Illinois. There is another, still larger, found in the Southern States—*Stizus grandis*. These wasps are black, or dark-colored, marked with handsome yellow spots on the abdomen. The thorax is brown.

This one sent has been known before to capture the cicada—usually, but incorrectly, called locust. I presume the insect captured in this case was a cicada, or harvest-fly. The true locusts are grasshoppers, and so, of course, belong to quite another order of insects. These wasps are called digger wasps, as they dig holes in the earth, where they place their prey, after which they lay an egg in the captured insect, when they proceed to cover all with earth. A still more interesting fact is yet to be told. The wasp is armed with a powerful sting. By aid of this she is able to paralyze large insects like our largest spiders, *cicada*, etc. Thus the prey of these wasps is simply stunned, and not killed, and so the young of the wasp, when the egg hatches, has right at its command fresh tender insect-steak, and has only to eat and grow fat. I doubt if these wasps ever do apiarists any serious harm. They are not sufficiently common. In Europe, however, similar wasps are a serious annoyance to bee-keepers.

A. J. COOK.

Agricultural College, Mich.

You have before told us something about this wasp that has the knack of putting away his fresh meat so it does not spoil—that is, paralyzing them by stinging so the victim will keep many days or even weeks in a state neither dead nor alive. Perhaps we might call it hibernation, only they never come out of it. Now, here is an interesting question for naturalists: How long may these insects be kept in this comatose state, induced by the stinging of this peculiar wasp?

A NAP BEFORE DINNER.

MRS. L. HARRISON GIVES US HER EXPERIENCE IN REGARD TO THE MATTER.

BRO. ROOT:—I've always thought you had a mistaken idea with reference to work—"clear over the horse" on that subject, and isn't that the cause why you are suffering with nervous prostration? Is there any reason why a person should toil from early morn till dewy eve, without any rest? I know women who always have "catch-up" work, and never allow themselves an idle moment; but the major part of them are nervous, and very fretful and unhappy at times. My mother worked every wakeful moment, and taught me to do the same; but when I saw her old at fifty, and in her grave twenty years before her brothers her seniors, I made up my mind that henceforth I would rest when tired. I have arisen at five in the morning, and worked very hard until eleven, and then left off and had a nap and an hour's rest before I ate my dinner; then I was able to do another half-day's work. If I could not get this rest I was good for nothing the rest of the day. An after-dinner nap didn't refresh me as the former. I've always thought that that hour's rest was worth more to my family than any other. Since

I've been keeping bees, I can not command this rest-hour, as the bees will not respect it at all; but I make up for it, as well as I can, by retiring earlier.

Bro. Root, when you are irritable and cross, don't attribute it to the "Evil One," but see if your stomach, liver, and nerves are not more to blame than this active gentleman. He may be entirely innocent of the charge.

MRS. L. HARRISON.

Peoria, Ill.

Well, I am really glad, sister H., to have your testimony in regard to my new hobby of doctoring without medicine; that is, doctoring some complaints without medicine; and I am glad to hear you say that the after-dinner nap did not answer. You are partly right, no doubt, in your closing remarks; that is, the part of our bodies intended to digest our food, and send the results of it into the proper channels, must have time and elbow-room to do its work. Digestion can not go on in a natural way when we feel as if a breath of wind would blow us over. I believe, however, that the Evil One is always watching his best chances. The Bible says, you know, that he is constantly going about like a roaring lion, seeking whom he may devour. Well, when we are so foolish as to overtax our strength and energies, Satan is always at hand; but a good Christian—one who has faith, and is rooted and grounded in Christ Jesus—should be able to say, "Get thee behind me, Satan," even at such times. By all means, fortify yourself physically against disease and all the consequences that follow, and at the same time be sure your feet are always planted on that Rock that stands, though heaven and earth should pass away. I am glad to hear you say that you more than make up for the hour or half-hour that might seem to be lost.

TOBACCO COLUMN.

SMOKERS FOR TOBACCO-USERS WHO ARE NOT SUBSCRIBERS TO GLEANINGS.

IF your offer of a smoker extends to non-subscribers, you may send me one. I have just quit smoking, after using it more or less for fifteen years; and if I use it again I will pay you for the smoker. I think I shall be as well off, both temporally and spiritually, without it.

New Lyme, O., July 21, 1887. J. N. RICHMOND.

Friend R., when we first proposed giving a smoker to any one of our subscribers who would give up tobacco, we had no thought of extending the offer to any but our subscribers, or, if you choose, to the GLEANINGS family; that is, those who read and contribute to the support of the journal. And by the way, friend R., I hope you will excuse me for saying that it seems to me that any one who proposes to take advantage of this liberal offer should be willing to subscribe for the journal making the offer. Recollect, there is no pecuniary profit in giving a smoker to those who give up using tobacco. We give you the smoker simply for your own good, or, if you choose, to encourage you in right doing, and with the understanding that you save money instead of losing money by accepting our little gift.

Now, taking it in that light, would you have the heart to ask us to give you this implement outright, when you don't care enough for our journal to subscribe for it? Aside from this, there is another point involved: He who receives a smoker for giving up tobacco expects to have his name appended to his promise to abstain; and this promise, with the signature, is to be printed in GLEANINGS. He himself reads this promise in GLEANINGS, and his friends all read it; and if he is ever tempted to break his pledge we hope and expect that somebody who reads GLEANINGS will remind him of the broken promise. But if he is not a subscriber to GLEANINGS, how shall anybody know of the public contract and agreement he has entered into? I think, my friend, your own good and your own safety depend upon your being a subscriber. There is one case, however, under which we think best to deviate from the above rule. Where any subscriber to GLEANINGS writes us that he will pay for the smoker if the friend breaks his pledge, this answers every purpose; and, in fact, I rather prefer to give them away in that manner: for the subscriber who is sufficiently interested to get pledges in this way will be quite certain to watch over his weak friend, and straighten him up if he shows symptoms of wanting to slip out of his contract; for almost any man, woman, or child, would rather pay the small amount of 70 cents than to have it said he had broken a promise given in print over his own signature.

I will pay for the smoker sent if I break my promise which I hereby make. T. H. VAIL.
Evans Center, Erie Co., N. Y.

I have quit the use of tobacco. If I use it any more I will pay you for the smoker.

F. M. THORNTON.

Hartwell, Hart Co., Ga., July 1, 1887.

I have quit the use of tobacco, and will never use it again. Please send me a smoker. If I ever use the weed again I will pay for the smoker.

Alburgh Springs, Vt. W. A. CRELLER.

By the grace of God I will quit the use of tobacco. If you will send me a smoker, if I ever use tobacco again I will pay for the smoker. May the good work go on! G. H. REED.

Anneville, Tex.

My friend Henry McClarin has quit using tobacco, and is working for me. Send a smoker; and if he uses tobacco again I will pay for the smoker.

D. C. UNDERHILL.

Manatee, Fla., June 24, 1887.

We received the smokers the 1st inst., and I was truly surprised at such a nice smoker. I have not only quit smoking and chewing, but have resolved never to taste a drop of that poison, liquor.

Kenton, O., Aug. 3, 1887. C. L. MOORE.

I do not use tobacco, and do what I can to dissuade others from using it. Mr. Rolan Routen, a neighbor of ours, and once a slave to tobacco, has quit, and says send him a smoker. If he ever uses it again he will pay you for the smoker, and I will see that he does.

R. F. CARTER.

Henry, Tenn., July 19, 1887.

I have quit the use of tobacco, and am trying to raise bees; but so far I have been very unsuccessful. I think perhaps by the aid of your smoker I could be more successful. If I begin the use of tobacco I will pay you for it.

W. W. RAMSEY.

Ashbeysburg, Ky., July 20, 1887.

I have been a moderate smoker for about two years; and if it is not imposing on your generosity you can send me a smoker. Send one also to a beginner in bee-business, by the name of Frank Schlingloof; and if either one of us commences again, I agree to pay you for both of them.

Kenton, O., July 26, 1887.

C. D. MOORE.

Please send a smoker to Mr. Lee Clow, Ozan, Hempstead Co., Ark., for he has quit the use of tobacco, and he says he will take the pledge. He has been a slave to its use for 25 years; he is now 54 years old, and he says he will pay for the smoker if he uses the weed again.

J. W. TAYLOR.

Ozan, Ark., July 26, 1887.

I notice that you propose to give a smoker to any one who will agree to quit the use of tobacco, and to pay for the smoker should he use it again. At the solicitation of my wife, I will take a smoker on those conditions; and should I begin the use of tobacco again I will remit you the price of the smoker promptly.

J. A. DANIEL.

Rockport, Aransas Co., Texas.

I have been using tobacco, both chewing and smoking, for 22 years. For the last sixteen years I have been keeping bees, and always used tobacco-smoke about the hives; but now you make war upon the weed, so I will quit. But as you seem to be interested in this matter, making a "hobby" of it, as it were, I shall be pleased to let you have your own way; so please send along the smoker, by mail; and if I ever give up and take to the use of the filthy weed I will pay you for two smokers.

M. A. KELLEY.

Milton, Cabell Co., W. Va., July 26, 1887.

I commenced using tobacco at the age of 15, and have ever since until about 6 or 8 months ago when my health failed and I decided to quit, and have succeeded so far. Will you send me a smoker? I promise you I will pay for it if I ever use tobacco again. We are having a very poor season here. I have taken only 12 lbs. of honey, and the bees are not storing any at present. I have 18 colonies to date. We have just had a few good showers of rain, and the buckwheat will soon be up. We seldom get any thing but fall honey.

F. J. DAHN.

Sturgis, Mich., July 6, 1887.

My uncle, Mr. F. S. Meuer, has only four stands of bees, all in Simplicity hives. They are doing well. He was in Bastrop about two months ago, and transferred a swarm, that was in a common box hive, into a Simplicity hive, for my other uncle, Mr. P. S. Rolfeigh. He is well pleased with his new stand now. Uncle showed him a copy of GLEANINGS, and he read it through. He was well pleased with the Tobacco Column, and he has quit using tobacco since he read it. If you think he is worthy of a smoker, please send it to him. If he ever uses tobacco again he will pay you for the smoker, and will also send two dollars and a half extra.

F. A. BURGIN.

Monroe, La., July 8, 1887.

A GOOD PLEDGE TO TAKE.

I have been looking over the Tobacco Column in GLEANINGS, and thought that something like this would look better:

"Dear Sir:—I have left off the filthy habit of smoking and chewing tobacco, and am saving about two dollars a month by so doing. Inclosed is that amount, the savings of the last month, and I want one of the best smokers made for that price. I not only save my money, but my wife says it does not make her sick every time I come into the house. If I ever commence the use of the weed again I hope that I shall have to handle cross hybrid bees without a smoker. I am giving the amount I formerly spent for tobacco to my wife, and she will soon have enough money to buy the best silk dress in town. L. C. WHITNEY."

Thanks, friend W. Your pledge is a capital one. By all means give the tobacco money to her who has been so faithful. Where is the good wife who will not make it go further than it formerly did? We should like to have some of the old tobacco-users, who have quit for a year or more, tell how much they have saved since—whether they are any better physically and morally. On the other hand, if any man is sorry he tried to give up tobacco, and afterward resumed its use, we should be glad to hear from him likewise, and his reasons for so doing. This column is open.

OUR OWN APIARY.

CONDUCTED BY ERNEST R. ROOT.

FOUL BROOD.

I SAID in the last issue I would have something further in reference to carbolic acid as a bactericide for the germs of foul brood. Recent developments, however, have been such that I deem it unwise to say any thing further. In the mean time we shall continue experimenting, and when we have arrived at something definite we will report. Perhaps it would be well to remark that we have secured the services of Mr. E. H. Sargent, a graduate of the course in Natural History of Cornell University. Mr. S. was one of my old chums and classmates. He has had considerable experience with bees; and when I told him about our experience with foul brood he became at once interested. He is familiar with the growths, such as are found in diseases like cholera, yellow fever, and certain others. Having a little leisure time before going back to take a post-graduate course in the University, I asked him to try what he could do in cultivating foul-brood germs in gelatine. He has done so, and has met with apparent success. In due time he will send in written reports from the University, where he will continue his experiments. After he has succeeded in getting what he *knows* to be the real germs of foul brood, beyond any possibility of doubt, growing in beef gelatine, he is then to experiment, with the view of determining what agencies, whether dilute or not, will utterly kill the growth. If carbolic acid or absolute phenol will kill it, what dilution is necessary?

Mr. Sargent will have access to all the apparatus of the University. He will also have the advice and assistance of one or more of the professors. I am sure that a number of our readers will await the results of his experiments in this line, with considerable interest.

OTHER USES OF CARBOLIC ACID.

While experimenting, for the purpose of disinfecting diseased hives and combs, I have found that carbolic acid, when diluted to not more than 200 times, makes a very good apifuge—that is, the bees flee from it. One day a swarm came out and persisted, in spite of all our efforts, in clustering upon one particular limb, inconveniently situated. Again and again we shook the limb, and succeeded in getting a portion of the bees, at least, to cluster on the comb which we held before them. The other portion still directed their flight toward the aforesaid limb. Knowing that bees have a great aversion for carbolic acid we sprayed some of it, diluted 200 times, on the limb. Every bee, as he approached the much-sought-for place of clustering, on discovering it had a very perceptible as well as disagreeable odor, departed in evident disgust. Shortly afterward, however, we had the bees clustering just where we wanted them to cluster: i. e., on the comb. During swarming times the apiarist will find carbolic acid, at a dilution of 200 times, quite convenient.

Something over a month ago the robbers had a little taste of honey while one of the boys was working over one of the hives. After he had closed the hive there was quite a swarm of robbers tumbling over each other, as they endeavored to pass into the crack where we afterward discovered one or two bees could get in at a time. I sprayed carbolic acid around that portion of the hive. The robbers left it immediately. Nor did they attempt to get near the crack again until the liquid had evaporated; and even then they regarded the odor with evident aversion. In the *British Bee Journal*, carbolic acid has been mentioned as an agent for driving bees out of sections. I have not yet tried it, but I believe, when the acid is strong enough, and properly administered over the tops of the sections, that it will drive the bees down out of the surplus department into the brood-nest. There was so little honey coming in this year that I did not have an opportunity to try this and other things I wanted to do.

Later.—Since writing the above, Mr. Sargent and I have just viewed, through a power of 1200 diameters, the microscopic growth which infects the larvæ. Although we are not perfectly sure of it, yet we have good reason to believe that they are the real germs. That which we discovered is ovoid and somewhat transparent. When magnified 1200 diameters, or more than a million areas, these microbes appear to be only about half as large as a pinhead—so very, very small are they. To-night Mr. Sargent starts for the University, where he will pursue his investigations as mentioned above.

Still later.—It seems that what we saw, as above mentioned, was only the *spores* of foul brood.

GLEANINGS IN BEE CULTURE.

MEDINA, SEPT. 1, 1887.

Charity . . . thought no evil. — 1. Cor. 13: 5.

We have to-day, Sept. 1, 7638 subscribers.

We have a powder-gun that kills house-flies by the use of pyrethrum, as dead as door-nails, and we killed them in Ernest's new house, without shutting the outside doors for the very good reason that his house didn't have any outside doors, as yet, to shut up. I will tell you more about it, when I get to the next chapter in my new book.

HONOR TO WHOM HONOR IS DUE.

In Our Own Apiary, p. 482, mentioning the shipment of 25 queens without a single one being dead, we carelessly omitted to say the queens were sent us by Charles Bianconcini, Bologna, Italy. He has, since then, sent us a second shipment, only two being dead, and the third shipment is expected daily. We take pleasure in recommending friend B. to any who would like to try their hand at importing; and our readers who are writing us for queens, from California, New Zealand, Sandwich Islands, and Australia, we think had better, by all means, send their orders direct to Italy. I presume, however, it would not pay to order less than ten or a dozen at one shipment.

GLEANINGS POSTERS AT FAIRS.

To those who propose to exhibit some of our goods at their county fairs, we shall be pleased to send a few GLEANINGS posters, and sample copies of our journal, empowering the exhibitor to act as agent, and receive subscriptions for GLEANINGS. For every subscription so received, at \$1.00 each, we will allow 25% commission. Remember that, if you wish to take advantage of this offer, you must not cut on the regular price of one dollar, nor can you say in any printed price list or circular that you will take subscriptions for a less amount than one dollar. The idea is, to get you to obtain subscriptions by personal work, and to extend the subscription-list of GLEANINGS. This does not apply to renewals. We have no objection to your remaining agent after fair time, but subject to the conditions above named.

THOMAS WM. COWAN.

AMONG other places which the editor of the *British Bee Journal* expects to visit is Medina. We are not advised as to the exact time when he will be with us, but it will not be many days hence. Mr. Cowan is not only a practical bee-keeper, but a careful student in microscopy. In connection therewith he has made the anatomy of the bee, and the germs of foul brood, a special study. We hope our distinguished visitor will not fail to bring

along his microscope and microscopical slides. As foul brood is still a problem with us, Mr. Cowan's knowledge and personal investigations on the subject will be eagerly sought after, particularly by Ernest, with whom microscopy has been a favorite pastime. Our friend and brother-editor should not fail to visit the Home of the Honey-Bees, so called, with its throng of busy workers.

GOOD NEWS FOR THOSE HAVING HONEY FOR SALE.

The following is just at hand:

FRIEND ROOT:—Yours of the 26th is at hand. I am surprised at the offer of 7 cts. for the honey, delivered in Medina. I am offered 9 cents here, f. o. b., and could not take less this year. Newman holds his at 10 cts. in barrels, and mine is worth one cent more in cans. Heddon gets 10 cts. in cans, f. o. b. at Dowagiac, and the best I will do is 10 cts., f. o. b. at Glenwood. When you realize and advocate higher prices, you must set an example for others to follow. O. S. COMPTON.

Glenwood, Cass Co., Mich., Aug. 29, 1887.

The above state of affairs may not be general, of course, but I shall be very glad to know that bee-keepers are getting the prices mentioned for their honey once more. It looks as if they might rejoice at the prospect of not only a good demand for comb honey, but for extracted also; and if we keep up the standard of our product I am inclined to think the prices will not go back again where they have been. At present we dare not give any quotations on the prices of honey we have for sale. When we get some we will let you know what we will take for it; but for the present we are sold out, with the exception of the California honey, which we offer at 8 cents.

Later.—Since writing the above I notice that Blake & Ripley, of Boston, quote comb in one-pound sections at 20 and 22 cts. What do you think of that, friends? And, by the way, I wonder if anybody remembers how much abuse I got years ago when I first trotted out my section that held exactly a pound of honey. Look at our market reports now, and see how it has turned out.

SPECIAL NOTICES.

DISCOUNT ON GOODS BOUGHT THIS FALL FOR NEXT SEASON'S USE.

UNTIL further notice we will give a discount of ten per cent on goods strictly for next season's use, except the following: Machinery of all kinds for manufacturing; all tin and glass honey-receptacles; tin plate, and all counter goods. On Simplicity, portico, and chaff hives, we can give only five per cent. The principal goods included under the 10% discount are foundation, frames, sections, zinc, extractors, comb-foundation machines.

A FOUR-COLOR LABEL FOR ONLY 75 CTS. PER THOUSAND.

Just think of it! we can furnish you a very neat four-color label, with your name and address, with the choice of having either "comb" or "extracted" before the word "honey," for only 75 cts. per thousand; 50 cts. per 500, or 30 cts. for 250, postpaid. The size of the label is 2½ x 1 inch—just right to go round the neck of a bottle, to put on a section, or to adorn the front of a honey-tumbler. Send for our special label catalogue for samples of this and many other pretty designs in label work.

THOSE BEES IN MISSOURI.

As the lot is not yet disposed of (see editorial on page 447, issue for June 1) we will, until further notice, make an additional discount, besides that mentioned on page 520, of 10 per cent. This will make a full-sized colony only \$4.05, and a two-frame nucleus \$1.62. If anybody wants bees at this time of year, they surely can make it pay to take them at these figures. It is true, you are to take the risk of getting them through the winter; but for several

years now there has been comparatively little trouble in wintering; and in the South there is no trouble at all, providing you have sufficient stores.

NEXT SEASON'S SUPPLY OF SECTIONS.

We wish to say to dealers who are in the habit of supplying their community with sections, and who do not make them, that we shall be glad to hear from you, stating about how many you will probably need. In order to keep our factory running through the fall, and also to avoid such a rush in the spring, we will offer, to dealers, prices on sections, from now till January, never before mentioned. We already have in stock over half a million $4\frac{1}{4} \times 4\frac{1}{4}$ sections, of different widths. If you can not buy your supply six months ahead, perhaps we can contract with you on satisfactory terms. We invite correspondence, and ask you to state, as nearly as you can, how many you will be likely to need.

KIND WORDS FROM OUR CUSTOMERS

You may be pleased to hear that, with your hives, I have taken the silver medal at the Sydney show.

F. A. HUDSON.

Bathurst, N. S. Wales, Aus., June 14, 1887.

OUR TEN-CENT BALLOONS.

The balloons came all right. I have sent one up 9 times, and still have it as good as new.

Munnsville, N. Y., July 1, 1887. F. D. WOOLVER.

I am glad to see once more in GLEANINGS something on market gardening. I renewed my subscription on purpose to get those articles, and I was much disappointed when they stopped.

W. G. BRAINARD.

Gouverneur, N. Y., Aug. 5, 1887.

I received my bees on the 22d all right, only about 100 dead ones in the box. I turned them loose on 2 frames of black brood, and they went right to work, and to-day I see they have stored about 10 lbs. of honey, and I see that the queen has laid quite a number of eggs. I am well pleased with my bees.

SINGLETON SPENCER.

Ladew, Wash. Ter., Aug. 1, 1887.

I feel that I owe all of my success in bee culture to you and your journal. Long may you live to enjoy the benefits of your hard labor. I have taken your journal for several years, and can truly say that I enjoy every article in it, and especially Our Homes. As I am a farmer, I like your market-garden reports.

S. A. MARKHAM.

Ellington, N. Y., July 13, 1887.

I am highly pleased with the smoker, and, in fact, I never have had a poor thing from you. The Novice honey-extractor I bought of you gives entire satisfaction. It simply can't be beat for the cost of the same. The honey-pails are fine, and I don't see how they can be made for the price, and material furnished.

B. E. RICE.

Boscobel, Wis., July 18, 1887.

GLEANINGS AND HER CONTRIBUTORS.

The wrapper of GLEANINGS informed me that my year's subscription has expired. Please find one dollar inclosed for another year. Through the influence of a kind friend I began taking it, and now I look forward to the advent of each number with pleasure and anticipation. Why, I would not think of getting along without hearing from those numerous acquaintances whose faces I have never seen. Their thoughts are often very inspiring. Our Homes always contains a lesson for me. The Tobacco Column is especially interesting too. It just makes me glad that so many are finally influenced to quit, and sometimes I am tempted to write those conquering heroes a letter of congratulation upon their victory, for I do want to lend my voice and vote to help in this great cause. P. Benson is a genius. What would the "sightific" world do without him?

Mr. Doolittle's article on swarming, for beginners, I read more than once, so as to know when to expect second swarms, etc. You see I had confidence to believe that it was so, if it wasn't so, if Mr. Doolittle said so, and what do you think? my bees didn't

use his reckoning hardly a bit only about one time out of a dozen! However, I am sure my bees beg Mr. D.'s pardon for their disrespectful conduct.

Shoreham, Vt.

MISS MARCIA A. DOUGLAS.

Tyler's Flour - Receptacle.

A Much-Needed Household Convenience.

In looking about for improved appliances to make our homes convenient and attractive in every way possible, we found the above implement. As soon as we saw it we felt that it was something every housewife would want. It is a can, made to hold just one sack of 49 lbs. of flour, is neatly japanned, striped and lettered, as shown above. But the most neat and convenient thing about it is the flour-sifter in the bottom. The can is hung upon a stout nail on the wall just above your table. Instead of reaching down into the ordinary flour-box or can to scoop it out, getting it on to your sleeve, you simply open the door at the bottom, place your pan underneath, and turn the crank of the sifter till you get all you want. Your flour is then all ready to use, while in the old way it must be sifted after you get it out of the box or whatever is used. You will notice, also, from the cut on the right, that the sifter is easily cleaned of all accumulations without emptying the can. The most approved flour-boxes will cost more to rig them up than this device, and you will readily see they are not so handy when done. We can furnish these flour-cans, crated ready to ship, for \$2.75 each, or we will send a crate of six, direct from the factory at Rome, N. Y., for \$12.00. They are so light that if one is ordered alone it will probably go cheaper by express.

A. I. ROOT, Medina, O.

I SHALL greatly reduce the number of my colonies; and as I hate to kill valuable queens, I offer them at 65 cents for tested Italians, and 35 cts. for hybrid queens. None older than 2 years. Shipped by return mail. T. H. KLOEF.

A Barometer for Gardeners and Farmers.

We have finally succeeded in getting a wonderfully pretty little aneroid barometer that we can sell as low as \$2.50. One of them has been carefully tested by the side of our mercurial barometer, and it follows the rising and falling of the mercury with wonderful accuracy. It seems to me that these little instruments ought to pay for themselves over and over again for any farmer or gardener, or any person who is dependent on the vicissitudes of the weather. The instrument much resembles a pretty little clock, and it may be sent by mail safely for 10 cts. extra for postage. You will remember that my method of using *any* barometer is to pay little or no attention to where the indicator or mercury stands. When you wish to know what the weather will be, tap the instrument with the end of your finger. If the indicator (or mercury) falls, there is a prospect of rain; if it rises, you are pretty safe in deciding there will be no rain very soon. If a considerable storm is approaching, the mercury will keep falling for some hours, and it will drop a little every time you touch it, even though you tap it as often as once an hour. When it keeps dropping for several hours, look out for a storm or a big wind. If it keeps rising for several hours, go on with your work and you will very seldom be misled.

A. I. ROOT, Medina, O.

Wants or Exchange Department.

Notices will be inserted under this head at one-half our usual rates. All ads. intended for this department must not exceed 5 lines, and you must say you want your ad. in this department, or we will not be responsible for any error. You can have the notice as many lines as you please, but all over five lines will cost you according to our regular rates. Of course, this department is intended only for bona-fide exchanges.

WANTED.—To exchange High-Class Fowls, eight varieties, for good type-writer or foundation. Circulars free. 14fdb A. H. DUFF, Creighton, O.

WANTED.—Honey in exchange for the following: White Hol. Turkeys. S. S. Hamburgs, printing outfit, accordion, magic lantern, microscope, books, curiosities, and mineral cabinet. Address JNO. C. CAPEHART, Spring Hill, Kan. Co., W. Va.

WANTED.—To exchange Alderbrook Poultry Farm, of 12 acres, buildings all new, for personal property or offers. 17-18d D. E. DARROW, West Eaton, N. Y.

WANTED.—To exchange small-fruit plants, strawberries, raspberries, and blackberries, for full colonies of bees. Circulars free.

17d P. D. MILLER, Grapeville, Westm'd Co., Pa.

WANTED.—To sell, or exchange for aparian supplies or good type-writer, one Model improved printing-press, No. 2, with 7 fonts of type, different kinds, and chase. Whole outfit cost \$65. Correspondence solicited. Address 17-18d J. A. WILSON, Hanover, Mich.

WANTED.—To exchange Simplicity hives and all wood brood-frames, made up or in the flat, for extracted honey. C. P. BISH, 17-18d St. Joe Station, Butler Co., Pa.

WANTED.—To exchange a Given press and dies, L. size, 3 tanks, 1 wax-strainer, ½ doz. dipping-boards, and wrenches. J. SWALLOW, 17d 2816 Mo. Ave., St. Louis, Mo.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough to these queens to pay for buying them up and keeping them in stock; and yet it is oftentimes quite an accommodation to those who can not afford higher-priced ones.

I am Italianizing my apiary, and will sell good hybrid queens for 30 cts. apiece, or four to one address, \$1.00. Stamps taken.
WATSON ALLEN, Bernardsville, N. J.

I have some hybrid queens to spare all through September, that I want to replace with tested queens, at 30 cts. each; four for \$1.00, and I guarantee safe arrival.
W. A. SANDERS, Oak Bower, Hart Co., Ga.

I will sell nice hybrid queens, of this year's raising, for 35 cts. each, or four for \$1.00.
GEO. H. DENMAN, Pittsford, Hillsdale Co., Mich.

Ten mismated golden Italian queens by return mail, 30 cts. each; also 20 purely mated Italians, rather dark color, at 50 cts. each. These are one year old, clipped.
L. L. HEARN,
Frenchville, Mercer Co., W. Va.

I have some 25 or 30 hybrid queens, which I will sell at 30 cts. each, or four for \$1.00.
JAS. ERWIN, Christiansburg, Shelby Co., Ky.

Forty untested Italian queens at 50 cts. each.
17-18d M. ISBELL, Norwich, N. Y.

Black queens, 20 cts.; hybrid, 30c; mismated, 35c.
W. G. HAYEN, Pleasant Mound, Bond Co., Ill.

About one-half dozen mismated Italian queens for sale at 30 cts. each.
WM. H. HUSE, Manchester, N. H.

CONVENTION NOTICES.

The bee-keepers of Connecticut will meet in room 50 of the State-house, Hartford, Sept. 24, at 11 A.M., for the purpose of organizing a State society. All are invited. E. H. COOK.

The fifth annual meeting and basket picnic of the Progressive Bee-keepers' Association will be held on Thursday, Sept. 22, 1887, at Mountain Apiary, the residence of John R. Reed, near Chester X Roads, Georgia Co., O. All interested are cordially invited to attend. A full attendance of the members is desired. MISS DEMA BENNETT, Sec.

The North-American Bee-keepers' Society and the North-western Bee-keepers' Society will meet in joint convention at the Commercial Hotel, corner of Lake and Dearborn Streets, Chicago, on Wednesday, Thursday, and Friday, Nov. 16, 17, and 18, 1887. Arrangements have been made with the hotel, for back room, one bed, two persons, \$1.75 per day, each; front room, \$2.00 per day, each person. This date occurs during the second week of the Fat-Stock Show, when excursion rates will be very low. W. Z. HUTCHINSON.

The Board of Agriculture of Nebraska have set apart ample and suitable space for the display of bees and honey at the State Fair, and now it is to the interest of Nebraska bee-keepers to improve this opportunity and show the people that this is a honey country, and that we need not admit any shipping of honey into our State. Shall we not now awake and meet with our products, the sweetest of the sweets, the pressure of commerce, and thus prove ourselves up with the day? The superintendent of the Apianian Department, Mr. E. W. Whitcomb, of Friend, Neb., would be glad to see you, and also a sample of your products, at the State Fair. A meeting of the State Bee-keepers' Association will also be held on Wednesday and Thursday evenings during the fair, in the Botanical Lecture-room of the State University. This room is on the first floor of the Chemical Building, east of the main building, south entrance. All are invited to attend these meetings. They will be free and interesting. H. N. PATTERSON, Sec.

CROSS BEES AND FOUL BROOD.

SOME VALUABLE SUGGESTIONS FROM FRIEND DOOLITTLE.

ON page 624 of the present volume of GLEANINGS, Mr. Vansyoc wants a recipe for stopping bees from stinging, and friend Root seems to take it for granted that Bro. V.'s bees have had access to stolen sweets, or, in other words, they "got to robbing." This may have been the case, yet there is nothing in the communication of Mr. V. to show that such was the case, except that his bees were cross. I am well aware that robbing will make bees cross, but I am also aware that improper handling will make them equally so; and the bad effects from such handling last much longer along the stinging line than it does when produced by robbing. A bee, made cross from bad handling, will follow a person around the apiary in an angry tone for days and even weeks, stinging whenever a chance is offered; while the crossness coming from robbing ceases with the end of such thieving. I have known bees made so cross by careless handling in taking off honey, on a dark cloudy day in the middle of the honey-harvest, when there was no disposition to rob, that not a person could get out of the door of the house on the side next the bee-yard, for a week after, without getting stung. When once a whole apiary gets thus aroused I know of no way to cure the trouble except to keep away from them for a week or two, till they get over what appears to them to be an unpardonable insult. No person should go through an experience like the above without learning wisdom, and not handle bees roughly or at all at such times. If absolutely necessary to handle bees at such times, they should be thoroughly subdued before opening the hive.

When such a course is pursued, no general uprising will occur.

Above I spoke of a bee thoroughly angry following a person about the apiary for days, intent on stinging. Now, in the rapid opening of hives necessary in a large apiary, a bee or two from certain hives will become angry; and if you continue to work right on, as we must, these will aggregate to quite a number during the day, so that very likely a person visiting the apiary would say, "How cross your bees are!" when in reality there would not be more than ten or fifteen bees in the whole yard but that were the most quiet kind; but these ten or fifteen bees, being ever on the alert, give a bad coloring to the whole. For years I was bothered with cross bees greeting me every time I went into the apiary; and being desirous to have it otherwise I finally fell to studying on the matter, the result of which was the making of a wooden paddle about a foot long and five inches wide at the large end. This paddle I carried along with the tools I used about the apiary; and if a bee became so enraged that it followed me a rod from its hive, keeping up its angry tone, I took up the paddle and killed it by a vigorous blow from the same. Since adopting this plan, some five or six years ago, I, or any of my neighbors or friends, can pass all through and about the apiary without fear of being greeted by cross bees. Some may object to this killing of a few bees, but I find that a bee once thoroughly angry seems to have no idea of honey-gathering afterward, but hangs about the entrance of the hive ever after that, ready to dart out at any object which may come along. Try this plan, friends, and see if you do not agree with me.

FOUL BROOD.

I was very much surprised at the premises taken regarding curing foul brood by the starvation plan.

on page 635. I can see no need of the "intermingling of bees" as there spoken of; and when the Jones plan of starvation is fully carried out, no harm could come, even did the bees intermingle after they had passed through the starvation process. With the late M. Quinby, I claim the starvation which Bro. Jones puts the bees through is not only cruel but useless. That new swarms from foul-broody colonies, hived in an empty hive, never have the disease afterward, proves Quinby correct. That such new swarms, hived on a new stand, do not spread the disease along the intermingling line, points to the conclusion that a driven colony left on its own stand would not. I should sooner think that the colonies on either side of the driven colony had caught the contagion by robbing, than that it came by the intermingling of bees. Robbing on a small scale is carried on in the apiary far more than most people are aware; and if any apiarist will watch closely he will become convinced that there are few days, when honey is not coming in freely, but that a bee-load or two of honey get from one hive to another. That foul brood can be cured by the Quinby or Jones process, I know; for I cured my whole apiary in 1872 and '73; and from what I read on page 635 it must be a quicker, more simple, and more effectual plan than the carbolic-acid plan there delineated. As a rule, when bees do intermingle they don't carry a load of honey out of their own hive into another, so that this could not be the cause of the spreading of foul brood, except in very rare cases. If you accept any other theory of the spreading of foul brood than through the honey—such as, that the disease is in the tissues of the old bees, and in the ovaries of the queen, as put forth by Mr. Cheshire, you put an effectual barrier on the queen-traffic, and an untold catastrophe on bee-keeping throughout the world.

G. M. DOOLITTLE.

Borodino, N. Y., Sept. 7, 1887.

Yes, friend D., we did presuppose that Mr. V.'s bees had got to robbing, although there was nothing in his little note that conveyed this intelligence in so many words. When a beginner reports that his bees are cross, and wants to know what to do, as a general rule we suppose that he has allowed them to get to robbing, and we advise him to immediately take measures to allay the trouble. We are well aware, that rough handling does make bees exceedingly cross, and this may have been the trouble with the bees of Mr. V. As it is, we are glad you have spoken of it. We will put it this way: Bees may be made cross by one or two ways: Namely, robbing and rough handling.

In regard to foul brood, you seem to be somewhat astonished at my statements, made in reference to the starvation plan. You say you see no need of the intermingling of bees when the Jones plan of starvation is *fully* carried out. If you will turn back to pages 630, Aug. 1, 1886, and 482, for 1887, you will see that we do not and have not practiced Mr. Jones's plan of curing foul brood, exactly as described in his book. We caused the bees, to consume all the honey in their sacks, in drawing out full sheets of foundation, after which we feed them. During all this time the bees are allowed their liberty, for we have found it is almost

impossible to shake *all* the bees from the diseased hive into clean hives with frames of foundation. There will be perhaps a hundred in the air; and over and over again have we noticed a large percentage of these bees flying into four or five different hives whose entrances were situated similarly to the parent stand. Perhaps you might say, this could be avoided. Perhaps it might be; but we have never been spry enough to close the hive and get our tools and every thing away so that the old hive might look natural before the bees in the air decided to make for home. You see, if we close the hive up immediately these flying bees would most surely enter the neighboring hives. More than this, I can not help thinking that there is considerable intermingling when the bees are quietly domiciled in their new quarters. Let us give a little fact in point: A year or so ago, you will remember, we had two Carniolan swarms in our apiary. At this time it was a most noticeable fact, that stray Carniolans were in not a few of the neighboring hives, especially in those whose entrances were in the same direction. We likewise found Italians among the Carniolans; therefore I can not but think from this and other facts which have come under my observation, that bees do intermingle to quite a large extent; and while I am ready to admit, that this quiet stealing, or "robbing on a small scale," as you term it, may be one of the ways by which the contagion may be spread, yet I think the intermingling does the greater part of the mischief.

Speaking of the starvation plan, you say, it seems to be a quicker, more simple, and more effectual plan, than the carbolic-acid plan which I described on page 635. If you turn back to this page you will see that I did not recommend the carbolic-acid treatment as being the best. I intended to give only my present knowledge of it. I am not sure, even now, that the treatment by acids is the best method of curing foul brood; but the fact remains, that ever since we began using carbolic-acid we have checked the spread of the disease in new colonies, and so confined the disease to only those colonies under treatment. On the other hand, when we were using the modification of the Jones plan, the disease spread all over the apiary, where colonies had, but a week or two before, been perfectly healthy, never having had a trace of the disease.

To your last sentence I must take a little exception. While it is possible that foul brood may be spread by means of the bees or queens, aside from the agency of honey, yet I do not think that even then we need to be very greatly alarmed. Granting that it is *possible* for queens to give the disease to healthy colonies, I can hardly see that this fact should "put an effectual barrier on the queen-traffic, and an untold catastrophe on bee-keeping throughout the world." In reference to this point I can do no better than to refer you to page 291 of the *A. B. J.* for 1885. Brother Newman there editorially gives these pertinent remarks:

Wouldn't it be as consistent to require the suspension of all business in the United States of America, because, forsooth, the cholera is expected here this

summer (aye, it is reported to be already here in some isolated cases), and the circulating medium—money, with which business is transacted, consisting of gold, silver, nickel, copper, and, worst of all, paper—is charged with spreading contagious diseases?

Many of the thousands of filthy "greenbacks" now circulating over the country have been in the possession of diseased persons, and, of course, when they pass into the hands and pockets of those in good health, they endanger the lives of all into whose hands they pass. Still we must live—we must do business—we must have and use money. In other words, we are *compelled to take the risk daily*, and yet but few, comparatively, ever catch the contagion.

In addition to Ernest's remarks, lest there be some misapprehension I will say that we have sent neither bees, queens, nor frames of brood from our own apiary since foul brood appeared. Neighbor H. has the imported queens, and does all the queen-rearing.—I want to add a little in regard to the paddle for killing bees. I have for years been in the habit of doing the same thing whenever I had reason to believe that four or five cross bees were making more trouble than their lives were worth; but I do not like a paddle so broad as the one friend Doolittle mentions. It catches air too much, and not only blows the bee away without hurting him, but the resistance of the air makes it hard to strike quickly. A strip of wood 18 inches long, $\frac{1}{2}$ inch thick, and 2 inches wide, suits me better, and I believe the bottom-bar of a Langstroth frame is still better, after you have had sufficient practice to strike the bee on the wing, and hit him the first clip. At our county fair, which is just over, we had a good deal of practice in this line. The bees came around our honey-stand; but by knocking them down with such a stick, just as fast as they appeared, they soon stopped coming. At such places, however, you want to step on the bee and kill him at once after you have knocked him down, or he may crawl up somebody's clothing and make it unpleasant for the honey-man. Commence when the bee first makes his appearance around the honey, and follow him up till you kill him, and you are master of the situation. The same is true in regard to the candy and lemonade stands. Let a hundred or a thousand bees, however, get to carrying off sweets, and there is a good chance for a lawsuit or something worse.

makes so much juice in every thing. This juice does not jell for me as sugar and fruit-juices do, but is always runny. I like honey for medicine better than for fruits. We had a hired hand one year who had sore eyes, and nothing seemed to help him. I told him that I had read that honey was good for sore eyes. I dropped a drop in each of his eyes every morning, noon, and night, and they were well in a week. It hurts, though. Honey is good for deafness. A good many people go through life with dull hearing powers, on account of hardened wax in the ear. I think honey loosens this wax. I know all that I have tried it on get better. One or two drops, dropped into the ear at one time, is sufficient. Won't Mrs. L. Harrison try this and report?

I also believe that honey and nothing else will cure any common sore throat. Take a teaspoonful every half-hour.

Mr. Root asks if such a bad state of affairs could happen at a camp-meeting. You make me smile. Why, my dear friend, I saw just the same folks at that camp-meeting that I saw at the various Sunday-school conventions that I have been attending all summer. I saw the same faces at the Fourth-of-July celebration, and at the temperance convention last Sunday, only at the camp-meeting there were more of them. The day was broiling hot, and the water-supply insufficient. The people were not so much to blame, when we consider that no refreshments of any kind were to be sold on the grounds. It would seem that, if it were ungodly to sell lemonade and watermelons on Sunday, it would have been only common every-day Christianity to give everybody all the cold water they wanted. Now, if I had been running that camp-meeting I'd have let all the watermelons come in—watermelons are so good and cooling, and I'd have had great tanks of cold water sitting all about, with half a dozen tin cups chained to each one; then I would have used all the rest of my strength in trying to prevent smoking on the grounds. The tents, the tabernacle, and three or four acres of horses and buggies were on top of a rising ground, the road leading from the bottom lands. The road that all the people came in by was new and narrow, crooked, and rough, with saplings and hazel-brush growing thickly at the sides. The young trees all over the ground, excepting just around the tents, were so close together that it was difficult to drive among them. The ground was covered with old dry leaves; the weeds and grass were dead, and as dry as tinder. It needed only a young man with a cigar and a match to have started a conflagration that would have burned up hundreds of horses before they could have been gotten out. Perhaps you will say that the young man and the cigar and the match were not present. He was there; he lighted the match, held it to his cigar, then threw it down among the leaves, and in a moment there was a blaze. They ran with blankets and quilts and jugs of water, and trampled and smothered and drowned it out before any damage was done except to the blankets and quilts. But this happened down on the creek, where there was plenty of room, and while people were eating dinner, before the water gave out. Yes, if it had been my camp-meeting I'd have gone up into the tabernacle and selected a hundred of the strongest of the brothers, and armed each of them with a club, and stationed them all about the grounds, with orders to arrest every man with a pipe or a cigar, and march them off the grounds.

SWEETENING FRUITS WITH HONEY.

MRS. CHADDOCK GIVES HER EXPERIENCE.

I HAVE read Sophia A. Bradley's letter from Australia, and in reply I would say that I have tried honey for preserving many kinds of fruits. About fifteen years ago, when I had my first crop of honey, I could not sell it, so I used it for canning and preserving fruits. I put up peaches and blackberries, all sweetened with honey. I made raspberry and blackberry jams, and peach-butter. We liked the fruit *almost* as well as that sweetened with sugar; but honey is troublesome to use, because it burns so easily. I cook all my fruit in milk-crocks; but in using honey to sweeten with I had to put the crocks in water in skillets, with nails or pebbles underneath; and it took longer, and was more trouble, than the old way. Then it

You ask if I have omitted to mention the folks who stood back and gave the others a chance. Well, I did not notice any one particularly who was standing back to set a good example. There might have been many; but where there is such a crowd, with people coming and going, passing and repassing, and raising a cloud of dust all the time that drifted in on the speakers and hearers, we can't see very well, and a man standing alone would hardly be noticed.

I think your wife did right to remonstrate with you about the refreshments at the camp-meeting. It seems to me when you and your wife have a difference of opinion, she is generally in the right. You say I did not say any thing about the sermon. The meeting in the afternoon was a children's meeting, lead by two women. They gave very good advice about raising children, but they lay too much stress against *fashion*. I claim that there are vices a thousand times more injurious to children's bodies and souls than a few ribbons and ruffles can possibly be. We heard afterward that they had a rousing good sermon at night, but we did not stay to hear it. We went home to get a drink!

MAHALA B. CHADDOCK.

Vermont, Ill., Sept. 6, 1887.

I believe you are right about using honey for preserves, Mrs. C.; in fact, I believe I have mentioned the same thing before. There is too much water in it to take the place of sugar, and this seems to be somewhat the case with even very dry candied honey.—Now, in regard to the camp-meeting. I shall have to think, my good friend, that you have not the faculty of noticing the good qualities of the great world at large as much as you do the weaknesses and the comicalities, if that is the word, or else I shall have to conclude that our real good faithful Christians do not go to camp-meeting very often. I do not believe in any thing on Sunday that savors of money-making, or that gets people interested in any kind of trade or traffic. Think of some good Christian brother saying that he did splendidly with a load of watermelons which he took to camp-meeting last Sunday! I do think something ought to be done with that young man with the cigar; but I believe I would rather risk having the good brothers armed with Christ's words than with the clubs you mention.—I believe as you do, that we should be careful how we make a fuss about ribbons and ruffles. The excessive use of them may be bad, but it is not to be compared to late hours and many other things.

OUR P. BENSON LETTER.

PRIZE LIST & CATTLELOG OF P. BENSON A. B. S.

IN order to save so menney inkuiries I have kindly gave mi consent to publish a list of hives & uther things whitch mi numerus admirers will be glad to see. Them whitch cums on a wheelbarro to get things will please hitch their wheelbarro where it will not upset & bark people's shins.

The quality of my goods is in all cases as lo as consistent with the price. Terms, invariable in ad-

vance. Drafts, munny orders or postidge stamps. Five per sent off for cash.

Hexagony Hive complete - - - - - \$5.00.

This hive gets 6 times the hunny & has took 1st premyem wharever eggzibitted. I hev skewered letters pattent on to this hive.

Material for the same flattened - - - - - \$4.75.

As this hive gits 6 times the hunney it makes it less than \$1.00 a hive.

Pattent Youreeky Feeder, - - - - - 10 cts.

The cheepest feeder noan.

Rite to use each feeder, - - - - - \$1 00

AFTER.

Abuv shows the effex of yusin the Youreeky feeder.

P. Benson's electrick loshen 50 cents a vile.

This sellybrated loshen is fed to bees to increase egg produxyen. Also to hens, polety & silkwurms.

P. Brazillyon bee sting preventative \$1.25 a bottle.

This indispensable adjunk of the aperry consists of equal parts opium, lodnum & parrygorrick, combined by a seacret prossess noan oonly to me. If enny wun takes 10 table spoonfools before breckfast, not a bee will sting you that day.

P. Benson's exsellsir moth miller trap - - - \$ 50.

This youneak device fit on the neck of a bottle fool of sweetened woter & is then hung in the aperry. It will attrack moth millers whitch kant git out.

Hunny plants and seeds of every descripshen. Prises on applekashen.

Beleavin that artafishell pastyourage is the she tanker of suckcess in bee keepin, I hev devoated a feelled of 10 achers to the excloosiv produckshen of hunny plants & seeds so that my customers ken rely on a pewer artickel.

P. S. It will be purceved that this is the 1st 1/2 of my cattellog. The last 1/2 (half) was printed two (2) weeks ago. Sum pceple is so shiffless thay never finish up ennything thay begin. Ime not that sort, so I was tound ide hev this cattellog finished if I never begun it. Orders is cummin in in a noomerous manner.

BEING IMPOSED UPON.

A GOOD-NATURED COMPLAINT.

ISEE by GLEANINGS how many people you let impose upon you, and so I am going to try it a little. I bought a swarm of bees last spring; and, as you know, this is a very poor year for a beginner. I have so far paid out \$15.00 for them, and shall get little return this season. Now, I want your A B C book very much, but haven't the dollar to pay for it, and I am going to tell you the reasons why you may send it to me for nothing, if you want to:

1. Because you let other people impose upon you, and I don't see why I can't.

2. I take GLEANINGS, and hope to right along.

3. I sent to you for half a bushel of alsike seed

last spring, and ordered it to come by freight, with three weeks for it to come in before we needed it, and you sent it by express, which cost me 75 cents; and when we got it from the express office there was a hole torn in the sack. You could press a good-sized egg through it. I don't think there was much seed lost, but it was a bother, and I want your A B C book so bad. If you do not want to send it, please don't. I shall not be at all mad. I have made out as bad a case as I can, only to tell you how badly I got stung yesterday.

MRS. CHAS. PENNINGTON.

Cottage Grove, Minn., Aug. 11, 1887.

My good friend, if people are imposing upon me there is one pleasant thing about it—I don't know it; and, you know, "where ignorance is bliss, 'tis folly to be wise." May be I do sometimes do a little *more* than my part in trying to have things pleasant and satisfactory; but what harm does it do, when I have all I need, and more too, of all that the world can furnish? May be it is true, that my wants are not very great; and if this is true, I am glad again. Your first and second reasons do not count very much for a smoker; but if our clerks disobeyed orders, as per your No. 3, I think we had better send you the book and call it square. If it is more than you ought to have under the circumstances, why, just lend it to your neighbors, and do good with it, and that will make it all right, so far as I am concerned.

THAT BEFORE-DINNER NAP.

ALSO SOME IMPORTANT SUGGESTIONS IN REGARD TO THE USE OF SLATTED HONEY-BOARDS.

FRIEND ROOT:—I want to fight some more about the nap before dinner, and I shall be heartily glad if you whip. I consider it a matter of exceeding importance that we should understand this matter thoroughly, and know just what ought to be done. We are agreed that the twenty minutes' rest before dinner is desirable, and I have raised the question, "Where is the chance for it?"—a question which you haven't answered. I venture to say that 999 out of every 1000 women in the GLEANINGS constituency will say the thing can't be done. Of course, I mean where the woman has no help, and the thing to be regularly continued. I can think of some meals where it is practicable, as a meal of bread and milk, or of cerealine and milk, or any meal where every thing is cold and no cooking done, and perhaps it would be better for all if there were more such meals. But in most cases there is a cooked dinner. Suppose it is a plain dinner of beefsteak and potatoes, plain boiled. "Just before dinner time," when the steak is done and the potatoes boiled, let the cook lie down for twenty minutes, and in what shape will the dinner be?

Now, Mr. Root, you didn't ask your wife about it, did you? I have great respect for her opinions; and if she agrees with you I shall say the thing is feasible, and try my best to put it in practice. The after-dinner rest I frequently insist upon, sometimes "by force and arms." Our good friend Mrs. Harrison (p. 669) takes an hour's rest before eating her

dinner—does she cook the dinner before that hour's rest? I suggested to my wife that it would be the right thing for her to rest before dinner, and she replied, "I guess you'd get some funny meals." Then with a good-natured laugh she added, "There are some things men know precious little about."

IS THE SLATTED HONEY-BOARD DESIRABLE?

Referring to page 656, I have given a pretty fair trial to the plan of using supers without slatted honey-boards. I can hardly believe that I got any more honey than with. By the use of a bait section, which I should use in any case, I have no trouble about getting the bees to occupy the sections promptly, as soon as they have any thing to store in them. Until this year I did not suppose they would occupy them when honey was not yielding; but during the terrible drought this summer I found supers filled with bees, although they were not storing an ounce, and all the sections except one had nothing in them except empty foundation. Between the top-bars of the brood-frames and what is placed immediately over, I have always found brace-combs and honey, or else bee-glue, if honey is stored above. It is possible that just such a space might be made that neither glue nor comb would be placed in it, but in actual practice I have never reached it. (By the way, if I had not so many hives already on hand I would give a trial to the plan of J. B. Hall, of Woodstock, Canada. He showed me frames that he uses, with top-bars an inch thick; and, if I am not mistaken, he said no brace-combs were built over such top-bars.) Now, there is waste in having the space filled over the top bars; and if a honey-board is used, this waste occurs once in a season; whereas if no honey-board is used, and three supers are put on in a season, putting each super, as is the practice, next the brood-nest, there will be three times as much waste. So if the honey-board is no hindrance to the bees going up (as I think it is not, with proper management), it looks as if more honey could be obtained with than without honey-boards. I dislike the job of cleaning up these honey-boards when they are taken off at the close of the season. It is a sticky, dauby job, if at once cleaned off; but as there is no hurry about it I put a lot of them over a hive, confined so no robbers can get at them; and after the bees have cleaned off all honey I clean off the wax at my leisure. Bad as this is, it is several times worse if no honey-board is used. Instead of one job for the season, each super, when changed from its place immediately over the frames, must be cleaned off; and this with the dripping honey in the way, right in the busy time when every minute counts.

HONEY SEASON OF 1887.

The worst I ever knew. One word tells the whole story—drought. My colonies have been strong all through the summer, and I have taken in all something like 300 pounds of section honey, mostly from the Wilson apiary, a good share of this being a single section (the bait) in a super. In some cases, if not all, the bees filled this one section of empty comb when there was abundance of empty room in the brood-combs. A curious feature has been the absence of trouble from robbers throughout the entire season, possibly because they have been handled so little. At this date, Sept. 8, the bees seem to be working quite busily, at least in the forenoon, but no gain of honey appears in the brood-combs. They are, however, full of brood,

which must take no little honey; and on looking through a hive, the full combs of brood look as if the bees thought it were spring. There are other appearances of spring since the rains, such as the reviving of the brown pastures, and the dandelions are coming out in bloom. The present outlook is, that I shall buy about two tons of sugar this month for my bees.

C. C. MILLER.

Marengo, Ill.

Friend M., Mrs. Root and I have a standing disagreement about that before-dinner nap. There is not any disagreement about *my* nap before dinner at all, for I always find a place fixed, a pillow ready, doors closed, and children chased off; and if I don't get to sleep awful quick, I notice she stands sentinel all around that part of the house. There is not any question but that this is the only thing for *me*; but although her health is not much better than mine, especially when she works more than she ought to, she utterly repudiates the idea of a nap before dinner, for herself. She says by actions, that it is quite important that *my* life should be prolonged, but that in her case it is not very much matter. Now, that stirs me up every time I think of it, and I am disappointed in you, friend M., to think that you made such a feeble fight for the queens of our homes, as Prof. Cook calls them. What shall we do? Why, have one of the grown-up daughters bring things to dinner smoking hot, or else get some relative, whose health does not need this nap; or, if you can not do that, get some good sensible woman, and pay her a good round price for being sensible, that your wife's life may be prolonged. Mrs. Root generally comes out ahead in all disagreements, but I don't believe she will this time.—Thanks for the important points you bring out in regard to the use of the slatted honey-board. I think I shall have to apologize to friend Heddon right here. He tried to make me see this very thing some time ago, and it did get through my understanding exactly.

BEST HONEY FOR WINTERING.

"BUG-JUICE" A WINTER FEED.

ON page 615, Aug. GLEANINGS, O. O. Poppleton gives his experience and conclusions on the best honey for wintering; and as your foot-notes call for others on the same I will give mine, which in some respects is right the reverse of friend P.'s. He says, that "the longer and more abundant the flow of honey, the better the quality." In 1878 we had the most prolific growth of white clover that I ever saw. It was fairly a burden all over the ground, and every head was brimful of nectar, and it held in bloom for fully three months, and of course the hives were full of it for winter stores; but, alas! it proved the worst that could be, for nearly every bee died the following winter. It was my first winter in trying to keep a large quantity of bees, and so my first loss. I noticed that the honey that year was almost as clear as water, and almost as thin too; even that which was fully ripened and capped by the bees would flow like water, almost, when a comb was broken. Ever since then I have found that, whenever clover honey comes in rather slowly it is always

very thick and heavy, and of a golden tinge; but when it comes in faster it is more clear, and thinner.

Now, to sum up my conclusions of ten years' experience, I will say that I do not care from what source the bees get their honey for winter use, nor how early or late in the season; so long as it is "thick and well ripened" I am fully convinced that it is all right for them; and I have further concluded that it has not been the "honey," but something else that has been the cause of our past great losses in wintering.

I am now going to tell you something that will not be believed by many who read it. I should have written it long ago, but I concluded that it would not be believed; nevertheless, I tried it and I know it. It will be remembered, that a few years ago there was a general prolific flow of honey-dew, or "bug-juice." Well, I got my share of it, and but very little of any other honey, and a great deal was said against leaving it in the combs for winter stores. The editor of the *A. B. J.* was particularly emphatic against it; but as I had nothing else for them I left it in, and my bees nearly all died with the dysentery. Two years later I had quite a quantity of this same dark strong honey-dew honey that I had extracted and kept over, as it was not fit to sell, and I could not eat it myself. I fed it to half a dozen or more light stocks during the winter, by putting the candied honey on the frames right over the cluster. I have written up this way of wintering several times before. They had nothing but dry combs when cold weather began, and I could never ask for bees to winter nicer. They were dry and healthy all the time, and their only food the whole winter was the "bug-juice." I will finish by repeating that I don't care what their stores are, so long as it is not thin and watery, and I can have other conditions to suit me. A. A. FRADENBURG.

Port Washington, O., Aug. 29, 1887.

Friend F., by reference to our back numbers you will find at least one other experiment in this line. A Mr. Pierson, of Ghent, Summit Co., O., lost his bees terribly by spring dwindling. Several were at this time asking if we would advise them to use combs of sealed stores that came from hives where the bees died. I believe our veterans, including the editors of the bee-journals, most of them, advised against using these stores that seemed to be so disastrous during at least one winter. Friend Pierson said, however, he was going to try it. He accordingly prepared quite a number of colonies with combs of sealed stores taken from hives where the bees had died so badly. Now, although these bees had nothing else whatever, every colony wintered splendidly. This experiment seemed to indicate that it was not the quality of stores that killed the bees, and I am inclined to think yet that a good deal of these disastrous losses were in consequence of a sort of distemper or contagion that got among the bees and swept off whole apiaries. May be proper care and protection will do very much to enable the bees to withstand the distemper. I should be very glad indeed to think it is the result of skill and experience, that enables us to winter lately without losses when we had such terrible disaster, winter after winter, ten or twelve years ago.

A BRIDGE FOR CLEANING SECTIONS.

A DESCRIPTION.

AT the convention at Albany last winter I made mention of a bridge I invented for cleaning propolis from honey-sections. If I am not mistaken you said you would make mention of it through GLEANINGS. As the time for crating honey is near at hand, I am quite sure the bee-fraternity, if they once use one, would consider it indispensable: for myself, I would not do without mine for ten dollars. It is made as follows:

Take a piece of heavy tinned wire cloth. It must be heavy wire, so as not to bend down when the sections of honey are put on it. Cut it about 12 or 13 inches square; turn every edge at right angles, $\frac{1}{2}$ inch. Make a frame that will fit nicely inside of the folded edges, and tack fast. Get out for this frame 4 strips, $\frac{1}{4}$ x 1 inch, or about. This bridge is then completed. Lay it on a table, or whatever you wish to clean your sections on, and go to work. I think you will exclaim "Eureka!" The propolis goes through the meshes of the wire, as do also the drips of honey from the unsealed cells around the edges, and does not daub and muss up the sections. It does away with the bother of brushing away the dirt, and wiping up drips of honey. When the refuse accumulates under the bridge, raise it up and clear it, and proceed again.

The honey season here has been a very unsatisfactory one. The yield is about half a crop. White clover yielded very little. Basswood was in full bloom, but yielded sparingly. Bees worked well on sweet clover until the excessive rains set in in July; since then it has been too wet. They have worked some on buckwheat, but now we are having a flood of rain, and storing from that source is at an end; and as buckwheat is the last source from which bees store surplus, we shall have to be contented with half a crop. G. J. FLANSBURG.

So. Bethlehem, N. Y., Aug. 23, 1887.

Friend F., since you mention it I remember quite well your little device, and I thank you for calling my attention to it again. Please excuse my carelessness. The simple idea of itself, of placing your work on a strip of wire cloth, properly supported, is one for which we owe you a vote of thanks.

REPORT FROM E. FRANCE & SON.

CONTINUED FROM PAGE 655, LAST ISSUE.

HOW about this year? We did not mind the loss of the 97 colonies that died, for we still had fifteen more colonies than we had a year ago; and by the time white clover should have blossomed we had all our bees strong and in good condition, ready for the harvest—which did not come. The dry weather last year killed out the clover; so when the time came this year for it to blossom I discovered there was none to blossom, except on low ground. The drought of this year drove the stock on to the low ground to get a living. They kept the clover cropped so close that the blossoms were picked off before they had time to open. As a consequence, our bees never got a taste of clover honey. We have but very few fruit-trees here, but we had a good crop of dandelion that helped a little. Our bees had plenty of last year's honey and honey-dew to work

on in their hives, and they used it to raise brood. There was no honey coming in, so the queens had full swing and filled all the empty combs with eggs. These came right on, and were soon bees.

There were a good many young queens of last year's hatching which were not clipped. We were very anxious to clip them, as the bees were getting very strong, and would be very likely to swarm. Those unclipped queens would be sure to go to the woods with their swarms. We could not open them, as there was no honey coming in, without starting robbers to work. We usually clip queens and start a few new colonies when fruit-blossoms and dandelions are out; but we could not do it this year. I managed to work in the home yard, some evenings; then we (in all, four men) went to one of the other yards and worked each of us two colonies and then had to quit, as we could not work any more. Word began to come in from all the yards that the bees were swarming and going off. We never had such a time before.

FRANCE'S BEE-TENT.

We started for home, determined to make a tent. I told my son to build a tent while on the road home, and I would do so myself, our two hired boys to do the same thing—that is, build it in our minds. We traveled about a mile as still as a Quaker meeting, and then began to talk a little. We soon all decided it should be eight feet square, to work one of our quadruple hives, with four of us at work. It must be as large at the top as at the bottom, and it must be high enough to stand up in. Having decided on the general plan of it, we made one in detail as follows:

We first got out four legs 7 feet 3 inches high, 2 inches square. Near the bottom end we drove in two staples—one about 8 inches higher than the other. We next had four iron pins made out of half-inch round iron, and about 18 inches long. These we slipped into the staples at the foot of the posts, and drove them into the ground, to hold the foot of the post in place. A head was provided for on top of the irons, by which to pull them out of the ground. We bored a $\frac{3}{8}$ hole down in the upper end of the posts, 6 inches deep. We then got out four straight-grained inch boards, each 2 inches wide, and 7 $\frac{1}{2}$ feet long. These were for the top. One inch from the end of each piece we bored a half-inch hole, and rounded the ends so the square corners would not tear the cloth. For a covering we used cheese-cloth costing 5 cents a yard. This was made into a large sack so as to slip over the frame easily when put together.

The tent is now ready to put up. It takes four men (boys will do) to handle it. Each one takes a post and a top-board, and an 8-inch bolt, $\frac{3}{8}$ of an inch in size. Set up the posts; lay on the top-pieces, and drop the bolt through the two boards at the corner, down into the hole in the top of the posts. Next, drive the iron pins into the ground, and you are ready for the cover, which is then slipped over the frame. Raise up one side and step inside.

We are safe from outside bees; besides, those inside won't be likely to sting, for they soon find out that they are in a trap, and will only try to get out. We found the tent was just the thing. We could work the four colonies that were in the tent. Having finished operations and closed up the hive, each of the four hands takes a post and pulls up the pin. At the words, "All ready!" they all raise up the tent, bodily. The tent is carried and set over an-

other hive. The corners are then set out so as to tighten the cloth. The pins are driven in as before. If there is a strong wind, the tent is stayed with some stout string. We used some of the tarred twine so common in the stores.

With the tent we worked all the bees over, clipped the queens, and made new colonies, filling out the old colonies with combs from the dead ones, as long as we had them. This gave room for the queens to lay more eggs and raise more bees, which they did; but as long as there was no honey coming in they would not build new combs. When our old combs were used up we filled out the old colonies with empty frames with 1½-inch starters of foundation. But until the basswood blossomed they would not build combs. They swarmed; but as the queens were clipped they could not go off. They would go back, and perhaps two or three swarms would come out at the same time, when they would be quite sure to all bunch together on one hive. I think I have found this summer a full barrel of bees hanging on and under one of our large quadruple hives. They were the worst about that soon after the basswood commenced to blossom. At that time we got over them as fast as we could, which was about once a week. We would find from one to two hives in that fix in going about once around. Such a sight, and so many bees, I never saw before. If I could have sold them by the pound I could have made a fortune. I went to work and divided them up into new colonies, making five or six colonies out of the bunch of bees and brood-combs from other hives. The bees appeared to be tired of fooling, and they accepted a home, stayed where I put them, and went to work. When I saw we were not going to get any honey except what we could get from basswood, I decided to make just as few new colonies as possible. But the bees had nothing to do but to raise bees. They had plenty of their old fall honey to feed the young brood. We had a pretty fair run of basswood honey for about 12 days. As soon as the bees got at work on the basswood we started the extractor, and emptied out seven barrels of (about 2500 pounds) the old dark last year's honey-dew. We now wanted the bees to fill up on basswood honey to winter on, but there was too much brood in the combs, so we extracted most of the combs the second time, and get out seven barrels more. This last was basswood honey. We took it out to give room for more, expecting to feed it back. I don't know yet whether it will be wanted for feed or not, as we have not examined lately to see how well they are off for honey.

Now, had I known just how the season would have been I would have had all the combs full of honey at the close of the basswood season. If I had taken all the queens away just before basswood came out, there would not have been any more eggs laid; and what brood they had on hand would have been about all hatched out, and their places in the combs filled with honey. Then they would have been in good shape to winter. As for queens, I would have let them raise a young one while they were filling up, or I could have kept some of the old ones in nuclei to fill vacant places. Then I should have had no trouble about the bees swarming and bunching in.

I don't know just how much our bees have increased, as there are three yards not counted up. The other three yards had 198 colonies in the spring. They have now 249—an increase of 51. I think per-

haps the other three yards have increased about the same, which will just about make up our winter loss. I don't know whether the bees have as much honey now on hand as they had at the close of the basswood flow or not, as I have not looked lately. But, such a call for honey! Orders come with every mail. Last year we had a big crop, and worked hard to get rid of it at low figures; but this year we got none and everybody wants to buy. The dry weather this year, I think, will cut clover crop off for next year. But we are not in Blasted Hopes yet. We have lots of bees, and are going to try hard to winter them. We had a good rain last night for the first time since July 2. E. FRANCE.

Platteville, Wis., Aug. 11, 1887.

May be your plan of a bee-tent might answer the best of any thing that could be devised, for your own use; but I should object to it in our own apiary for several reasons. First, whenever it becomes necessary to remove the tent to another hive you are obliged literally to "pull up stakes;" second, to use it to any advantage it requires four men (or boys) to handle it; third, it would take too long, it seems to me, to put it together ready for use, and slip over it the cheese-cloth sack. While it is a great convenience to have the top as large as the bottom, yet we prefer to have a tent with a gable top, for this reason: The bees inside will keep working toward the central line; and having reached there they will escape through the openings at the top. Different apiarists may have different ideas as to what a tent should be; but here at the Home of the Honey-Bees we prefer to have one weighing not over five pounds—a tent that one man can handle easily—one which can be folded quickly, and opened out just as quickly. I believe it is no more trouble to use our tent over the hives than it is to work the hives without a tent. I believe if I had quadruple hives, as you have, I should make the same kind of a tent that we advertise, but perhaps two or three times as large. However, as I said before, each one has his preferences and his own ideas of convenience.

FLORIDA.

HOW W. S. HART AND HIS NEIGHBORS SUCCEEDED THIS SEASON.

THE honey-season in this part of Florida closed about the last of July, and left us with about one-fifth of a crop, as a rule. My own report is, nine 400-lb. barrels from about 100 colonies. The bees in my immediate neighborhood have not done as well as those a few miles either north or south of here. To the north and on the peninsula, they had a fall flow that we did not get, and that helped to keep the bees there in better shape for the summer flow. To the south, the black mangrove was not hurt as badly as here by the great freeze of 1886, therefore yielded more freely. In fact, bee keepers from that way tell me that the blossoms often hung full of honey from morning until night, and that their bees being in poor shape was the only reason for their not getting a full crop of mangrove honey.

The season of 1886 proving an almost total failure, from the effects of the big freeze early in that year, then all the first part of this season proving equally

poor, many of our apiarists got discouraged, and either gave up the business for the present or else let their bees take care of themselves, to a great extent. My own have been taken care of in a very slipshod manner for the past two seasons, as there was more profit to me in giving my time to my orange-groves. The prospect now is, that next season will give us a full crop again, and I now feel that I can again invite brother bee-keepers to come to this country, with as good a prospect of their being successful in their line here as any where else in the U. S. They must remember, however, that the ordering of the honey crop does not lie with me; and as I am thoroughly human, my judgment may err.

The two who seem to have best success along this river this season are Mrs. Dr. Goodwin, located three miles north, on the peninsula, who took, I am told nine barrels of honey from about 45 colonies; and Mr. Storer, five miles south, on the main land, who took 15 barrels from about 125 colonies. These barrels, I suppose, hold about 400 lbs. each. I have so far received no other reports that compare with these, although there may be others who have done as well, whom I have not heard from. The comb-honey producers have not reported yet. The season has been exceptionally dry through the summer months, but I do not think that its being so shortened the crop to any extent. W. S. HART.

Hawks Park, Fla., Aug. 23, 1887.

CAUSE OF SOUTHERN HONEY GRANULATING.

DOES IT PAY TO KEEP BEES?

MR. G. W. BECKHAM, of South Carolina, asks in GLEANINGS, Aug. 15, p. 626, the cause of his honey candying. I believe his honey and ours of this year, or what surplus we got, was gathered from the pines, secreted by a plant-louse, as illustrated in Cook's Manual, Fig. 123. I saw large drops of it dry on the pine buds, and they were nearly as white as granulated sugar. I left two cases of this honey, which was taken during May, our honey season, to have them completed. Two weeks ago, when removed, the bees had taken it nearly all below, leaving me a lot of nice combs in sections for next year's use.

This is my fourth year with bees. I began in 1884 with 4 colonies; expenses, \$85.08. I received on hives, etc., \$29.67. No surplus honey received. I began in 1885 with 6 colonies; expenses, \$24.39. Received 45 lbs. of honey, valued at \$6.00. I began in 1886 with 10 colonies; expenses, \$16.80. Surplus honey, 41 lbs. Value, \$5.00. Receipts in full, \$15.00. I began in 1887 with 11 colonies. Increased to 17; expenses, \$11.25. Surplus honey, 37 lbs. Value, \$4.50. Value of stock on hand, including bees, \$75.00. Expenses for the 4 years, \$137.52. Receipts for same, including stock on hand, \$130.17. So you see I am out over \$7.00 in money, and my time in manipulating the bees. Would you advise my keeping bees with the expectation of getting a profit? G. W. O'KELLEY.

Harmony Grove, Ga., Aug. 29, 1887.

I should say that the first thing you need to do in order to make your bees pay in the future, is to cut down the items of expense. We can manage to get along on much smaller outlays, if we only think so, many times.

I should advise you not to lay out any more money on bees and supplies just at present. Take what you have, and make them bring some return.

KEEPING BEES IN DIFFERENT APIARIES.

SOME EXCELLENT SUGGESTIONS FROM THE DADANTS.

DEAR MR. ROOT:—The reading of the answers to Query 3, and of the remarks that you added, have called to my mind one of our great arguments in favor of keeping bees in several locations a few miles apart. A great many imagine that the dividing of bees into several apiaries is attended with more expense than profit. Yet it is a fact, that we have succeeded better with a number of small apiaries than we used to do with only one or two large ones. Leaving aside the question of overstocking, there is a decided advantage in keeping bees in different places, as the yield is not everywhere the same. Taking the present season as an instance, in our locality, the yield of different apiaries only a few miles apart is quite different, and we find a profit in apiaries placed on the lowlands while the crop is a total failure in other places. On the other hand, in wet seasons the yield on the hills is very great, while it is almost null on the bottoms. An apiarist can have no idea of the difference that a few miles will make, owing to rains, the soil, and the pasturage, until he tries bee-keeping in different apiaries. We have apiaries located a few miles north of us, in the hills, that usually yield a good crop of clover, and that produce little else; on the other hand, our lower apiaries, on the Mississippi bottoms, yield nothing but fall honey, but in this they never fail. Therefore, on the principle of not putting all of one's eggs into one basket, we believe in spreading the bees and occupying different fields. We do not agree with those who think that bees can go safely four or five miles for honey. We have apiaries three miles apart, that yield altogether different crops, both in quality and quantity, and such would not be the case if bees could travel as far as represented. Our home apiary is only two miles from the river bottoms, and our bees hardly ever reach it. We have seen seasons when we were compelled to feed, while those who had bees next to the bottoms harvested a fair crop. The crop of each of six different apiaries differs in quantity, quality, taste, and color. C. P. DADANT.

Hamilton, Hancock Co., Ill., Sept. 8, 1887.

Why, my good friend, you have suggested a very important point indeed, and one that I fear has been a great deal overlooked. This matter of putting your eggs all in one basket is a serious one in many kinds of business; at least, where a new hand starts out by putting all the eggs he has got, or can scrape up, into one single basket. If the basket is upset, he is down completely; and since you suggest it, I have noticed a very great difference in the honey-flow, even in a short distance. When friend Doolittle claimed that bees *could* fly four or five miles, you may remember that I was very slow to be convinced; and with the facts you have given above, I still think that, even if it be *possible* for bees to fly such

great distances as mentioned by friend March, of Washington Territory, I do not believe they often do it where we have ordinary landscape, diversified with forests, hills, valleys, etc. When we first brought the Italian bees into Medina County, I went to considerable time and expense to ascertain how far they were in the habit of going for stores, and my experience was decidedly like yours. At one time, when there was almost nothing to be found except a buckwheat field two miles away, they did store some buckwheat honey, carried that distance, but this was the exception. Italians were seldom seen working on clover, basswood, or any thing else, more than just about a mile and a half from the apiary. Now, if you were compelled to feed your bees when you have positive evidence there was forage only two miles away, it seems to me the experiment is pretty conclusive. Is it not possible, however, that the bees that were gathering stores procured these stores, say a mile or more in some other direction away from the home apiary? If we are going to scatter our bees in different apiaries, it is quite important to know just how far apart we ought to scatter them. Friend Cowan informed us that Captain Hetherington had at present, I believe, 2800 different colonies of bees, and these were located in something like 40 different apiaries, if I remember correctly — some as far away as six miles from the central home apiary.

WHAT ARE THE CONDITIONS FOR EXCLUSIVE BEE-KEEPING?

DR. C. C. MILLER CONSIDERS THE SUBJECT.

A CORRESPONDENT has lately asked my opinion as to the advisability of his giving up his other business and keeping bees exclusively; and questions are frequently asked, bearing in the same direction. So many things must be taken into consideration that it is exceedingly difficult to give any thing like a definite answer; but I will try to give some hints that may help toward making a decision; and if I should say any thing in any way misleading, I feel sure it will not escape Mr. Root's sharp eyes, and I will trust to him to set me straight.

I suspect we are growing toward the time when honey will be largely raised by men who have no other business, and I suppose there may be a number such now; and yet, aside from myself, I do not know of a single individual for certain. Mr. Root, how many do you know who make honey-raising their exclusive business? I have often thought I should very much like to know their names. Perhaps it would not be uninteresting to others for you to bring them out. Of course, I do not mean those in some business connected with bee-keeping, for that would bring in such men as yourself, G. B. Lewis, etc. Now, if there are very few exclusively in the business, it is just so much evidence that, of the thousands of bee-keepers, nearly all have concluded that it was advisable for them to turn their attention partly to some other pursuit. In this material age, perhaps most have summed up the whole matter in these few words: "There isn't money enough in it." For those whose sole aim is to make the most money in the shortest possible

time, it would be hazardous to recommend bee-keeping as a sole pursuit. But there are some who care more for happiness than money—some who, like Mr. Root, could not be induced by any salary to give up a life that suits them for one less healthy and happy. To such I would say, be a little slow about putting yourself in a position to depend entirely upon bee-keeping. Whilst you may make a success in a series of years, the good years overbalancing the bad ones, you are not sure but the very next year may bring an entire failure, and you must be ready for it. Better give up your hold of other business gradually, if you can.

I doubt if any one should go into bee-keeping exclusively until he has at least enough ahead to go through one year without making any thing. For it is so unlikely that two consecutive years of entire failure would occur, that, if I had a strong taste for bee culture, I think I should take the risk of giving up every other business if I had one year's living ahead. Of course, I include in this that a sufficient apiary is owned and paid for. What is a sufficient apiary? That depends. First, figure up how much you need for annual living. Then count for an average location perhaps \$4.00 profit per colony, or, better still, find out what your actual profit for a number of years has been. Dividing the annual living expenses by the profit per colony will give the number of colonies required. But it will not do if you have kept bees one or two years, having ten colonies with a profit of \$10.00 per colony, to count that you can average the same straight along with 100 or more colonies. It may be, that the very next year would bring down the average of your 10 colonies. Moreover, it is pretty certain that 100 colonies would not give you the same yield per colony that ten would. Another thing: If you have never kept more than ten colonies, it is not certain that your part of the work will be as well done with 100. So don't jump into the middle of things, and buy a large number of colonies, but *grow* into the business.

I am aware that, in the foregoing, my advice is somewhat vague; but the nature of the case hardly allows any thing else. If you have the right taste for the business, and the right stuff in you, work your way up—stick to it; and although you may not die a millionaire, you will live a happier life, eat better-tasting victuals, and be more comfort to those about you, than the majority of millionaires. If I may be excused for referring to my own case, I turned my back on a city life with \$2500 a year and all expenses paid, settled down as principal of a village school at \$1200 a year, and paid my own expenses, that I might work into bee-keeping. The time may come when I shall regret it; but it is not here yet; and for the past ten years I have tried what exclusive bee-keeping means.

T SUPERS FOR BEGINNERS.

In my book I hesitated somewhat about recommending T supers for others, and have been asked whether I would recommend them for beginners over wide frames. I think it requires no more skill, if as much, to use the T supers, and I would advise their trial, even for beginners. There is no telling, however, how soon something better than the T super may take its place.

C. C. MILLER.

Marengo, Ill., Sept. 5, 1887.

Friend M., I can not call to mind just now many who make the production of honey their sole business; for, in fact, it is not

very common for people to put all their eggs into one basket, in any line of agricultural industry. Our neighbors Shane and Chase are working principally, I suppose, for honey, yet both of them do something at farming, if I am correct. Friend Doolittle is emphatically a honey-raiser, but he receives at least a moderate income in writing for different periodicals, and I believe the same might be said of yourself and a good many others. Most specialists have, however, I believe, followed your plan by getting entirely into bee culture by a series of steps. Sometimes they get out of bee culture also by a series of steps, and I think this is a far better way than to abandon the business in disgust, and sell off the fixtures for what they will bring. Bee-keepers may sometimes make a good income the very first year, but I believe that such is not generally the case. My experience is greatly in favor of persistently holding on to any line of work that seems to be to your taste. You will eventually reap your reward, if you stick to your work long enough.

COMB VERSUS EXTRACTED HONEY.

J. A. GREEN'S EXPERIENCE.

THE question as to whether it is more profitable to produce comb or extracted honey will probably never be settled to the satisfaction of all. One man declares that he can get three times as much extracted as comb honey, while another insists that he can secure nearly if not quite as much comb as he could of extracted, and both are ready to say that the other man does not know how to raise honey. Both are practical honey-producers, and prove the excellence of their methods by raising large crops of honey. Somewhere between these two extremes lies the truth.

I suspect that a great deal of the difference in results is to be attributed to environment. Much depends on the locality and the character of the honey-flow, and still more on the method and the man. I am almost inclined, though, to call the character of the honey-flow the most important consideration. With only a light flow of honey, especially when in connection with cool weather, bees will store honey in empty combs when they will do little or nothing in the way of comb-building. Let the honey-flow be increased, and the difference lessens until at a certain point it is at its lowest. At this time, I think the best method will secure fully three-fourths as much comb honey as could be had of extracted. Going beyond this point, as is done in our best honey-flows, we find that bees that are well supplied with empty combs will bring in a much larger quantity—sometimes three or four times as much—than they can build combs for.

With the honey-yield just right, there will not be a very great difference in the amount of comb or extracted honey that can be secured; but above or below this point, those who run for extracted honey will come out ahead.

The generally accepted proportion of twice as much extracted as comb is nearly right on an average, with the balance a little in favor of comb if

the extracted honey is well ripened. Three times as much of the half-ripe article usually extracted as honey can be easily secured.

There are other things to be taken into consideration besides the comparative amounts of comb and extracted honey that can be secured from a given number of colonies. A man can take care of a great many more colonies run for extracted honey than for comb, because bees properly managed for extracted honey never swarm, and because the work of taking off honey, instead of being crowded into a few busy weeks, interfered with at the same time by swarming and other distractions, may be distributed through the season, or done wholesale at a time when there is no other work to hinder, at the pleasure of the apiarist. An apiary away from home can be managed much more safely, and with less trouble, if run for extracted honey.

When it comes to marketing the honey, if it is to be shipped off to be sold on commission, there is a great saving of labor and expense in favor of extracted honey, as it requires no manipulation to make it ready for market. Barrels, too, cost far less than crates, and are practically safe from injury in transportation, while comb honey is always liable to breakage.

If the honey is to be put into small packages to be sold at retail, the labor and expense of packages bring the price nearly up to that of comb honey, as comb can be sold in a home market without any expense for packages, which is not so easy for extracted, except at home or by peddling. If you are in a neighborhood where people will pay nearly or quite as much for extracted as for comb—there are such places—it will be to your interest, of course, to produce extracted honey.

Each one must decide for himself as to which will be more profitable in his locality; but a little advice may be acceptable to some. If you want to keep bees with the minimum of labor and attention, produce extracted honey. If you can not produce nice white comb honey of good quality, produce extracted honey. If you have a good home market at fair prices for extracted honey, by all means supply that market. But if you are obliged to ship your honey off to be sold on commission, you will find, as a rule, that comb honey will pay you better. If you can secure most of your crop in nice white comb, you will probably get more money out of it in that shape than if it were extracted. If in your home market a prejudice exists against extracted honey, as is too often the case, it will not pay you, as a general thing, to fight that prejudice. There are many places where only a definite amount of honey will be used, and you can sell just as much comb honey as you can of extracted. There is a double loss in selling extracted honey in such a market. In producing extracted honey you must sell twice as many pounds, while you can get only half as much per pound. Where the market is limited, the result is evident.

I wish, in another article, to tell of my "combination system," in which the production of extracted honey is so combined with that of comb as to get rid of many of the shortcomings and annoyances that are met when working for comb alone, at the same time producing the choicest extracted honey.

Dayton, Ill., Aug. 25, 1887.

J. A. GREEN.

Thanks, friend Green. I should deem the above a very fair consideration in regard to this complicated and very important mat-

ter. By all means, tell us about your combination system.

REPORTS ENCOURAGING.

20 CTS. PER LB. FOR A TON OF HONEY.

A GENTLEMAN of this State by the name of Chas. McGee has lately received 20 cts. per pound for his honey that he sent off to a commission house. How will that do for prices? He had about a ton, I understand, of white comb honey, all closed out at once. I intend to ship them immediately 25 or 30 hundred of comb honey. I will not give you McGee's or the firm's address this time, for fear too many might rush in their honey at one central point, and lower prices. I will later, if wanted. E. L. WESTCOTT.

Fair Haven, Vt., Sept. 6, 1887.

Your letter is encouraging indeed. It is well that you and your friend did not try to rush off your crop as soon as you secured it. We are bound to have good prices, at this rate.

70 LBS. PER COLONY.

I have averaged 70 lbs. of honey to the swarm, spring count, from basswood. I have not got any honey from any thing else, on account of the drought. At present I have 90 colonies.

Kickapoo, Wis., Aug. 20, 1887. G. W. WILSON.

14 BARRELS OF HONEY.

We have had a very bad year for honey here. The spring was too dry. The first honey-flow we had, to amount to any thing, began about July 1, and lasted until August 15th. I have extracted about 14 barrels of honey.

4—F. S. ELDER & BRO., 112—120.

Lake Village, Ark., Aug. 24, 1887.

27,640 LBS. OF HONEY FROM SENECA COUNTY, NEW YORK.

The Seneca Co. Bee-keepers' Association met Aug. 27th, to compare notes and give in reports. Number of colonies given, 1540; number of pounds of honey, 27,640; for sale to date, 20,000 pounds. All bee-keepers but one report less than half a crop. The honey is mostly in 1-pound sections.

GEO. LAMOREAUX, Sec.

North Hector, N. Y., Sept. 10, 1887.

1668 LBS. OF HONEY FROM 11 COLONIES, SPRING COUNT.

I put eleven hives in the cellar last fall. I took out in the spring, the same number, all strong. I increased to 32, two of which are artificial swarms. I extracted 1668 lbs. of white honey, and sold it all for ten cents per pound around home. There was no buckwheat honey, the weather being too dry. My hives are all shaded with grapevines, on the A. I. Root style.

GEO. SLOASON.

Hawkesbury, Ont., Can.

Well done, friend S. It does us good to see a report like yours, after such a season as we have had. Was there any one else in your locality who did as well?

IS A POOR SEASON ALWAYS FOLLOWED BY A GOOD ONE? THE ITALIANS "A THOUSAND MILES AHEAD."

The season of 1887 will no doubt be remembered by a great many bee-keepers as one of the poorest

ever witnessed. I have watched the reports given in the bee-papers with much interest; and with a very few exceptions the reports are discouraging. There was plenty of white clover, but it has not yielded honey. Red clover yielded bountifully. Basswood yielded scarcely any thing. The colonies at present are nearly at the starvation-point. The average yield per colony in this locality has never been less, up to this time, for years. Honey, too, is not of as fine a quality as usual. Sections filled slowly never have as fine an appearance, and weigh less, than those filled rapidly. I am not discouraged yet, even if the season of 1887 was a poor one. There is always a good season following a bad one. There is always a chance for success. The question of Italians or blacks has turned itself right side out again, and will likely open the eyes of some. This slow season has left the blacks a thousand miles in the shade. The Italians have stored some surplus, while the blacks have scarcely got a living. I can truly say, that the justly praised Italians are, in my apiary, far ahead of the common bees. They can be handled without smoke, at any time, and they are good protectors of their homes.

Douglas, O., Aug. 5, 1887.

FRED LEININGER.

REPORTS DISCOURAGING.

WILL HAVE TO FEED BACK.

B EES in this vicinity have done very poorly this season. I have heard of very few swarms, and little or no surplus honey. We have had only one swarm, and it came off late. It has not yet made enough honey to keep it till cold weather. The white-clover crop was good as long as it lasted, but the dry weather cut it short, as it did most other crops. We took from 30 to 50 lbs. of white-clover honey per colony from some of our hives, but we shall have to give it all back and buy sugar besides, for I do not think we have a colony that has enough honey to winter. Some have none at all. If other bees are no better off for stores than ours, and there should be no feeding done, I believe two-thirds, at least, of the bees will starve before spring. GLEANINGS is a good paper. I could not well get along without it. The imported queen we purchased of you last spring is a good layer. Her bees are as gentle as any we have.

LEVI J. RAY.

Xenia, O., Aug. 21, 1887.

150 LBS. OF HONEY FROM 55 COLONIES.

Crops all burned up here. Bees have gathered enough to winter on, and I have taken 150 lbs. of honey from 55 colonies, spring count, and had 10 or 12 swarms. We may get some fall honey yet.

Muncie, Kan., Aug. 8, 1887. JAS. A. NELSON.

HONEY CROP NON EST.

The honey crop this season here has been, practically speaking, non. I shall have to feed the most of my bees. I know a man who keeps 110 colonies about four miles from here, who got less than five hundred pounds surplus this season, and he isn't a beginner either, having grown gray in the bee-business. He delights to talk of that grand old mark, Mr. M. Quinby. He is, in fact, one of the old Quinby school. What a delight it is to spend half a day in company with him, sitting under an apple-tree over-

looking the apiary, drinking in the knowledge as it falls from his lips! It would be amusing for one to listen to our arguments on the black vs. Italian bee. He keeps blacks, while I endeavor to keep the pure Italians. GEO. SHIBER.

Olean, N. Y., Sept. 9, 1887.

DROUGHT IN CUBA.

Those that have suffered in consequence of the drought in the U. S. are not alone in misfortune, for we have had, and are still having, a most disastrous dearth of honey. I thought last year the worst I had seen since I had been on the island, but this beats last year. We shall lose a great many colonies—just how many I can not tell. Such is beekeeping in Cuba. A. W. OSBURN.

Havana, Cuba, W. L., Aug. 20, 1887.

600 LBS. OF HONEY FROM 40 COLONIES, SPRING COUNT.

I commenced this spring with 40 colonies. I have now 96, and only 600 lbs. of surplus honey. The most of my bees are in good condition for winter. It has been very dry all summer. Basswood was good about a week. My bees are Italians, hybrids, and blacks. I have watched them close for 3 years. The Italians come out behind. This year has been their favorite time. A hard year, it is said, Italians work when others lie still, but this year they have not given me a pound of surplus. They are nicer to handle, but I can not keep bees for the fun of it, in my old age. I have just visited two other apiaries of 140 each. They told me their hybrids were their best honey-gatherers. J. B. WHEATON.

Ithaca, Gratiot Co., Mich., Sept. 6, 1887.

MELISSA, OR BEE-BALM.

The first of June found me with 62 swarms of bees, in fair condition for securing the honey crop. The clover bloomed, but gave very little nectar. Time passed on, with an addition of 20 swarms and no surplus honey stored to this date, Aug. 22. Our late rains have revived vegetation, and the clover is sending out a second bloom, and the fall bloom is revived, and we are in hopes the bees will yet gather enough to winter on, if no more. I have had a little trial with melissa, or "bee-balm," this season. It commenced blooming the fore part of July, and still is in bloom. I think it will continue until frost. The bees are on it from morning until dark. I think it is superior to all other honey-plants that I have ever seen. C. M. BLISS.

Fox Lake, Wis.

POOR ENOUGH.

If you will accept a report from me, though very discouraging, I will give you a few facts. From April 28 to May 30 the weather was alarmingly dry. There was but little honey from apple-bloom; clover, none of any account. There was a good flow from locust. Basswood we have but little of. June, July, and August have been so wet that crops have been damaged to a great extent. Black bees gave me 34 lbs. per colony; hybrids the same.

All colonies are strong in bees, but there is no surplus. Black blood is preferable for me in my locality, though hybrids are my choice. Bees wintered badly generally. Mine did fairly. I lost 6 out of 34. Some lost about all in chaff hives, well packed. Severe March weather did the work. Buckwheat honey is coming in now well, and there is a prospect for fall bloom. I have taken from

59 colonies, 400 lbs. of comb and 100 of extracted. Poor enough. GEO. A. MATHEWS.

Katonah, N. Y., Aug. 28, 1887.

NOTES AND QUERIES.

SHALL THE BROOD-NEST BE DISTURBED?

MY lower stories are full of honey and brood. Would you let it all remain for winter, or remove all but 3 or 4 frames?

D. O. MCCAMPBELL.

Harmontown, Miss., Sept. 8, 1887.

[It depends entirely on the amount of bees to be wintered, friend M. If it is a powerful colony of bees, leave the whole entire lower story. If an ordinary colony, say 5 or 7 frames; if not up to the average, perhaps only 3 or 4 frames, as you suggest. And, by the way, a powerful colony will winter about as well just as they are, as any way you can fix them. See discussions in regard to this matter in our back volumes.]

CELLAR WINTERING.

I am putting a cellar under my house. It will be completed about Sept. 20. Can a few colonies of bees be wintered successfully in the cellar the following winter? MERRIT BALDWIN.

Steamburg, Pa., Aug. 30, 1887.

[Yes, if your cellar is dry you can winter a few colonies successfully; that is, if you carefully observe the conditions required for cellar wintering. You will do well to read some of C. C. Miller's recent articles on the subject. See also "Cellar Wintering," in the A B C of Bee Culture.]

DEAD BROOD.

What is the matter with my bees? I have four good strong stands of Italians, with nice young queens, and they are all uncapping their brood when it is about 17 or 18 days old. Some of the brood is turning black. Whether they are all dead or not, I do not know, but they are motionless. They have all got plenty of honey to winter, but scarcely any surplus. A SUBSCRIBER.

[I should judge you have what is called "dead brood" in your hives. Brood that has been neglected, or subjected to conditions unnatural to its growth, will die, and has a gray-black appearance.]

WHAT ARE THE INDICATIONS, IF ANY, THAT A QUEEN WILL BE SUPERSEDED?

Will some of our veteran bee-keepers give your readers an article on why bees supersede their queens, and how to tell when bees are going to supersede a queen? I have read for years the various journals, and never saw a really concise and good article on this subject. Many a fine and prized queen has often been lost in this way—"unexpectedly missing," and it would be a real service to your readers to know more about this important subject. A BEE-KEEPER.

HOW TO MAKE A TESTER FOR HONEY VINEGAR.

I am making honey vinegar. For a test I have tried to use the egg, and the ball of wax with shot inside, without satisfaction. How to get the shot inside is a puzzle, as the apple dumplings were to King George, who was fond of the dumplings, but could not imagine "how the apples were got in." I find it better to eat the egg, and pour melted wax into one half of the shell. In the ball thus formed, stick three wire nails, another in the top to lift it by. Mix some water and honey, 1 lb. to the gallon, and try the tester. D. F. SAVAGE.

Hopkinsville, Ky., Aug. 19, 1887.

BEE BOTANY, OR, HONEY-PLANTS TO BE NAMED.

HERCULES' CLUB—A BEE-PLANT.

PROF. COOK:—In looking over your "Bee-Keeper's Guide," tenth edition, I can find no description of the inclosed honey-plant, which is plentiful on the bluffs of Lookout Mountain. It has just come into blossom, and is worked on freely by the Italians, but not by the smaller common bees. The tree or shrub grows to 10 or 12 feet high, has a thorny trunk, the limbs and flower-stalks branching out at the top of the trunk, like a palm-tree. Sourwood is very plentiful here; and as this tree blossoms just as the sourwood ceases to bloom, it may be of value, providing the quality of the honey is good; but it is such a queer-looking tree or plant that I am doubtful about it. Can you tell whether the sourwood grows from the seed, and whether it can be grown as far north as Maryland and Ohio? It is a beautiful tree, and yields bountifully of beautiful white honey.

DR. C. F. PARKER.

Valley Head, DeKalb Co., Ala., Aug. 15, 1887.

In reply, Prof. Cook says:

Friend Root:—The plant referred to above by Dr. Parker, of which he sends the leaves and fruit, is the curious Hercules' club—*Aralia spinosa*. This tree grows along river-banks from Pennsylvania south. We have it growing on our grounds here at the Michigan Agricultural College, so it is quite hardy. It grows from 6 to 20 feet high. The bare trunk is armed with strong spines, and, like the palm, is crowned with great leaves with ovate-serate leaflets, among which are the flowers.

Mr. P. asks about the quality of the honey. The bees work freely on the flowers here—are even now, Aug. 25th, at work on them; yet as we have only a few of the trees I can not speak of the honey. Can not Dr. J. P. H. Brown, of Augusta, Ga., tell us of it? Mr. Parker says of this plant that it comes into bloom just as sourwood is going out. He also asks if the sourwood, or sorrel tree, will grow from the seed, and whether it will grow as far north as Michigan and Ohio. I answer yes, to both questions. We grow it here, though, like the peach, which it somewhat resembles, it "kills back" in severe winters.

A. J. Cook.

Michigan Agricultural College.

BEE ENTOMOLOGY,

Or Enemies of Bees Among the Insect Tribe.

BARK, OR SCALE LICE, AND RED SPIDERS.

PROF. COOK:—Inclosed find some leaves which are covered with insects, which please examine and tell us what they are and what will exterminate them. HENRY DUNHAM.

Nashville, Tenn., Aug. 18, 1887.

Prof. Cook replies:

On the leaves sent by Mr. Dunham, Nashville, I found scale-lice and the little mite known generally as the "red spider." The scale-lice were the immature forms of the bark, or scale-lice, which were so common a few years ago all through the North, and which so injured the trees, and which secreted the nectar which so annoyed the bee-keepers. For-

tunately for our beautiful shade-trees, and also for our bee-keeping industry, numerous insect-enemies attacked them so vehemently that they were vanquished, and our trees saved. I found that the kerosene-and-soap mixture would kill these lice. It was made by mixing a quart of water, a quart of soft soap, and a pint of kerosene together, then stirring all vigorously till they were permanently mixed. This is easily done by pumping the liquid by means of a force-pump back into the vessel containing it. We then dilute so that we shall have one part of kerosene to ten or twelve of water. This may be sprayed on to the trees just as the eggs hatch in July, or the limbs of the trees may be washed with it late in the fall or early spring, when the lice have migrated from the leaves, and are sapping the branches.

The "red spiders" are often very serious enemies in very dry seasons like the present. They spin a web on the leaves. Frequent drenching of the plants with water will kill them. A. J. Cook.

Agricultural College, Mich.

I presume, friend Cook, the red spider you mention is the same one that troubles florists so much in their greenhouses. I believe, however, that Peter Henderson states that it is caused by having the atmosphere too dry. If this is the case it is easily managed in the greenhouse; but during a dry season like the present it would be a pretty big job to drench "all outdoors" with water. I did not know that the red spider ever made trouble in the open air.

THE SPINED SOLDIER BUG, AGAIN.

An Indiana subscriber to GLEANINGS sends me several of these very useful hemipterous, with the request that I describe them and give their habits.

This bug is about the size of the "bee-stabber," described in GLEANINGS for Aug. 15. It is common all over our country; and as it is a ravenous feeder and lives almost wholly on insects that injure the farmer and gardener, it does immense good. I have never heard that it attacks bees, and I hope it will be long before it forms such a habit. I shall be pleased if any reader of GLEANINGS who may have seen it about bees will tell me if he has seen it mo-

SPINED SOLDIER BUG.

lest his pets of the hive. The figure I send will give a good idea of this bug. Its scientific name is unusually appropriate—"spined soldier bug;" spined, from the spines on the thorax. These sharp spines will enable one to identify this bug. The color is gray to brown. The jointed beak shown in the figure is a most interesting weapon. Within are some long slim needle-like organs which can be forced into its prey. These so wound the unfortunate victim that the blood oozes out, when, by the use of the large grooved labium, or the jointed beak, this nutritious liquid is sucked up. All of these bugs have the same style of mouth parts—a large grooved sheath which conceals the sharp strong needle-like piercers.

A. J. Cook.

Michigan Agricultural College.

WHAT TO DO, AND HOW TO BE HAPPY WHILE DOING IT.

Continued from Aug. 1.

CHAPTER XXXIX.

For in the wilderness shall waters break out, and springs in the desert. And the parched ground shall become a pool, and the thirsty land springs of water.—ISA. 35: 6, 7.

GOD'S GIFTS.

It has always been an intensely interesting subject to me to look about me and see what God has placed within our reach, that we have never yet discovered or developed. It is for this reason that I have always been deeply interested in mining for coal and the useful metals; and when the oil excitement broke out some years ago, the news of the treasures to be found by drilling down into Mother Earth naturally thrilled my being with intense interest. In the same way I have been interested in the developments of natural gas. But I believe that natural gas and oil are by no means all that nature has in store for us, lying hidden beneath the soil of our hills and valleys. In fact, I do not believe it is well for every one to start out in the oil or gas business. "Every man to his trade" is a good rule here as in most other things.

For some years back I have been studying hard on the problem of water for irrigation during our dry spells which occur to a greater or less extent every season. A little over a year ago I was enthusiastic about saving the rain water that comes so lavishly in the winter and spring. In Chapter VII. I told you about the underground reservoirs for collecting these waters and holding them until needed. Well, the principal trouble with these reservoirs during a protracted drought is, that they become empty, and the ground directly over them dries out even *worse* than where the ground is simply underdrained. I do not believe we can store water profitably for six months by simply making excavations in the ground; for even a pretty good-sized pond will soak away and evaporate until it is gone, or nearly gone, even without drawing on it for irrigating purposes. Our carp-pond would hold perhaps 5000 barrels; but during the recent drought, even though none of the water was used for the purpose mentioned, the water has disappeared until the fish would like to have perished had we not brought a reinforcement of water in the way I am going to tell you of. Now, another thing is to be considered in this problem of storing up the waters from the rain and snow until they shall be needed. An immense reservoir is required. To water an

acre of ground properly would require, say, 500 or 1000 barrels of water every two weeks; and to store this amount for even three months' time would require a cistern or reservoir beyond the reach of even most of our market-gardeners. In favorable localities, very likely the water might be dammed up by a pond; but few are so situated as to avail themselves of this.

The next feasible plan would be to make use of running streams, and this is already being done to a great extent, especially in the western parts of this country, and the area thus irrigated is being rapidly enlarged year by year. Not only streams, but rivers, are utilized entirely in this way. No great reservoirs are needed, because the moving water furnishes the supply day by day as fast as it is consumed. Along the Rocky Mountains the melting snows furnish unfailing streams. Many of our readers are familiar with the method of irrigation; namely, running the water in a furrow until the ground is irrigated, say for four or five feet on each side. At Arlington, Mass., I saw friend Rawson turning water between every other row of celery. When the ground was sufficiently wet in one furrow, the water was turned into the next, and so on. Well, comparatively few of us have unfailing streams that flow on a level, higher up than the ground to be irrigated, therefore this plan can be utilized only in certain favored localities. Then again comes the question, "What shall the rest of us do?" In many localities, springs on the hillsides, or at the foot of the hillsides, furnish large amounts of water that are allowed to go to waste year after year, because nobody has yet had sufficient energy and enterprise to recognize them as God's gifts, and make use of them. A neighbor of mine, a few miles away, had for years a spring on a hillside, that annoyed him by spoiling a great part of one of his best fields. In accordance with a suggestion from myself, however, he arranged it with very little labor so as to run between every alternate row of his cabbages. He constructed a little pond which filled up during the day time, and at nightfall the contents of this pond was let loose so as to pass down be-

tween two rows of cabbages. At the very first trial he succeeded in getting a splendid crop when cabbages were a failure everywhere else. How I have often longed and wished for a spring like friend Green's! But ours is a clay soil, and no sandy hills or great rocks are in our vicinity to make it even probable that such a spring was to be found. Year after year I longed for a spring; but although I had carefully scanned every foot of ground that we called our own I could think of no way to get water from that source. The matter was, however, very much on my mind; and although I often thanked God for the gifts that had been discovered on our ten acres of ground, I had never yet quite faith enough to ask him to give us a *spring*. I had, however, often come around to the conclusion that a spring that would give even a slender stream of water continuously and daily would be worth more than a great reservoir to hold the waters that come sometimes with such superabundance.

When I first came on our grounds I noticed that the stream we call Champion Brook occupied perhaps ten times as much ground by twisting back and forth across the lot as it would if made to go in a straight and narrow channel; therefore one of my first projects was to cut this straight and narrow channel, from the point where the stream enters our lot, to a culvert under the railroad where it escapes. Now, this culvert, although it is large enough for a two-horse wagon with a big load on it to drive through, at certain seasons in the year, during heavy freshets it was in the habit of getting filled up so the water covered several acres of my low ground; while during dry seasons like the present one, Champion Brook is nothing but a dry bed of stones and gravel. Just now I suppose you might follow up this bed a mile and not find enough water for a cow to drink. So you see the great amount of water that does so much damage at one season affords us no relief at another. By making this straight channel, however, so as to shoot the water perfectly straight toward the culvert, I found that it passed through so much more rapidly that there has never been a back-up since it was cut through, unless it was caused by the ice; and at such times a couple of men with poles can stop its damming up, even then. I want to say to you right here, that if any of you have similar plans of making a stream go straight through your lots, don't fall into the error that I did, and imagine

that you must dig a channel wide enough and deep enough to carry *all* the water. Let Nature do the work in this way: First cut a ditch, just as you do to lay tile, in a perfectly straight line, where you want the channel to be. Make this ditch deep enough to *start* the water through it, and no more; then dam up the old channel and all the low places along the margin of your new water-course, so as to force all the water that passes, to go in the new channel. Now keep an eye on it, and after every freshet dig out and dam up and repair, and pretty soon Nature will have formed the channel at a comparatively small expense. Of course, you are to assist Nature by deepening it over hard spots of clay, or by cutting out stones, until you have a regular slant from where it comes on to your land to where it goes out. When there is very little water running, watch the ripples and you can see where there is too much fall and where there is too little. Get some old-countryman who is skillful with spade and pick, and he will fix it nicely for you. The sides of the bank should be just sloping enough so it will not cave in. The idea is, to have them sod over eventually, and this will keep your channel where you want it. If in cultivating crops your rows run toward this ditch or channel, you can make the bank sloping enough so that the horses, in cultivating, can walk down the slope and have your turning-around ground along this slope. This utilizes room, and such a slant will not cave in, especially if you keep the bottom cleared out. The sides of the ditch should be something like the sides of a letter V. Perhaps you had better have enough room on the bottom to make a comfortable footpath in dry weather. Well, last spring, in my anxiety to save my crops from a freshet, I directed Mr. Walker to clean it out and make a very nice straight channel for the water to run in. Along a good part of the stream he went down to the rock, or a sort of slate or shale. In order to get a regular fall I directed him to cut into this rock with a stone-mason's pick, and he did it so nicely that it became a favorite place for the children to play, on this clean rocky bottom.

Some time in July it became evident that a planting of celery would die unless we watered it. We did not want to take the water out of the carp-pond; and as none was running in the creek, we decided to scoop out what we could in the low places. There was one spot in particular where

there seemed to be quite a little water; and one of the boys told me that it ran in there as fast as they scooped it out. I noticed something of a depression, and asked Mr. Walker if he didn't find the rock there. He replied that he did not — at least, nothing hardly solid enough to be called a rock. It was a sort of blue clay that could be whittled into fantastic shapes with a knife. In fact, there is now on our mantelpiece a little Bible that I carved out with my penknife, of soft shale, and the children had often amused themselves by carving figures of this material. Well, when Henry told me that the water came in at this spot as fast as they scooped it out, I pulled off my shoes, waded in, and took the pail. I ladled it out for the boys while they passed it to others on the bank. The bottom of the cavity seemed to be softer and softer as I scraped it with the edge of the tin pail. Finally I scooped through into some beautiful yielding gray and white river sand, apparently, and out of this sand was water springing forth, something in the language of the text — "For in the wilderness shall waters break out, and streams in the desert." Our garden was looking very much like a desert just then under the influence of the scorching July sun. When they got all the water they wanted I scooped out the sand, and threw it on the banks of the stream, then threw the surplus water away down stream until I stood in a little well, perhaps two feet deep. By holding my pail up near the side whence the water flowed out of the sand, it was filled up quickly. I was afraid it could not be true; that is, I hadn't faith to believe that it would hold out. Again and again I filled it. Finally I pulled out my Waterbury watch, even though my fingers were somewhat muddy; and while I timed the filling of the pail, my hand fairly trembled with excitement. There was no mistake about it. God had given us a spring, and one that poured forth beautiful pure water at the rate of a three-gallon pailful a minute. How quickly the figures began to run across my mind's eye — 3 gallons a minute is 180 gallons an hour; and calling 30 gallons a barrel, we have 6 barrels during every hour of the 24; 144 barrels of water in a day! Can it be possible! A large iron tank was brought and placed on the bank on the side of the creek. A new pitcher pump which Ernest had purchased to put in his new house was brought down and screwed to an iron pipe. Then Henry mounted a dry-goods box on the bank, and

worked until the tank was full. As the spring showed no traces of giving out, a piece of hose used in our greenhouse was procured; and by folding one end over the tank so as to have a siphon, we soon had a stream of living water flowing between the rows of celery. As we had already been waiting some weeks for a rain, that we might put out some celery-plants, we decided to wait no longer. One of the boys, with the wheel-hoe before mentioned, made some nice little furrows very quickly. With the hose we then carried the water to the highest point in the furrow, and let it flow both ways. When the furrow was pretty well soaked its whole length, our plants were set out; and although the burning July sun blazed right on to them, they took hold and grew as well as any celery-plants I ever saw. The merits of spring water were well established. Henry found, however, that he could, with his pitcher-pump, draw more than a pailful a minute, so that a beautiful live spring was seen bubbling forth in that hole I had scooped out in the creek bottom. The boys were by this time in full sympathy with the experiment, and the quicksand was scooped out until the whole rock was found, perhaps a foot below the clay. Into this rock we chipped a hole perhaps a foot deeper, and now we had about *two* pailfuls of water a minute; and, best of all, when the pump stopped working, the cavity speedily filled up, and living water was flowing forth down the heretofore dried-up channel. When our proof-reader, Mr. W. P. Root (who is also organist during our noon meeting), asked me to look into the 35th chapter of Isaiah for something to read for our noon service, I was almost startled to find these words: "And the parched ground shall become a pool, and the thirsty land springs of water." Here was the water, and all that was needed to get it was to scrape the bottom of that old dry channel with nothing but a tin pail.

I had not dared to ask God to send me a spring where there were no indications that there might be one; but in his loving kindness he has given us something we did not even ask for. He knew I wanted it, however, and therefore he gave it; but it was, as I believe, because he expected me to make good use of it. One of my neighbors hearing of it, came down to see the spring we were rejoicing over, and said that his cows were out of water, and he had just been wondering what he should do. Through his farm ran a creek just like

mine; and on getting down he found the same kind of quicksand, and water in abundance. Investigation on different points along our creek showed no less than a dozen similar springs, but none that gave the quantity of the one I have mentioned. This subterranean vein of quicksand varies in thickness at different points, and doubtless extends off under the hills in many directions if not in all directions; and after much study and investigation I am inclined to think that this water is held in the sand and gravel only by a sort of capillary attraction. Here is the reservoir that we could not afford to make, made already by the finger of the great Father himself; and instead of holding *thousands* of barrels of water, it no doubt contains *millions*. All that is necessary to get the water is to create a cavity or vacuum, and the water rushes in. When the stream of pure water came out of the sand and rock, and flowed down toward the tube connected with the pump, I ran up to the house and summoned mother and all

the children. Constance (the one we called "Blue Eyes" for so many years) is now a big strong girl of fourteen, and she is just beginning to take quite an interest in these things that have made me happy for so many years. When I explained that this bed of sand and gravel probably went away up under the hill, and may be under our house and factory, she made a remark something like this: "O pa! I do so want to see what is *inside* of the hills! I want to see the springs and the rocks."

"Well, my girls, I am very glad indeed to see you anxious to know more about this beautiful earth that God has given us. I have been long thinking of taking you on a trip to see the home of my boyhood, amid the springs and hills of Summit County. If mother approves, we will take Meg and the buggy and go off for a holiday, starting after dinner."

At this, Caddie joined in with Constance, and they could hardly keep still until the time arrived to start.

CHAPTER XL.

He looketh on the earth, and it trembleth: he toucheth the hills, and they smoke.—PSALM 104:32.

The memory of that three days' visit with the children will always be a pleasant remembrance. How thoroughly I got acquainted with them during these few days, when we three were so much alone together! For several days afterward I caught myself feeling lonesome without them.

Now, then, in regard to the hills. We passed the first night at the old homestead where my mother's father first located in the woods, years ago. A part of his first purchase included the highest hill in the vicinity round about there; and I told the children the night before, that, if they would get up early enough, we would go up and see the sunrise from the summit of grandpa's hill. Now, grandfather Hart had a great taste for natural science, although he had no modern advantages in the way of education, and this great hill had been for years a hobby of his. While we stood on the summit of that hill the next morning, taking in the beautiful scenery spread out before us as it was lighted up by the morning sun, I told Caddie and Connie that it was nothing strange that they, in

common with myself, should want to know what is inside of these great hills; for the very blood in our veins was that which stirred grandpa, perhaps fifty years ago, to want to know what was inside of this great hill. In fact, fortune-tellers got hold of the idea that this hill was his hobby, and one after another offered to tell, for a certain sum of money, what was hidden beneath its lofty summit. I remember an advertisement that appeared in one of the papers somewhat later, of an instrument called a "goldometer" that would tell whether gold or other valuable metals, or even coal, was hidden in the earth beneath. Grandfather sent two dollars, but that was the last of it. When I told the girls that he became so curious that he made investigations into the hillside, they were impatient to be led to the spot. Then I took them to a little mound, or grassy knoll, off a little to one side, where for years there had been a single little grave. Years before I was born, a little child named Amos, in climbing up to get something from the mantlepiece, fell with his face into a kettle of boiling maple syrup.

He lived several days afterward, but most of the time was calling plaintively for water. When he died, as they were far away in the woods, a lonely grave was made on the spot where we stood; and when I told the children that their papa was named after this little one, a sad and solemn look came over their faces. Cousin Ray then piloted us to another spot on the slope at the foot of this great hill; and after he had pulled off a lot of brush and sticks from a cavity in the ground, he took hold of an iron ring and began to pull. I thought of the stories in the Arabian Nights, and wondered if some genie was going to raise up and tell us about the gold or silver, or, possibly, even commonplace coal that lay hidden beneath this old mountain, as it seemed to be, almost, in our eyes. Well, the lid came up and we peered down. We did not see any genie, however, but only the reflection of our own faces in a beautiful cool spring that bubbled up in the bottom. I notice in Summit County, that where springs are found, of late years, they use a great many tubes made of stoneware, to place over them. These tubes are like a great stoneware crock without any bottom, and many holes are made through the sides, to permit the water to flow in. About half way to the bottom of this spring a pipe came in it through the side of the stone crock; and over the end of this pipe was a tin can pierced with many holes. A few rods further down the slope we came to the lane where the cattle and horses go to pasture. The pipe that came from the spring poured into a trough that ran under a fence so as to water the stock in two different lots. From this trough it poured into a second trough that stood in the lane. A tin cup hung on a post, and from this tin cup we took draughts of cool spring water—the veritable soft water of the springs of Summit County.

Grandfather did not find any gold in reward for his investigations, by digging into the hillside; but I told Uncle Ben's folks I should consider that spring worth more than gold or silver or coal either, if I had it. After the water poured out of that last trough it ran under a bridge, and then down into the pasture lot. For *sixteen years* it had been running right on that one spot. Did it cause a great luxuriance in growth over the other grass and weeds in that field? By no means. Let me tell you, my friend, if you don't know it already, that pouring water on to a piece of ground continually, day after day, *won't* make things grow. In fact,

all this spring did to this pasture lot was to make a mucky swamp where the cows got mired if they attempted to go across or through it. To make things grow you must saturate the ground and then let it dry out. When sufficiently dry, saturate it again, and so on. This rule applies to flower-pots, window-gardens, dooryards, and every thing else where we practice irrigation. Nothing but swamp-weeds or genuine water-plants will grow where it is constantly wet. Close by this swamp-bog formed by that spring was a great lot of rich sheep-manure, for Uncle Ben deals largely in sheep and cattle, buying and selling them by the carload. I tried to get my cousins, Ray and Judd, interested in starting a celery-garden where that spring was spoiling the ground; but although Nature had placed every thing so very handy and convenient, there it lay year after year, untouched and unused. Why, I almost felt as if I must take off my coat and show them what could be done with that spring of water.

Before night I found there were hundreds of other similar springs all over Summit County, doing that very same trick—running down the hillsides, making swamp-bogs, and doing no good to anybody. I did rejoice to find one gentleman, a friend of our bee-journal, by the way, laying under-drains to get rid of this surplus water, and I believe he proposed making a garden. There it was on my old homestead, right where I used to make garden thirty-five years ago, and I had thought of that spot, with its wealth of spring water, time and again during these years that are past. I have not time here to tell you of the springs we found on that trip; but some of them pour forth water enough to run quite a water-power, and yet they do nothing, winter or summer, more than to water the stock.

Another relative, in Tallmadge, has brought a spring down a hill, and up again to his house on the opposite hillside. Here it gives a constant stream for the use of all the household. Then it goes to the barn, and fills a large tank where the stock can drink every day in the year; and after that—now, what do you suppose it does after that? Why, it just runs off on the ground, and has done so for years, doing no good to anybody. Where it leaves the kitchen it is on higher ground than the kitchen garden; and although the kitchen garden suffers just like other gardens, from the lack of rain, nobody has yet ventured to turn this surplus water between the rows of vegetables.

At Mogadore (Summit County) I had an opportunity of satisfying Connie's desire to know what there is inside of these great hills. The railroad company had purchased one of the largest of them, just for the gravel; and at the time we were there they had taken off just about half of the hill, leaving the strata of sand, gravel, and occasionally clay, plainly visible. But a richer treat awaited us in a sandbank belonging to my nephew, who lives on a hillside. He, too, has grandfather Hart's blood in his veins, and has also inherited a disposition to want to know what there is in the hills. Like grandfather of old, he was not satisfied until he had dug a hole in the side of his hill, and there he found the most beautiful, clean yellow sand. This particular hill has also strata of sand, gravel, clay, etc.; and here the strata seem to curve with the curve of the hill. In fact, the different layers are much like the layers seen in cutting into an onion. But there is something stranger still about it: Near the convex surface of the top of the hill the layers seem to have been separated by some convulsion of nature, so as to leave cavities, or pockets, if I may be allowed the term. Now, the beautiful sand he found was between the strata, within these pockets. Near the summit of the hill the vein was perhaps two feet thick; but it curved downward toward the valley until it disappeared in a sharp edge. The diagram below will illustrate this plainer; and if you will use your eyes at the first opportunity, you may glean many wonderful facts in regard to the formation of this earth upon which we live.

SECTION OF HILL AT MOGADORE, O.

My nephew is also something of a market-gardener, and his celery, cabbages, etc., were suffering from the lack of water, like those of the rest of us. I assured him there were springs at the base of this strange hill, for I thought the spring water must be conducted along through the different strata. He insisted there were no springs high enough up to take the water on to his garden. At the foot of the hill was the usual muck swamp which we find so frequently in Summit County. I pushed down among the bogs, and found a ditch he had been cutting through to get rid of the surplus water.

"Why, look here, Homer. You surely have springs that furnish the water for this ditch."

"Why, no, Uncle Amos. You see the ditch is now about all dry. See here; there is not a bit of water running."

"But, my young friend, will you please to look *here*?"

I showed him that, a few rods below where he stood, there was quite a good stream of water. And, by the way, I have several times found springs by following up ditches or runs. When you find running water in one place, and none a distance above the spot, you have got track of a spring. Pretty soon I reached my hand in a hole in the bank, and out came water enough to fill an inch pipe. He promised to follow it up to its source, and see if he could not find it high enough to turn on to his garden; and I am quite sure that many of you, my friends, may find springs on your own land, if you will search diligently.

In visiting the Glen, at Cuyahoga Falls (Summit County), we had another wonderful lesson in regard to the interior of the earth. The Cuyahoga River has cut through the soft sandstone, in some places to a depth of several hundred feet; and the straight walls, as they rise up, reveal to human eyes the wonderful rocky structure of old Mother Earth. Strata and pockets are visible here without number; and in one place a thin layer of brown rock has been crimped by some convulsion in former years, so that it has lapped over on itself, like the figure shown below.

KINK IN A STRATUM OF SANDSTONE, TO BE SEEN AT CUYAHOGA FALLS, O.

Now, after this crimping, or doubling-up, the great rocks settled down so as to flatten it down all solid together; but it is plainly evident by the grain of this curved strata, that it was formed by some great convulsion at some stage of the formation of these wonderful rocks. From many of the strata, beautiful springs flow forth; and one great overhanging rock sends forth so many of them that it has been aptly named "Weeping Rock."

In the afternoon we stopped at the house of a Mr. Babb, a mile or two west of the town of Cuyahoga Falls. The bottom of Mr. Babb's cellar is cut into the solid sandstone that comes clear to the surface of the hill whereon stands his beautiful dwelling.

In the middle of the cellar a square hole is cut in the rock, perhaps a foot deeper than the stone cellar floor. Into this cavity a stream of soft water flows, which I should think capable of filling a two-inch pipe. The cool water passes around their milk-cans, forming a sort of spring-house, and then it comes out into the dooryard, where it fills a fish-pond cut in the rock, perhaps 20 or 30 ft. across. Several years ago this little pond was filled with most beautiful speckled trout. The water is constantly moving and constantly overflowing, and this gives the surface a mirror-like brightness that is most fascinating to passers-by. After leaving this reservoir the water pours in a series of waterfalls down a rocky gorge. As we started along with Meg and the buggy I ejaculated, "O children! here is a hydraulic ram."

"Why, where is a hydraulic ram, pa? and what is it? Where do you see it?"

I was obliged to say that I didn't see it at all; and then came the question, "Why, pa, how can you say, 'Here is a hydraulic ram,' when you confess you don't see it, and have not seen it?"

I told them that, although I had scarcely ever seen one in my life, I knew the clicking sound, or the series of thumps, or, perhaps more correctly, pulsations, we heard, were caused by a hydraulic ram; and in a moment more there it was by the roadside.

HYDRAULIC RAM, FOR ELEVATING WATER.

There it stood, all by itself, but yet hard at work, and it was to me a thing of life and beauty. It made the water fly and spatter; but in doing so it pushed perhaps a fourth of the whole stream away up to the top of a hill, and poured it into a tank over the fence, for the stock to drink. Besides this, it sent it up into a great bank barn on the hillside; and, in fact, it pushed it up hill and down, wherever it was wanted, over that hilly farm. At one time I felt quite sanguine about carrying my spring water by a hydraulic ram; but when I told the manu-

facturers that I could not get more than a foot, or at most two feet, fall on my premises, they kindly informed me that it would not be best to try to use one. The address of the maker is Allen Gawthrop, Jr., Wilmington, Del. But perhaps many of you, my friends, can make use of this ingenious little machine. I was surprised and pleased to learn that they are now manufactured for the very low sum of only \$11.00.

Well, there is something else that we kept track of during our visit, besides the springs, and it was windmills. They are now dotting the landscape here and there through almost all of Ohio, and I feel like thanking God whenever I see one. I will tell you why. Mrs. Root is a nice cook—at least so they say in our home, and she is rather particular about her materials for cooking. I have told you before how she complained when the boys carelessly gave the cow spinach that had gone to seed—so much so that it was bitter. At another time one of the small boys gave her a lot of onions. Everybody who tasted of the milk after that knew it, I tell you. Well, ever since this dry weather the water in Champion Brook dried up so it stood only in stagnant pools, and Mrs. Root complained again of the milk. She finally insisted that Henry should give the cow a pailful of clean water from that new spring we were rejoicing over so much, as often as the cow would drink it. He did so, and the milk was all right. Furthermore, Bossy showed her preference by coming up to the fence near the spring, and making a fuss every time she wanted fresh water. Well, the windmills scattered over the land indicate nice pure water for the cows; and pure water for the cows means a smaller liability of typhoid fevers and such like diseases that often take away our loved ones during the dry weather of August. I told Connie and Caddie to watch the windmills and see what particular ones ran with the lightest breeze. They soon learned to call them by name, and we noticed certain makes that were almost always pumping. By the time we got home we had decided pretty much what kind of a mill we wanted. Then a lot of letters were dispatched to makers of windmills. I wonder, my friend, if you are as ignorant of the real cost of a good windmill as I was. When one manufacturer named \$36.00 as the price of a windmill, all complete, except the tower, I thought he must have made a mistake; but when others offered them at prices varying from \$38.00 to \$50.00, I felt

like thanking God again that these beautiful machines were at length offered for so small a sum. My plans were pretty quickly matured. When I scooped the water out with that tin pail I noticed a pure silvery stream that came out of the sand and rock. It came from the northern bank of the brook, and a few feet away—far enough to get into the solid ground—Jacob was directed to dig a well. He is a stout German boy, and it is just fun for him to dig. In a little more than a day he had thrown out the yellow dirt, so that he got a glimpse of the blue clay.

As before, we found this blue clay just about one foot in thickness; and when we got through that, that gray quicksand full of water presented itself. The transition from the clay to the sand is so sudden and abrupt that we cut out a great chunk of the clay off from the top of the quicksand. It came off as clean as you would slip the custard from the crust of a piece of custard pie. In fact, I turned the block over and washed its under surface; and when the sand was cleaned away, there was the smooth bottom to the block of clay. Then comes the question, Why doesn't this immense weight of clay and earth sink down into that soft yielding semi-liquid quicksand? I presume the only reason is, that there is no place for the quicksand to go to get out of the way, so the solid earth rests on it, much as it would rest on a body of confined water. This bed of quicksand is perhaps one or one and a half feet through, and then we come to a slaty rock. Jacob dug down into this rock perhaps a foot, to make room for the pump; and as it was then dinner time the well was left. I told the boys to get back as soon as they could, because there would be so much water in the well. In just 30 minutes we were on the spot, and, to my great astonishment, we had quite a well of water. A little figuring revealed the fact that at least five barrels had run in in 30 minutes. Now, 10 barrels an hour would be 240 barrels a day; but we were not sure that the spring would give this amount continuously.

Well, friends, as I write this morning, Sept. 9, the windmill is pumping away, and the carp-pond is partly filled up—at least there is water enough so the fish are rejoicing in it; and it is not stagnant pool water either. It is clear running spring water. The windmill delivers it into a tank close by the well, and this tank is for irrigating the creek-bottom garden. In case the wa-

ter is not used as fast as it comes in, however, a pipe takes the overflow and carries it over to the bank of the carp-pond. Before going to the pond, however, it fills a large tub made of the larger half of a cask or barrel. This tub is for the Jersey cow; and she admires it so much that she comes and takes a big drink whenever any visitors come to see our spring and waterworks.

When the tub is filled nearly to the top with surplus, it pours over into the pond, as before mentioned, and the windmill keeps up a stream of running water, the volume varying according to the strength of the breeze. I do not know that I ever put up any piece of machinery that has given me so much pleasure as this mill. It is the Eureka, manufactured by Smith & Woodward, Kalamazoo, Mich.

Now, for irrigation we need a large reservoir or reservoirs for storing the water during the occasional days when the wind does not blow; and although our well gives us so large a volume, I felt as if I could hardly spare the water in the springs that fill the channel of the brook. This channel, you will remember, is one that is cut straight through the land artificially. In places it is five or six feet deep. Well, by putting some heavy planks across it at the lower side of our grounds, we have dammed the water up so it sets back as far up as the windmill and pump, and even further. Just a couple of plank set in against firm posts, with their joints made tight with the afore-mentioned clay that came out of the well, have given us a reservoir that will hold one or two thousand barrels, at an expense of only four or five dollars; and during a very windy day, when the water is pretty much out of the well, it passes through from this reservoir, through this porous quicksand that I have mentioned; so you see, during a drought like the present one I have a reservoir to draw on besides the capacity of the well. As soon as the children saw this long pond, Huber petitioned for a little boat. The boat is made, painted white, and christened the "Mayflower;" and could you see the children enjoy themselves scudding up and down this canal of clear spring water, you would, I think, agree with me, that the arrangement is worth all it cost to make home pleasant for the children, if nothing further. I used to say I would give \$500 for a living spring on our premises, and here it is pouring forth a steady stream *almost* constantly, at a cost of considerably less than even \$100,

To be continued.

HEADS OF GRAIN FROM DIFFERENT FIELDS.

HOW MANY COLONIES CAN BE KEPT IN A CELLAR, WITHOUT VENTILATION?

AFTER reading Dr. C. C. Miller's article on "Ventilating Bee-cellars" I thought the very point I was looking for was passed over by both the doctor and yourself. He states, "Years ago I wintered 8 colonies in a cellar which was as tight as I could well make it," etc. "Those colonies came through in the finest possible condition—for the little air forced through the cracks of the cellar is enough for the few colonies. . . . But when I put 200 colonies or more in that same cellar, the case was materially changed." Very good; but where between the 8 and the 200 would the ventilation in that cellar commence to be needed? What should be the number of cubic feet to each colony, so managed in that cellar as to need no ventilation? It would seem to me, if these questions could be answered from observation taken, we should be on the right road to solving the problem of wintering bees. Even should one wish to put more than that or a certain number in a given cellar, we should know something of the amount of ventilation that would be needed.

A. E. SMITH.

Darlington, Wis., Aug. 22, 1887.

HOUSEHOLD CONVENIENCES—ANOTHER VIEW.

I have been greatly interested in the articles on home conveniences, written by Dr. Miller, Prof. Cook, and others, and can heartily indorse all of them; still, one point has not been mentioned, if I remember right. If we admit, for argument's sake, that our houses are inconvenient, our women overworked, and we are thoughtless, I still think there may be a little fault somewhere else. The writers I have mentioned have shown us that it is our duty to provide conveniences, and to remove inconveniences. How shall we know what conveniences to furnish—or, rather, whether a change made by us will be an improvement or not? Few of us are obliged to do our own housekeeping; but we are required to supply provisions, etc.; and as the latter duty takes nearly all our time we can not watch others to notice whether they are doing needless work or not; neither can we realize inconveniences they may labor under, as we could were we in their places. That is the way I look at the matter now, and I can suggest but one way to remove the difficulty. If the women who do our housekeeping will carefully think over their work, and see what causes them needless steps, and suggest an improvement, then I think we shall do our part, and their work will be made as easy as possible. If I were a wife or housekeeper I should do this, not in a fault-finding way, but pleasantly. Lots of men would make their wives' work easier if circumstances permitted.

G. A. HURD.

South Acton, Me., Aug. 29, 1887.

Friend H., by all means consult the women in regard to the improvements you are going to make; but a good many women, as well as other people, never think of there being a better way, many times, unless some one suggests it to them. A few days ago one of our women in the factory was filling glass jars with tomatoes, preparatory to

canning. She used a table-spoon, and was so long in getting the tomatoes in the jar I feared they would be so cold they would not keep. I asked her why she did not use the little tin tunnel we have on purpose. Now, although hanging within a few feet of where she was at work, she did not even know we had one. A little more observation showed me that she was trying to get the solid part of a tomato without the juice. I asked her why she did not use a perforated skimmer. She replied to this, also, that she did not know we had such an implement, and I was surprised to find there never had been one in the kitchen. Right at the head of the stairs—close by where they are at work—is our counter store, where four different patterns of perforated skimmers and wire dippers were hanging over the counters, and had been for years. In fact, we sell them by the hundreds. I carried them one of each, and told them to keep them and use them, and they were astonished to see what a handy thing a wire ladle is. Now, this we meet at every turn. People take slow and laborious methods of doing things, and wear themselves out with fatigue, when implements for doing the work better and cheaper are often, perhaps, right within a few yards of them. I have sometimes thought that we need more brains a great deal worse than we need more tools; and please, Friend H., don't rush to the conclusion that it is the women-folks alone who don't make use of, or who don't take short cuts with, the appliances that are already right at hand.

EJECTED HONEY.

It seems from the contents of the *American Bee Journal* of late, that the bee-keeping world is in a rage for a new name for extracted honey; and every name that could be thought of, almost, has been suggested; but none of them seem to suit Bro. Newinan. Well, so far as I am concerned the name "extracted" is as good as I want; but if anybody else wants another name, and nothing but a change will do them, then by all means let them call it by some word that simply expresses the truth in the case. Now, every Latin scholar knows that the word "extracted" means "drawn out"—from *ex*, out, and *traho*, I draw; and we all know that the honey is not drawn out, but thrown out. Well, if it is thrown out, then let us use the word that expresses that, and nothing more; to wit, *ejected*—from *e*, out, and *jacere* to throw or cast. Consequently we will call it *ejected* honey, if we must have a change; but I insist that a change is not absolutely necessary. However, if you want a change, Bro. Root, and the word I have suggested suits you, I hereby give you all the right and title that I may have (as the first one to suggest it) to the patent. So I shall in a few days order of you a "honey-ejector"—ha! ha!

Bees are working finely on my buckwheat. Weather is dry and cool.

J. G. NANCE.

Bellview, Ky., Aug. 31, 1887.

Friend N., the principal reason why I should prefer the name "extracted" alone, is, that I very much doubt whether the name *could* be changed, even if we tried ever so hard. When people get accustomed to a term, and use it a dozen times a day or more, the world over, it is a bigger task to

bring about the change than one who had not already tried it would imagine. Reforms in naming things in bee culture have been talked about for years, and some of them have been agreed upon, but that was the end of it. A very few tried for a little while to use the new name, and then got discouraged and gave it up. Shall we not let well enough alone?

GRAND DISPLAY OF BEES, QUEENS, HONEY, API-
RIAN SUPPLIES, ETC., AT THE OHIO STATE
FAIR, 1887.

Notwithstanding the dry season, one of the most attractive sights at the State fair could have been seen in the apiarian department of Agricultural Hall. Many of the stalwart bee-men of the State were there with bees, queens, honey, and supplies. The following persons were awarded premiums: Elias Cole, of Ashley, O., five premiums, aggregating \$30.00. Aaron Benedict, of Bennington, O., first on bees and second on feeder. C. E. Jones, of Delaware, O., was awarded 8 premiums. Dr. Besse, of Delaware, O., received four premiums. W. P. Crawford, of Delaware, O., three premiums. G. W. Newlove, of Columbus, O., first on thin foundation. Chas. McClave, of New London, O., received two premiums. The deepest regret prevailed, caused by the absence of the newly elected officers, the president and secretary of the Ohio State Bee-keepers' Association. Hoping that we may never have the opportunity to allude to their absence again, when their presence is expected, we will forgive the past and hope for better in the future.

Bloomington, Ohio.

S. R. MORRIS.

The president very much regrets his absence at the State fair—the more so, because the bee-men of our State did so well under adverse circumstances. If the real truth were told, he would have to confess that the date of the fair quite slipped his mind until after it was too late to get to Columbus in time. He and the secretary will try to make amends by doing all they can to make a rousing good convention, to be held in Columbus some time in mid-winter.

DO BEES EVER PUNCTURE FRUIT?

Does the honey-bee ever puncture the skin of any of our fruits, and afterward suck the juice? This subject has been under discussion at some length in the meetings of the Portage Co. Horticultural Society, and also of several papers read before the Garretttsville Antiquarian and Scientific Society. This will be again presented before the first-named society this month. I desire the opinion of the most noted bee-keepers on this important subject. I shall be pleased to learn your opinion at an early date; and when published I will forward you a printed copy of the paper on this subject.

GEORGE J. STREATOR.

Garrettsville, O., Sept. 1, 1887.

Friend S., this matter has been discussed over and over again for years, through our bee-journals; and the sum and substance of a great amount of the testimony seems to be about this: As a rule, bees do not and can not puncture fruit, even if they wanted to ever so much. A great many would stop right here, I presume. My opinion is, that they can puncture fruit to some extent when they get sufficiently excited, and when they are in sufficient numbers. As an illustra-

tion: I have seen bees so excited around overripe grapes that great clusters of bees covered the bunches, so that not a grape was visible. The bees were at such times rolling over each other, and fighting for the grapes. When bees get on such a raid as this, they will almost cut through inch boards, and at such times the grapes disappear—good, bad, and indifferent. Now, I can not say positively that there were any perfectly sound berries in any of the bunches; but my opinion is, after the best investigations I could make, that the bees had got a going so savagely they managed to cut into the grapes in some way or other—perhaps by starting an opening where the stems joined the fruit. May be they pushed so hard they crowded the fruit loose on the stems; and from what I know of bees I think the latter is quite probable. It is no more than fair, however, to add that we have good crops of Concord grapes year after year, right over our bee-hives. There are 400 or 500 bearing vines, and the bees have never yet worked on the grapes enough to destroy a single pound. Most seasons they never notice them at all.

HOW TO MAKE THE STOPPER, AS SHOWN ON P. 576.

When giving a description of my machine for emptying supers I omitted to explain the stops which hold the supers in proper position upon the bearing-board. They are shown in Fig. 6, at Z, page 576. They are formed by fastening to each of the end-pieces of the machine a piece of board three or four inches wide and $\frac{1}{2}$ inch thick (the width and thickness are immaterial), and long enough to extend backward as far as the back side of the super will require to go when being emptied. These are sawed off square at the back end, and another piece reaching across from one to the other is nailed on to them. This forms a stopper to keep the super from going too far back. A block is nailed into each corner of this stopper, of suitable dimensions, so that when the super is placed upon the bearing-board, and pushed backward against the stopper, it goes loosely between said blocks, by means of which it is held accurately in place while the follower is brought down upon it to remove it from the sections. The stopper for wide frames is made by first nailing a strip $\frac{1}{4}$ inch thick, and as wide as the thickness of the bottom piece of bearing-board, on to the back side. Over this is nailed a piece of board which extends upward above the upright bearings, high enough to form the stopper.

JOSHUA BULL.

Seymour, Wis., Aug. 17, 1887.

SUFFICIENT ENERGY AND ENTERPRISE, ETC.

On page 637, speaking of two Medina bee-keepers who got a big yield while their neighbors, north, south, east, and west, got nearly nothing, commenting upon it you observe, "Give us a man with sufficient energy and enterprise, and he will have a crop, no matter what the season may be." You certainly ought to know the way at Medina, but this time you are off to the "Lake of the Dismal Swamp."

J. HAMILTON.

Beason, Ill.

Well, I declare, friend H., I don't know but that I have got myself in a tight place this time. I don't believe I shall back out just yet, however, even if you and Dr. Miller

do crowd me pretty hard. A man with sufficient energy and enterprise would probably, in the course of time, start a honey-farm, and raise plants enough to furnish the honey. If a dry season came, so nobody else got any, he would put up a windmill and irrigate his grounds so as to get a big crop when the price was away up. There, don't you think I have made out a pretty good case, after all? I want to refer the above answer to Dr. C. C. Miller as well.

BEES REFUSING TO TAKE FEED.

We have been feeding our bees at the entrance (in Simplicity feeders) at dusk. It rains so often at night that we decided to feed in the upper story. We did so, and the bees at first took the feed (extracted honey) readily. We then thought we would give them more at one time, and so gave each colony 4 feeders full instead of one. The result is, that the feeders have been in the upper story of each hive about four days; and the bees, though they have free access to it, the same as when they had only one feeder, refuse to take any of the feed. It can not be that there is nectar in the flowers, for bees are gathering absolutely none.

E. & W. MONEY.

Cobham, Virginia, Aug. 27, 1887.

As you state it, friend M., I can not think of any reason why the bees should refuse to take the feed, unless it was something they disliked. It is, however, true that any colony of bees will in time get tired of being fed. I have made a single colony take a whole barrel of sugar; but toward the last they got so they would hardly taste it. Had the same kind of stores been secreted by the flowers in the open air, they would have labored with unabated energy until all was gathered, and more too. I have sometimes thought that bees reasoned something like this: "This food is already inside of our hive, and is our property. Why should we be in such haste to get it down into the combs? It can just as well stay here in the feeder until we need it." The above, bear in mind, is only conjecture; but I have oftentimes seen colonies act in that way, when in some of my experiments I have undertaken to feed them excessive quantities.

HOW TO MAKE A CLAMP TO WINTER FIVE COLONIES.

I want to make a clamp to put five colonies of bees in. Shall I need a drain to keep it dry? How deep should I make the pit? Will it need to have an inlet, and what size should it be, and what the size for the outlet? Will there need to be a hole in the top of each hive? SUBSCRIBER.

We sent the above to friend Hutchinson, and he replies as follows:—

I have made clamps upon a sandy knoll, and no drain was made or needed. Ordinarily I would have a drain. A 2-inch tile will answer for a drain. I would have the pit deep enough so that the tops of the hives would be but little, if any, above the surface level of the ground, and at the same time allow a space of about 18 inches below the hives. The sides of the pit may be made slanting, and terminate in an angle or point, at the bottom. For five colonies an excavation 4 feet wide and 7 or 8 feet

long, at the surface of the earth, is large enough. As mentioned above, the sides may slant to a "peak." No hole will be needed in the tops of the hives; but it would be well to have as much "openness" as possible at the bottoms of the hives.

W. Z. HUTCHINSON.

Rogersville, Mich., Sept. 1, 1887.

PUTTING THE BEE-SPACE BELOW IN THE T SUPER.

I have found it a decided improvement on T supers, which are to be used over zinc honey-boards, to turn up the metal supports $\frac{1}{4}$ inch, thus making a bee-space below. This prevents gluing sections to the honey-board, gives free access to supers, and brings the sections flush with the tops of supers, so that the enamel cloth lies down smoothly on the sections.

C. B. THWING.

Hamilton, Mo., Aug. 23, 1887.

Yes, you can so arrange the L tins in the T super as to leave a bee-space under the sections. This we at first suggested, as you will see by referring to page 156, current volume. But if you will turn to page 217 you will see good reasons for putting the bee-space on top of the sections. If you have only the plain sheets of zinc, I should still prefer to have the bee-space above. You then have to set the supers on two quarter-inch strips, to provide for the bee-space under the sections. I should never cover the sections with an enamel cloth, for the bees will propolize it to the edges of the sections. Better use a T-super cover, bee spaced above the sections.

OUR QUESTION-BOX.

With Replies from our best Authorities on Bees.

All queries sent in for this department should be briefly stated, and free from any possible ambiguity. The question or questions should be written upon a separate slip of paper, and marked, "For Our Question-Box."

Question No. 4—Is it wise to abandon the beveled edge on the Simplicity hive for the plain unbeveled or square joint when there are many thousands of beveled-edge hives in use? Are there any advantages to be gained in dispensing with the beveled edge? If so, what are they? S. J. M.

I have had no experience with the Simplicity hive. MRS. L. HARRISON.

I have never used the beveled edge, so I could not say. G. M. DOOLITTLE.

Being a manufacturer, I will avoid answering this question. PAUL L. VIALLO.

I do not really like the beveled edge, but would not change if I had many in use. O. O. POPPLETON.

I believe it would be in my locality. One advantage would be, more convenient to make; less trouble to adjust. In my locality every crook and turn is crowded full of propolis.

DR. A. B. MASON.

We do not like the beveled edge, because it is almost impossible to make the oil cloth, mat, or other covering, fit well on it. We would not use the beveled edge, even if every one else were using it.

DADANT & SON.

I much prefer the bevel omitted. If I had hives with the beveled edge, I do not think I should throw them away. Yes. They are much more simple, cheaper, less apt to split, and more readily closed without crushing bees.

A. J. COOK.

Perhaps not on the Simplicity hive. Uniformity is a great boon. The advantages of square joints over beveled edges are mainly to be found in the perfect lateral movement they allow when adjusting the edges together when bees are contained within the stories.

JAMES HEDDON.

On this I have nothing to say, as I do not use beveled-edge hives. We keep all our bees in quadruple hives, and they have square joints. I should think those thin beveled edges would get split off in handling.

E. FRANCE.

If my hives were all of the beveled-edge pattern, I would do some hard thinking before I made any change. If all the hives in the world were beveled, and I were commencing anew, I would have square joints, for the sake of simplicity and ease of manipulation.

C. C. MILLER.

The beveled edge is "a delusion and a snare." It was devised to keep the water out; but instead it seems to suck the water in worse than the square joint. Still, it may be better for Mr. Root's factory to go on making the bevel rather than to change. My favorite way of supering is with no upper story at all, consequently I am not bothered with either bevel joint or square joint, and yet all the surplus is taken by top storing.

E. E. HASTY.

I fail to see what bearing the number of beveled-edge hives in use has upon the question of their abandonment. The objections to the beveled edges are, that they are more difficult to make, and answer no useful purpose. They afford greater facilities for the bees to stick the two stories together with propolis, and when stuck together they are more difficult to separate—it being well nigh impossible to insert a knife or screwdriver, without mutilating the edges of the hive. When using hives two stories high these beveled edges are regular "bee-killers," as they go together upon the telescope principle, and there is no chance to avoid killing bees if the colony is so strong that the edges of the hives are covered with bees. With a plain edge the upper story may be put in position with a cornerwise movement that will brush away instead of killing the bees. No joint can fit any closer than a plain square joint; and if there is any crack, the bees soon stop it with propolis.

W. Z. HUTCHINSON.

I am not at all surprised, friends, at the answers given to the above query; for, as you will notice, very few have ever used it at all. Some of the other friends seem to be unacquainted with the way in which the Simplicity hive is designed to be used. In regard to propolis fastening the hives together, the Simplicity hive was never intended to be used so the bees could fasten the joints with propolis. The enamel cloth is to be fitted so closely that no bee ever gets above it with a load of propolis, therefore the cover always comes up as easily as the cover of a tool-chest. I am well aware, however, that very few take pains enough to keep the bees from filling these cracks

with propolis. In our apiary we use the Simplicity hive mainly for queen-rearing; and one great point in making the hive with beveled edges is to give us facility in handling them while empty—piling them into a wagon, for instance, tiering them up in a honey-house, or stacking them up outdoors, if you choose. They never slip or jostle, and do not tumble down or get blown off. Friend Hasty says they do not keep the water out any better than the square joints. My experience hardly agrees with him in this; and besides, if they don't keep the water out they certainly do keep the wind out better than a poorly made square joint; that is, unless said joint is filled with propolis, and we don't want any propolis at all to hold the cover on or to hold the upper story on. The only way we can change our method with the thousands of hives already in use, is to make them the usual way unless ordered otherwise than we have been prepared to do. Our books will show, however, that not one customer in a thousand wishes them made with square joints, especially if they have already commenced with the beveled joints. If we are going to use the stories in the shallow form recommended by friend Heddon, perhaps the square joint would be preferable, for the reasons that have been already discussed in our pages.

Question No. 5.—How much do you estimate it costs you per pound, in an average season, to produce comb honey? How much for extracted? If you can not say exactly, estimate as nearly as you can.

L. M. R.

Three cents for extracted honey. R. WILKIN.

About half a cent for extracted.

DR. A. B. MASON.

For comb honey, 8 and 10 cents. For extracted, 3 and 4 cents.

DADANT & SON.

For comb, 10 cents. I can not tell as to extracted, with my limited experience.

MRS. L. HARRISON.

As nearly as I could make it, I find that it cost me at least 3 cents per pound for comb honey, and 2 cents for extracted honey.

PAUL L. VIALLO.

According to the price of other commodities and of labor, both skilled and unskilled, I should say 10 cents for comb and 6 cents for extracted.

G. M. DOOLITTLE.

For comb honey, to put on the market, it costs me something like 5 cents per pound, independent of labor. If labor be added, the cost may reach 18 cents.

C. C. MILLER.

There is such a vast difference between seasons, different bee-keepers, and different locations, that I will not pretend to definitely answer this question in figures and amounts, nor do I attach much value to any number of attempted answers to it.

JAMES HEDDON.

The answer to this depends almost entirely on the estimate placed on one's own value, which deprives all such answers of much value to others. I could make a fair living in Iowa, raising extracted honey at 6 cents per lb., net, wholesale.

O. O. POPPLETON.

One of my intelligent bee-friends says that extracted honey costs 5 cents and comb 8, and that

all over that is profit. I feel that, from my own experience, I could hardly give an intelligent answer.

A. J. COOK.

We don't raise comb honey. As to the cost of producing extracted honey, see GLEANINGS for 1887, page 143, where I have given a detailed account of the cost for the year 1886; viz., 3½ cents per pound. But average last year with this, then this is about double last year's figures.

E. FRANCE.

I have always raised extracted honey in connection with queen rearing, or with comb-honey productions; it has come from odds and ends, hence I can not estimate the cost. I know exactly what it has cost me to raise comb honey, but I had a little rather not tell. It is a little too rosy-hued, and might cause an undue influx into the bee-keeping ranks. It has cost me less and less each year, too, as I have adopted improved methods and fixtures.

W. Z. HUTCHINSON.

Lumping it off at random, I say that in labor and cash supplies my comb honey costs me 10 cents per pound. By charging fancy prices for labor, valuing buildings, hives, bees, etc., at high prices, and computing interest at high rates, it would be easy to say that the honey costs me 20 cents per pound; but I'm not going to say that. We all know about the prosperous merchant who spends his life selling goods for less than cost, and dies worth a million; but it's just as comfortable to say we are making a living when we are. The point is, What would we be making at "that other business" if we gave bee-keeping up? And if we could sell our services for somewhat more, is not the comfort of being one's own master enough to turn the balance? Extracted honey, I produce too little of to figure on.

E. E. HASTY.

Question No. 6.—Is extracted honey that is artificially ripened, equal to that ripened by the bees?
G. A. R.

Not to my taste. W. Z. HUTCHINSON.

Almost, but not entirely. R. WILKIN.

Yes, entirely so, if properly done. A. J. COOK.

Most certainly so, if properly done. O. O. POPPLETON.

In my judgment it is not—nowhere near it.
JAMES HEDDON.

No. I have always found a perceptible difference in the taste. PAUL L. VIALLO.

Yes, when intelligently handled under right conditions as to air and temperature.

MRS. L. HARRISON.

It depends on the season. In a wet season, yes, and better; in a dry season, the bees are ahead.

G. M. DOOLITTLE.

Yes. We never ripened honey artificially; but if properly ripened, we do not see why it should not be as good. DADANT & SON.

I think not quite. Is the calf raised by hand equal to the one that sucks the cow? He may be made so, perhaps, but mostly he isn't. E. E. HASTY.

We have never used any artificial means to ripen honey. We don't extract until the honey is thick enough to keep well, therefore I can not say.

E. FRANCE.

No. Some of it, perhaps, is, and it is possible that one who knows his business may equal the bees.

C. C. MILLER.

I believe it is, very nearly; so near that I don't wait for the bees to ripen it. A specimen of it, shown at the last Michigan bee-convention, was pronounced "good enough for anybody" by Prof. Cook, T. F. Bingham, Mr. McPherson, of the *Canadian Bee Journal*, and others. DR. A. B. MASON.

Every boy or girl, under 15 years of age, who writes a letter for this department, CONTAINING SOME VALUABLE FACT, NOT GENERALLY KNOWN, ON BEES OR OTHER MATTERS, will receive one of David Cook's excellent five-cent Sunday-school books. Many of these books contain the same matter that you find in Sunday-school books costing from \$1.00 to \$1.50. If you have had one or more books, give us the names that we may not send the same twice. We have now in stock six different books, as follows; viz.: *Sheer Off, Silver Keys, The Giant-Killer*; or, *The Roby Family, Rescued from Egypt, Pilgrim's Progress, and Ten Nights in a Bar-Room*. We have also *Our Homes, Part I.*, and *Our Homes, Part II.* Besides the above books, you may have a photograph of our old house apiary, and a photograph of our own apiary, both taken a great many years ago. In the former is a picture of Novice, Blue Eyes, and Caddy, and a glimpse of Ernest. We have also some pretty little colored pictures of birds, fruits, flowers, etc., suitable for framing. You can have your choice of any one of the above pictures or books for every letter that gives us some valuable piece of information.

CONDUCTED BY ERNEST R. ROOT.

THE BOYS' BEE-HIVE FACTORY.

WIND AS A MOTIVE POWER; MORE LESSONS IN HANDLING BUZZ-SAWS.

THE next day the wind continued to blow, and the air grew decidedly cooler. In fact, it really felt cold, after the warm weather. The windmill was revolving at a fair rate of speed. The boys decided that, as other factories and shops started up at 7 o'clock, they would do likewise. Accordingly, promptly after breakfast they were on hand. It was agreed that Sam should saw. The night before, the two had taken up into the loft as many boards as they thought they would need for the day. These long boards (12 feet long) were piled up so as to be convenient to the saw-table. Jimmy held one end while Sam gauged the proper length of the boards, and held them square against the figure four, while the saw was cutting through. At first Jimmy and Sam quarreled somewhat. Jimmy complained that Sam was careless, and that he didn't hold the boards up square against the gauge. Sam, in turn, accused his companion of not doing his part correctly.

"How do you suppose I am going to hold the boards square against the figure-four gauge if you keep whopping your end of the board one way and then the other?" said Sam?

To make matters worse, they would get just about in the middle of a board, and

then the windmill would seem to stop and take a breath. At other times it would scold, and seemed to whine because its little masters gave it too much work to do. Finally they succeeded in cutting off a dozen lengths of boards, or such a matter, and then the windmill began to run, so slow that it was impracticable to cut boards. The boys, impatient to continue their work without interruption, were obliged to wait until another gust of wind came along.

"I tell you," said Jimmy, "it is a confounded nuisance to work this way."

"I know it is," said Sam, "but it is a good deal better than cutting off boards by hand. I wonder why the wind does not blow all the time. Off in the field there the wind seems to be waving the trees. There must be something wrong with our windmill. There is pa down there. Let's ask him what he thinks about it." While they were talking thus, Mr. Green came into the barn to see how they were progressing.

"Well, boys, you have made a start, have you not? Why aren't you at work now?" said he, as a twinkle gleamed in his eye.

"Say, pa, what is the reason those trees are waving their tops, and yet our windmill won't run?"

"I have just been thinking of this very same thing myself," said Mr. Green, "and I think I have an explanation for it. The wind is, as you notice, in a southwesterly direction; directly in range is a maple-tree standing in front of the mill. When the wind changes a little, I think you will not experience quite the same trouble."

"But, pa, yesterday, when the wind was directly in the west, the windmill had this fashion of humming a while, and slacking up and stopping just when we wanted to work."

"Suppose, boys, we get on top of the barn where we can observe matters a little more closely."

This proposition was no sooner put forth than it was put into execution. From the roof, Mr. Green mounted the short windmill-tower, in order that he might better detect the breeze.

"See," said he; "clear over yonder, some 300 or 400 yards, the trees are waving quite hard, and yet the wind is not blowing here at all, scarcely."

"That's so," chimed the boys. Very soon, however, the leaves rustled on the trees, and the windmill immediately commenced revolving at a pretty good rate of speed.

"Oh! I think I see," said Mr. Green. "There seem to be gusts of wind traveling along; and when you saw the trees at a distance from the barn window, waving, you saw one of these gusts coming up. Didn't the wind mill, soon after, commence revolving?"

"Yes," said Sam; "I now remember it did on several occasions."

The three then descended to the ground. Sometimes, when the windmill was going at a pretty good rate, they felt no breeze whatever. Again, the breeze seemed pretty strong, and yet the windmill moved not.

"There seems to be an upward and a lower current traveling," observed Mr. Green.

While they were thus talking, the wind-

mill started briskly; and the boys, eager to make use of the opportunity, ascended to the barn-loft, accompanied by Mr. Green. They cut a few lengths of boards, and then the windmill stopped as before.

"That is enough to make a fellow mad," said Jimmy.

"You must not expect," interposed their instructor, "that wind power is equal in steadiness to steam power or water power. We have already observed that there are gusts of wind that seem to travel about; and when one of these strikes the mill we have an abundance of power. In the intervals the mill may run very slowly and perhaps stop. Now, while we are waiting for more wind, suppose we remove the crosscut and put in its place the rip saw. Crosscutting is a little different from ripping; and while I have the opportunity I want to instruct you in ripping up frame-stuff, edging boards, etc."

"What do you mean by edging boards?" said Jimmy.

"I mean, making the sides of the boards at right angles to the ends which you have already cut off."

"Oh!" said Jimmy; "I see."

Jimmy proceeded to lift up the saw-table. He took up a wrench. He twisted and twisted, but the nut which held the saw in place on the mandrel would not stir.

"Wait a moment! you are turning the wrong way."

"Why, I am turning it just the way *all* screws are made, when you want to unscrew a screw."

"But you must remember," said Mr. Green, "that I told you that when you wanted to take off the saw from the arbor you must turn the nut in the opposite direction from which you are accustomed. In other words, you are dealing with what is called a left-handed screw. Turn the other way."

Jimmy did so and it slipped off easily. Instead of taking a wrench, as is customary, Mr. Green told Jimmy to take a hammer and strike on that side of the nut that will take the nut off.

"Yow see, if the screw on the mandrel were a right-handed screw, the saw would untwist the nut; therefore we are obliged to have a left-handed screw, the same as you will find on the left side of a buggy."

Accordingly, when Mr. Green slipped on the rip-saw he turned the screw "backward," as Jimmy said.

By this time the wind had started up again. In the meantime Mr. G. had removed the figure-four and adjusted the parallel gauge so that there was about a quarter of an inch distance between it and the humming saw. He next took up a board about a foot long, and shoved it through.

"Yes, that works very nicely," said he. He then raised the saw-table so that the saw just projected through this seven-eighths board, after which he sawed the board into narrow strips; but while cutting the strips he used the push-stick, such as has been previously described. Just at that moment a friend of Mr. Green came to see him, and he was called away. After he had gone, Jim-

my picked up a board and proceeded to cut it into strips, as did Mr. Green.

"That is just fun," shouted he, when he had ripped one or two strips. As he got about half way through the third strip, the wind gave visible signs of giving out; and before he could cut through it, the windmill stopped altogether. Jimmy withdrew the board, and impatiently waited for the wind to return. This time, however, he was not obliged to wait long. He had hardly got the board out before the buzz-saw began to hum in a low key, and then finally it reached its usual speed. As the board was not cut quite through, he changed ends so that the saw might meet its former cut. Sam noticed that Jimmy's finger was quite near the saw-teeth; and that when the saw reached the former cut the board was liable to slip by, endangering his companion's finger; but before he could speak, his fears were realized, and the other screamed out, "I am cut! I am killed! oh, oh dear!" as he saw the blood spirt from the end of his finger. It proved to be, however, only a flesh wound, for the skin had been cut through only enough to make his finger bleed profusely.

"I was just going to tell you," said Sam, "that you were liable to cut yourself there."

"Well, why didn't you, then?" moaned Jimmy angrily. "You are a pretty fellow, you are, to let a fellow get cut in this way."

"The fact is," said Sam, endeavoring to justify himself, "I tried to tell you just as soon as I could; but it seemed to me I could not get it out in time."

Mrs. Green, hearing Jimmy's first scream, came over to ascertain what was the matter. She looked at the wound, and pronounced it nothing serious. She quickly wrapped it up in rags, and told the boys they had better not do any more that day, as neither one of them seemed to be in a very good mood.

"You ought to be thankful," she continued, "that you were hurt no worse. You might have lost your finger, or two or three of them. I don't know, but I can not think it is wise for you boys to try to do any thing with buzz-saws."

"O yes, ma, it is," said Sam; "we won't get cut."

That evening Mr. Green inquired how it was that Jimmy was cut. In the first place, he discovered that Jimmy had omitted to use the push-stick. This, he had forgotten. Jimmy, however, was inclined to lay the blame on Sam, because he didn't speak quicker.

"I have been in just that predicament myself," said Mr. Green. "I find that it takes time for mind to produce a sensible effect upon the nerves. Sam probably saw what was about to happen; but he found that, before he could cause his vocal organs to give the alarm, the mischief was done. It is not definitely known how long it takes the mind, in conjunction with the human frame, to result in action. But repeated experiment has shown that it takes an appreciable time. Sam, under the circumstances, therefore, did the best he could. A buzz-saw, you know by this time, Jimmy, will not wait for boys to get out of the way."

JUVENILE LETTER-BOX.

1300-LBS. OF COMB HONEY FROM 60 COLONIES.

This is my first letter to you. My papa is a Christian preacher, and keeps bees. He has 60 colonies. We keep supplies of all kinds. We took about 1300 lbs. of comb honey. It has been very dry since the first of July.

OREN HUMMEL.

La Fontaine, Ind., Aug. 18, 1887.

HONEY FROM SUMAC.

My brother has eight bee-hives. The bees are getting honey from sumac. It is very dry here now. My brother uses the Simplicity hives. When more than two stories are used he puts the new hive next to the bottom. I am anxious to know how Jim and Sam are getting along with their bee-hive factory.

WM. MORGAN.

Belton, Tex., Aug. 14, 1887.

HONEY FROM IVY, ETC.

My pa has seven swarms of bees. My uncle wintered them for us, as we moved to town last winter, and we could not take them very well. Bees are not doing much now. They have been making a little honey from sourwood and ivy. I do not like ivy honey. It makes me sick. I am much interested in Sam and Jim's bee-hive factory; also how they got along with their buzz-saw. I like to read the juvenile letters, also the many other interesting and useful letters.

ERNEST B. HUGHES.

Pipestem, W. Va., July 29, 1887.

MAGGIE'S POETRY.

Papa has 45 stands of bees. He has more bees than any one else in the neighborhood. Our next-door neighbor, Mrs. Lowden, had one stand of bees at first, but papa kept increasing until she has four stands of bees now in good order. We have taken off quite a lot of honey. Everybody in this valley is afraid of bees except papa, so he has to take care of them all. Mamma always helps papa take care of his bees. Here are some verses I wrote:

Hear the little bees,
Working all the day,
Sipping honey from the flowers
That grow along the way.
We should love the little bees,
And treat them very kind,
For they have children great to hear,
For such a little mind.
We go into their little homes
And rob them of their honey,
And take it to the city
And trade it off for money.

MAGGIE JONES, age 10.

Walla Walla, Wash. Ter.

SWARMING, AS REPORTED BY CLARA.

Our apiary is situated between two hills and near a swamp, and within half a mile of the Harford fair-grounds. Papa's 16 swarms of bees have increased to 32. One of the first swarms that came off came out and alighted down in the swamp. Papa went and brought them up and hived them, but they went back into the old hive. The next day he was going past there, and he heard some bees. He looked up in the tree and saw about two quarts of bees that he had left the day before. He brought them up and put them into an empty hive and put a frame of brood into it. When he brought it up he supposed that the queen must be with them; but a large swarm came from that same colony the next day. He then put them in with the two quarts of bees.

Papa has had but one second swarm this year

that he had to hive, and that came out one Saturday for the first time, and they went back; but they came out Sunday again, and he put them back into the old hive. They stayed that day, but they came out again Monday, and he put them into a new hive, but they would not stay. They went back into the old hive again. Tuesday they came out again. He put them into the new hive, and put a frame of brood into the hive, and they stayed. They did not alight in the same place any of the four times; and the last time they swarmed they alighted on the corner of a fence. We had one swarm that came out just as a hard shower was coming up. It had commenced raining before they had all got out, and it was raining quite hard before papa had them hived. It was the hardest shower of the season. We had another colony that did not swarm until two or three days after papa knew that the queen-cell was sealed.

Papa has taken off 510 lbs. of white honey, and has extracted nearly 80 lbs. One day he had a couple of queens that hatched from the newly cut-out queen-cells. He had a couple of colonies that had just swarmed, and he thought he would let them run in at the entrance. He made a mistake, and let them both run in at the same entrance. A day or so afterward he was looking for them, and found one of them in front of the hive.

Harford, Pa.

CLARA B. LINDSEY, age 11.

THE SEASON OF 1887.

SOMETHING FROM OUR YOUNG FRIEND CHARLIE L. GREENFIELD.

MR. ROOT:—As the honey season has long been past, I will now send in my report for 1887. This season was the poorest one for bees ever known here. Bees came out of winter quarters in fine condition. The maples came in bloom March 6th and the bees began work on them quite lively, gathering honey as well as pollen. The first part of the season up to June was cold, cloudy, and breezy, with only occasional warm spells, and the nights were quite cool. Consequently all this time bees made but a living. Then white clover opened up and I never saw as heavy a crop of bloom. But for all that, it contained but very little honey. The bees worked on it some, slowly collecting honey, and in course of time most of the hives were fairly supplied. Basswood opened up in a dry time, and did not last long. Not more than one-third of the trees produced bloom. All of the bees raised drones early in the spring; but buckeye bloom stopped suddenly, and all the drones were killed. Immediately after they were killed, locust began blooming, and a second lot was raised. We did not have a swarm this season, and we did not get much surplus. After basswood closed, a few scattered wild flowers kept the bees in honey for brood-rearing for a while, but they soon quieted down. Then came the long scorching drought of several weeks, during which time the bees did nothing. At present, all of the bees are gathering immense quantities of pollen, and a little honey. All of our colonies are very strong, and are raising brood heavily. Although nearly September, two colonies have drones flying strong. These drones were hatched out lately, and were reared during the drought. The bees show no tendency to kill them. The hives are populous, and

have good queens. I never saw bees less inclined to rob than this year. I rarely ever see a robber prying about. I have done lots of feeding lately in the day time, and have examined hives in the middle of the day, but never had a robber to bother.

BEES STEALING EGGS.

In the spring we had one weak colony that remained so throughout the season. It had a queen, and raised brood right along; but owing to the poor season it did not increase much. It no more than made a living all summer. In June I looked into it and saw some sealed brood. I did not look at it again until the last of July. Then I examined it. There was no queen in it, nor any brood or eggs. There were two queen-cells containing larvæ. With the exception of these two larvæ there was not an egg nor any brood in the hive. In due time the queens were hatched. Now, the question is, Where did the eggs come from? I do not know of any way that they could have obtained them, only by stealing them from some other hive.

BEES DYING AROUND HIVES IN JUNE.

Along in June, several swarms suddenly began to die. The bees would crawl out and die on the ground in front of the hives. I examined them, and found them all to be as I supposed, young bees, because all had a clean bright appearance, and all had perfect wings. They were all of their natural color and size, and not one thing could I see wrong with them. In the morning they would be scattered around the entrance. Of nineteen colonies, about half were affected. I have seen the black, shiny, nameless-diseased bees, but not one of these was black. They were not dragged out, but they crawled out of their own accord. It was not starvation, for they had plenty of honey at the time. They died for about a week, and ceased as suddenly as they commenced, and I have never seen a trace of it since. What do you suppose was the matter?

Somerville, O., Aug. 28, 1887. C. L. GREENFIELD.

Friend G., in regard to bees stealing eggs, I would suggest that the queen failed gradually; that is, she laid fewer and fewer eggs, until finally she laid only one or two a day. These last one or two, the bees used for those queen-cells; therefore you discovered there were no other eggs in the hive. In regard to the young bees that came out and died, I have seen something of the kind, but I don't know that I can offer any explanation, unless it is that the dearth of honey might have caused them to neglect giving the larvæ the proper amount of nutriment, therefore they were so enfeebled they died before they were able to fly. This might have happened because the bees were out of stores, say not more than 24 or 48 hours, just at a time when these young bees in the larval state needed food. I once cut a bee-tree in the woods, where not a drop of honey of any kind could be found in any of the combs. The bees had been living from day to day on the honey they obtained from the feeder in our hunting-box; and as we were a week or ten days in finding them, they had probably been destitute of stores for that length of time. Of course, they had not a particle of brood. Now, had they tried to rear brood under such circumstances, I can readily imagine the young bees might be so feeble they would never be able to fly.

OUR HOMES.

The blood of Jesus Christ cleanseth us from all sin.—1. JOHN 1 : 7.

Ye must be born again.—JOHN 3 : 7.

THE question is continually arising, "What does Christianity do for a man?" A good many whose attention is called to the matter reply, "How much does it amount to, any way? How much different is the man who is a Christian, from anybody else? Is it really of any very great consequence?" The friends who love righteousness, no doubt feel hurt and chilled by such expressions as these; but they are continually coming from the world, and those who treat lightly the subject of Christ's claims upon us are all continually demanding that we prove to them that there is a reality in the religion of Christ Jesus. They often say, "How can you prove to us that it amounts to any thing more than these various other things that come up? Various societies urge the importance of their special organization, and what has Christianity to offer more than a thousand and one other things?" In other words, the world insists, or, at least, a great part of the world, that Christianity is on a level with ever so many other things, and that there is no particular need that it be the all-absorbing topic.

Skeptics and infidels, however, often understand and acknowledge our claims, but they declare the facts don't prove it. At a temperance meeting some time ago, the matter of gospel temperance was under discussion. Some of the unbelievers of our town, who are friends of temperance, demanded a non-partisan temperance meeting. They wanted to attend and take part, but they objected to gospel hymns and prayers. A smart lawyer, who seemed their leader, expressed himself something in this way:

"Some of us who have not had our 'sins washed away' are interested in the temperance reform, and wish to help the matter along."

When he spoke about sins being washed away, he made a somewhat comic expression with his face, and glanced around at the professors of religion, expecting them to smile at his witticisms. Some of them, perhaps, did smile; but my good old mother, who was present, didn't smile. In fact, she had never heard such talk, and was so much pained that she declared she could not stay where such language was used. In thinking the matter over, however, it has occurred to me that there was a good rebuke in the lawyer's words, for many of us. I wish to say, however, that few Christians of my acquaintance have claimed that their sins are all washed away, in the sense in which the lawyer used it. We do claim, and we have a right to claim, that a free pardon has been granted us, for sins committed before we enlisted in Christ's service; but we do not claim that our lives are sinless or spotless. We are but dust after all—even as the Psalmist says, "He knoweth our frame, that we are but dust." But even though this be true, I do think, dear friends, that

we are all of us a good deal more "dusty," as a former pastor of mine used to express it, than we need to be. The blood of Christ does cleanse from all sin, as our text declares, providing our trust, our whole trust, is in Him who died that we might be cleansed. I do not know whether or not Christians will be graded or classified in the great unknown future; but I am compelled to admit, that there are many grades of Christians here in this world. And while I admit this, I am also compelled to acknowledge that there are but very few, comparatively, who reach the high Christian attainment that is open to us all. There are thousands of church-members who seem to be, judging from such glimpses as we get of them in their every-day life, but little more than church-members. Now, lest you think I am going to find fault with others, I will come nearer home, and say that I am afraid that a good many see nothing in me nor in my own life, particularly indicating that I am any thing more than simply a church-member. In saying this, I do believe it is a grand thing to be a church-member, if nothing more; that is, it is a great thing to let your life show to the world an absence of any thing wrong, or any thing that would be derogatory to a professor of religion, even if it does not show much on the other side; that is, a negative sort of religion is better than none at all. But, my friends, a real, live, bright, active religion is better still—a religion that carries praise with it as well as prayer, and this, overflowing day by day and hour by hour with the joys of the Christian's hope.

When we enter Christ's service, we ought to be different from what we were before, and in one sense we ought to be different from other people. A change should be recognized in us at once, and it should be so great that our friends recognize us as different persons. Christ said to Nicodemus, you may remember, "Ye must be born again," indicating that the change from the worldly man to the follower of Christ should be so great that it would be in reality a true and new birth. I am sure it is our privilege to show to the world a greater change if we would. We ought to be growing in trust and growing in grace. We ought to be making practical applications of the words of the Master whom we follow, every day and every hour.

A few days ago a young man whose life has been remarkably free from fault, and who, in fact, seems to be free from *any* of the temptations that beset the rest of us, for almost the first time in his life got entangled in a worldly matter. I should say, he got into a *quarrel*, but I am afraid, now, he would hardly be willing to admit it. I hope, friends, you will excuse me for saying that, in one sense. I felt a little glad to know that he had got into a quarrel, for I wanted to see him use his weapons, and test them fully. Here in our factory we have got some fire-extinguishers. Before I purchased them I saw them tested on a bonfire in our public square. They worked splendidly on a make-believe fire. Well, since then I have been somewhat anxious to see a real fire—

just a little one, that I might test my skill and test the extinguishers. I want to try our weapons. Now, mind you, I don't want anybody's house to get afire; but if it does get afire, I am going to try hard to be on hand promptly with our new weapons. In the same way I was glad to be on hand when my young friend had become really entangled in a live neighborhood quarrel. With a little encouragement he would talk by the hour about the evil disposition of his opponent. He said nobody could get along with him—not even the person's own relations; and although he is naturally remarkably cool and level-headed, I could not but smile to see him get really excited about a matter that was trifling and unimportant. By a little questioning, I perceived (at least I thought I did) that his state of mind was the result of having dwelt on the subject a good deal. Judging from my own experience, I should say he had wasted enough valuable mental strength and time on this foolish matter to have written a tolerably good-sized book. In fact, had the whole subject been arranged and classified, he might have dictated to a shorthand writer a volume; and his whole heart and soul were so taken up with it, I think he would have done it eloquently. And this reminds me that I once heard a great city editor, who had got into a similar quarrel with his own brother, speak about publishing a book to show to the world his own brother's sins and weaknesses. I do not know but that he calls them crimes. Now, just think a moment of a man sitting down to write a book to tell the world how bad his own flesh-and-blood brother is! Does not this single point illustrate to what lengths Satan may carry a person, if he does not watch and pray against it? Well, after I had talked with my young friend, and drawn him out quite a little in regard to the matter, I suggested to him that he try Christianity. He replied at once that it was of no use, and to the effect that it would be like casting "pearls before swine." How exceedingly natural it is to take this ground! Did you ever stand there, my friend? I cautioned him, and replied that it was certainly his duty to test Christ's teachings, and then I commenced repeating some of these wonderful texts that strike right squarely and directly on such troubles. Perhaps my texts were not the best ones I could have chosen, if I had had a little more time, or with the Testament right before me. But I was astonished and surprised to see with what wonderful force they struck. When the contents of the fire-extinguisher were turned on to the bonfire, exclamations of surprise came from the crowd, to see that great roaring, scorching fire subside and vanish in an instant. Christ's words seemed to have much the same effect on this young friend's state of mind. I was pleased, and said inwardly, "Thank God to see him stand the fire of these texts so well." Even though Satan had, for the time being, led him a little out of the straight and narrow path, the true metal was there still; and instead of evading or avoiding the issue, he bowed at once before the sublime words,

even as did poor Thomas, when his doubts were removed—"My Lord and my God." I think the first text I quoted was:

"But I say unto you, love your enemies."

He looked at me in silence, but I could see that he felt the application. Then I repeated:

"Do good to them that hate you."

This time he took a little courage, and made something of a defense.

"Why, I have tried, over and over, to do him kindnesses;" and then he went on relating the different times in which he had done *more* than his part, and had been more than generous. Satan was getting a little hold on him again; and, my friend, whenever he gets up to recounting a list of our good deeds and generosityes, it is Satan, you may be sure. But when I added, "Pray for them which despitefully use you," he had nothing to say. Quietly I asked:

"Have you really been praying for this individual?" With downcast eyes and humble voice he replied:

"To tell the truth, I have not."

Perhaps you may think, dear reader, that this was bearing on rather hard, especially with a young Christian. But this young friend knows me so well that I am sure he didn't think I meant to set myself up as one free from like sins. In fact, I think he knows full well that my life has been a constant succession of such conflicts. If you think, dear friends, that it is easy and natural for me to pray for one who has wronged me, you are greatly mistaken. We admire this 44th verse of the fifth chapter of Matthew, when applied in a general way, or when held off at arm's length; but if you have not tried it, my friend, just wait until you get greatly stirred up because somebody has deliberately and purposely abused and wronged you; and then while you are stirred up, go off and try to pray for them. I have tried it, and I know what it is to have Satan say to me, "Why, you silly fool, you can not pray for that man, if you try. It is not prayer at all—it is only a sort of despicable hypocrisy. Far better stand up like a man, and assert your rights."

Did Satan ever address you thus, my friend? If so, don't let him swerve you from the path of duty a particle. Just say, "Get thee behind me, Satan," and then put your whole trust in the Lord, and be not afraid.

Some one may ask, "Is there not such a thing as carrying this too far, and letting people run over you?" To which I reply, I am sure there is not, if you use good ordinary common sense. Bear in mind, we are considering difficulties with our neighbors—with such people as are to be found by the score in your neighborhood and in my neighborhood; or, if you choose, with just such people as you and I are. Some of our greatest and best minds have been so diverted by trifling personal quarrels as to spend time enough upon them to have given us books that would have been a blessing to humanity and the world; and I have sometimes wondered if there was ever a great man or great woman who lived so close to the Savior day by day and hour by hour as never to have

wasted any precious moments in this sort of folly. If you are dealing with a highway robber, or a man bent on committing crime, it is quite another thing. It is right for you to pray for the burglar who gets into your house at night, and it may be right for you to take his life while you pray. I do not think that any of Christ's words mean that we should practice non-resistance where we are dealing with men who have deliberately decided to commit crime.

Now, before closing this paper I want to give you another illustration of the way in which the blood of Christ cleanseth from *all* sin. I want to tell you a little story that I tried to tell you once before. The reason why I tell it again is because it applies so completely to this question often asked—Can a thoroughly bad man—a hardened criminal, for instance—be reached so as to make him over into a thoroughly good man and a Christian? Some ten or twelve years ago a man in the neighboring town of Akron robbed the American Express Co. of a very large sum of money. If I remember correctly, the sum was about \$16,000. I know but little of this young man's early history, but I take it for granted that he had been for years in Satan's training, and had become intemperate, reckless, and dissolute, and all these things. No one commits a crime like this unless he has had years of practice, and gone down by gradual steps. He was smart and shrewd—in fact, so much so that nothing could ever be proved against him. After a long and expensive trial he was acquitted, and the express company gave it up in despair. After the trial was over he was free to go where he pleased, and to indulge to his heart's content in all that this world can furnish; that is, so far as things go that can be purchased with money. I do not know that he ever found satisfaction and happiness in paying out his ill-gotten gains or not. It was about the time of Moody's successful work in Chicago; and although hardened criminals seldom go to religious meetings, for some reason or other this young man followed the crowd to hear Moody. Perhaps out of curiosity, he thought he would see what this man who was making such a great excitement had to offer. Perhaps, to his great astonishment, he heard of something that God has in store for his children, that money will not buy. Under the influence of God's divine Spirit, Moody's eloquence touched the heart of even such a hardened sinner as this one. I can imagine that he, may be for the first time in his life, got just a glimpse of a human life devoted to Christ and his service, instead of to self and the gratification of selfish desires. He remained after meeting, among the inquirers, and finally confessed to Mr. Moody his crime, and asked him what he should do to be saved. Mr. Moody, as a matter of course, told him to carry back the stolen money—at least, what there was left of it.

"But," said our friend, "I should be at once arrested and sent to prison."

"And that is exactly where you want to go," replied Moody.

"No, I don't," replied the stranger.

"Then you must go back to Satan and his service; for the only road to salvation for you is to make restitution, and submit to the law."

I can imagine that a long talk followed. Our friend was slowly groping out of the darkness into light. He was counting the cost. I tell you, my friends, it would be a good thing for us if we would count the cost a little more than we do sometimes. Christ said, "Which of you, intending to build a tower, sitteth not down first and counteth the cost, whether he have sufficient to finish it?" The end was, that he promised to go home and give himself up. Moody electrified the audience one evening by telling them the simple story, so far as I have told it, and remarking at its close that the young man who committed the crime was then present in the audience. When the time came for him to start home, he went to Moody, a good deal disturbed, and declared that he could not go back home and give up the money, unless Moody himself would go along with him. Moody replied:

"I can not go with you, my friend, and I don't need to go. The Lord Jesus, whom you are now trusting, will be with you and strengthen you. While he is with you, Satan can not get you off from the track. You will not turn coward, and desert, for I will pray for you. Follow straight in the path of duty—give yourself up, pay the penalty according to the requirements of the law, and peace in this world, and eternal life in the world to come, are before you."

Under the inspiration of these kind words our friend went forward; and every step he took toward the right, encouraged and strengthened him to take the next step. The old self was dropping away. His selfish passions and selfish purposes were dying a natural death. The old life was dead, and he was entering upon the new birth, even as the words of our text say. The words to Nicodemus, when he came on that visit by night, were true—"Ye must be born again, if ye will enter the kingdom of heaven." Is there any more beautiful or encouraging sight in this wide universe than that of the new-born Christian?

Our friend went back to the express office where he had been employed, and handed over the money. Those who had fought him in the lawsuit were aghast with astonishment. Like the disciples of old, they doubtless said within themselves, "What manner of man is this, that not only the winds and the seas obey him, but by his words the thief who has evaded justice comes back and restores the stolen property?" After he convinced them that he took the money—that is, if any evidence were needed—they were still more astonished to hear him demand that he be sent to the penitentiary, and punished as the law directs. Such a thing was unheard of; and when the officers of the law, after investigation, declared that one who had been tried and acquitted could not be punished, our friend looked disappointed and troubled. No doubt the world called him crazy; but, my friend, the best common sense that ever shone forth from human eye was in his

heart then, when he wanted to go to prison. If I remember correctly, he wrote back to his friend Moody. How natural it is for us to cling to those who have been instrumental in leading us from death to life! Moody told him to ask them to send him to the penitentiary for perjury. A new trial was instituted, and this time the *criminal* helped to bring witnesses to prove himself guilty. Crazy again, say you? Not so, my friend. The sunshine of God's free love was round about him. What cared he for earthly applause or for earthly pleasure? What cared he for prison walls and iron bars? The light of heaven, and the peace that Christ can give, were his; and with happiness in his heart, and a joy pervading his whole being, that fall to perhaps but few mortals, this penitent thief went his way to prison. He was a new man, with new tastes, new aspirations, and new joys. Who could for a moment recognize him as the hardened, guilty criminal of but a few months before? Do you still feel like saying, that men and women may be hardened by sin and crime so far they can not be made over and cleansed by the blood of Christ? If so, I would refer you to hundreds in the city of Akron, who can tell you the circumstances of all this little story more faithfully than I have told them. As a matter of course, he was kindly treated in the penitentiary. Instead of being received as a convict, he was received as a man and a gentleman—nay, even as one of God's noblest works. An easy berth was given him, and no doubt he felt like complaining that they did not punish him according to the full letter of the law. What a sad contrast this is to the story some tell who come from there, of the indignities and the hardships they endured. I always feel troubled when I hear a returned convict complain of the treatment he received, instead of saying he was treated ten times better than he deserved. A few days ago I told this story at our noon service; and at the time I did so a gentleman was present who lives in Akron, and knew the young man well. He said I got it right in every particular, so far as he could remember. The offender is dead now, but he died with that new-born hope in his breast—died, doubtless, rejoicing as he lived the remainder of his days—rejoicing in that full and free pardon, and in the fact that the blood of Christ is indeed able to cleanse even the most hardened and corrupt from *all* sin.

TOBACCO COLUMN.

A KINDLY CRITICISM IN REGARD TO OUR TOBACCO COLUMN.

I HAVE been reading your Tobacco Column (call it tobacco pages) from the beginning. I feel like protesting a little at the enormous "cheek" manifested by some. For instance, "I began the use of tobacco three years ago, for the purpose of smoking bees, but," (hark at that!) "I found it injurious to my health, and I quit the use of it. If I am entitled to a smoker," etc. You surely did not send this man a smoker, for he was

compelled to stop on account of his health. Also the very next appeal is for an "Uncle" who quit seven months before, and who, no doubt, never heard of a smoker or your offer, but stopped for reasons best known to himself, and is now thrust forward to receive his reward for the self-sacrifice—a sacrifice which your "column" has not a thing to do with, as I understand it. As I understand the "column," those who read your offer, and will take advantage of your liberality, and eschew (and *not* chew) the weed (thus securing a smoker "without money and without price"), are the only ones entitled to a smoker.

A man who says, "I will stop the use of tobacco if you will send me a smoker," is entitled to your consideration; otherwise, as in the above two cases native sense is lacking, and a smoker doubtless thrown away. Note the language of S. C. Stone, page 634. There is hope of reforming him from the habit. Then notice another one on the same page, who, after more than three years have elapsed, swoops down, and grasps a smoker which would have been worn out had he received it when justly entitled to it over three years previously. I am as justly entitled to one, because I quit smoking 18 years ago, and I faithfully promise that I will never use the weed again. If I do, I will pay you for the smoker. I have several on hand, so you need be in no hurry about sending it.

W. M. YOUNG.

Nevada, O., Aug. 23, 1887.

Friend Y., there has been a little looseness, I admit, in regard to this matter of giving smokers to those who give up tobacco; but as the column is starting a great wave in the right direction, it seems to me we can not afford to seem to be small in the matter. But it is true, some of the friends have received a smoker for quitting a great while ago. By this act they become one of the great anti-tobacco band, and swell the ranks; for he who puts his name in print becomes a worker against the evil. I think, however, since you suggest it, that we had better say in the future, that smokers are only for those who give up tobacco because of having seen the Tobacco Column. We shall always be glad, however, to get testimonials from those giving it up because it was injurious to their health. If they have been benefited in health by dropping it, they surely ought to be willing to help others by standing up and testifying.

I need a smoker, and will stop using the weed if you will send it to me; and if I ever take another chew, or smoke, I will send you the cash.

E. A. BOAL.

Berrien Springs, Berrien Co., Mich., Aug. 16, 1887.

If you will send me a smoker I will quit chewing tobacco, or using it in any form; and if I fail I will pay you for the same.

M. R. W. PERRY.

Goodman, N. C., Aug. 9, 1887.

I have quit using tobacco. If you will send me a smoker I will pay you for it if I ever use the weed again.

T. L. CASE.

Lebanon, Mo., Aug. 13, 1887.

Below I give you the names of three friends who have quit the use of tobacco through the influence of GLEANINGS and my persuasion, and I ask for a smoker for each. If they use tobacco again I will

see that they pay for the smokers. They are Willie Weisenhunt, George Book, T. D. Page. If it is against the rules, or any thing wrong, I do not wish it.

W. W. ADDISON.

Bumpus, Ill., Aug. 9, 1887.

I shall make up my mind to drop the use of tobacco, if you will send me a smoker; and if I ever commence to use it again I will pay for two smokers.

LONZO MOSES.

Loretto, Minn., Aug. 3, 1887.

OUR OWN APIARY.

CONDUCTED BY ERNEST R. ROOT.

THOMAS WILLIAM COWAN.

THE editorial in reference to Mr. Thomas William Cowan, editor of the *British Bee Journal*, had hardly appeared in last GLEANINGS before the following card from Prof. Cook announced a proposed visit from Mr. and Mrs. Cowan:

My dear Mr. Root:—

Mr. and Mrs. Cowan arrived last Friday. They will leave here for your place some time next week. They are delightful people. I am enjoying them immensely. I am sure you will. Mr. C. is a very modest man, and yet I doubt if there is a man in the whole world who has such a literary culture in regard to bees. He reads most of the modern languages, which gives him a vast advantage. You may look for a treat.

A. J. COOK.

Agricultural College, Mich., Aug. 30, 1887.

Knowing that Mr. Cowan had made the study of foul brood, as seen under the microscope, a special study, I felt quite anxious to see him. Accordingly, having received a card from our distinguished visitor announcing the exact date when he would be here, I went over to the train, accompanied by Huber, followed shortly afterward by "his pa." "How will you know the gentleman when he steps off the car?" asked the eldest of the three Roots. "Know him!" I rejoined, "I feel sure I shall be able to pick him out, for I have seen a fine portrait engraving of him in the *Deutsche Illustrierte Bienenzeitung*, edited by C. J. H. Gravenhorst." Nothing further was said. Finally the train arrived, and, sure enough, I saw our friend step on to the platform, accompanied by his wife. I did feel some little hesitancy in addressing by name one whom I had never seen; but when I saw a large box, perhaps two feet high, and about a foot square (which I took for granted contained the large microscope), I stepped forward, and, touching the shoulder of the possessor of said box, said, "Mr. Cowan, I am very happy to meet you." I then met Mrs. C. I immediately informed them who your humble servant was, and then introduced them to the eldest and youngest Root. Together we started for the paternal mansion. That evening we discussed American and British apiculture.

Perhaps before we proceed further it may be pertinent to tell our readers more exactly who Mr. Cowan is. First of all, I will say that the whole Root family concurs heartily in all that Prof. Cook says in his card as

above. After a little talk and personal acquaintance, one can not help recognizing that the editor of the *British Bee Journal* has rare abilities. He is acquainted with almost every thing that has been written on bees, whether of the present or of the past. He is the possessor of one of the largest libraries exclusively on bees, in the world, some of the volumes being very old.* As he is able to speak in many of the modern languages, this library is something more to him than mere curiosity. He is well acquainted with the scientific investigations of the past pertaining to bees, and, guided by this, he is the better able to direct his own investigations. Aside from the field of microscopy, to which Mr. Cowan has given so many years of careful study, he has devoted considerable attention to geology and botany; in fact, we found it was quite difficult to find a plant of any kind that he did not know the name of.

In consequence of the senior editor's inability, resulting from ill health and the press of business, to entertain visitors, however distinguished they may be, I devoted my whole time to Mr. Cowan, for I felt that the opportunity was too rare to lose any of the advantages which I might obtain from his company; therefore I was with him the greater part of two days and two evenings. As the subject of microscopy used to be one of my favorite pastimes, I now felt the old enthusiasm well up as I began to talk with a man who had spent more or less of forty years in this interesting study. Accordingly, the next day he was solicited to show us his microscope and microscopic slides. When brother Jones, of the *Canadian Bee Journal*, stated that Mr. Cowan was the possessor of one of the finest, best, and most expensive microscopes in the world, I felt somewhat doubtful as to whether the Canadian editor was fully competent to decide what a good microscope is; but when our visitor drew his instrument from its box, and showed me the accessories, I was doubtful no more.

It may be interesting to some who have a partial acquaintance with the subject of microscopy, to describe briefly his instrument. It is a binocular, after the Beck pattern. It has a coarse and fine adjustment, substage, and a mechanical arrangement for moving the slides. It has several of the best eyepieces. In addition to these there is a nice assortment of the very finest objectives that can be obtained anywhere in the world—a 3-inch, 1-inch, $\frac{3}{4}$ -inch, $\frac{1}{2}$ -inch, $\frac{3}{8}$ -inch, $\frac{1}{4}$ -inch, and $\frac{1}{8}$ -inch. I presume that none of these latter could be obtained for much less than fifty or one hundred dollars in this country. More than this, he had a spot-lens, parabolic reflector, condenser, and polariscope. The whole instrument, including the accessories, would probably cost from one thousand to fifteen hundred dollars. As one views the microscope, and admires its beauty, he is greatly astonished to learn that the whole microscope, excepting the lenses was made by Mr. Cowan himself. I should judge that, if he were able to

* In order to give our readers an idea of Mr. Cowan's investigations in bee-lore, we would ask them to read an article from his pen, on page 446, 1884.

make such a beautiful instrument, it would not tax him very hard to be able to make the lenses. No one less than a mechanic of the highest order could execute such a piece of work.

The second evening, Mr. C. drew out his microscope and his collection of objects, nearly all of them mounted specimens of the different parts of the bee. I thought I knew something of the anatomical structure of our pets, and I thought my lenses and apparatus were quite sufficient for showing clearly their tissues and their structure; but when I looked at the same specimens prepared by himself, with the light from the parabolic reflector, I must confess that I never saw any thing quite so beautiful, so distinct, and so well defined. The most minute portions of the bee could be viewed as easily as you would trace and examine minutely the structure of your hand. At the time we had our Microscopical Society here in Medina, my instrument was counted one of the best; but when I viewed the same objects through my lenses—well, I just wanted a better microscope, to put it mildly.

Perhaps all this microscopic talk is not so interesting to our readers who have never had a taste for such things, or even an opportunity had they desired it, and so I will hasten to the microscopical appearance of foul brood.

BACILLUS ALVEI: IS THE FOUL BROOD OF AMERICA DIFFERENT IN ANY PARTICULAR FROM THE FOUL BROOD OF EUROPE?

Inasmuch as some authorities disagree as to the real nature of foul brood, its source, and method of cure, it has been suggested a number of times that the foul brood of America may be somewhat different from that which is found in Europe. Again, it is asserted that there is a mild and a malignant form of the disease, and that apiaries may be attacked by one or the other, or both. From the descriptions which I have read, and the symptoms which I have compared of foul brood as found in the different countries, I have been loth to believe that there are several phases of the disease. On the contrary, I felt pretty tolerably certain that there was only one kind of foul brood, and that that kind was as malignant as any one could possibly expect.

One of the things which I was very anxious to see under Mr. Cowan's microscope was the bacillus alvei, the scientific name for the germs of foul brood. I was particularly desirous of seeing the microscopic germs of the disease as it is in our own apiary, with a view of determining whether it was similar or dissimilar from the bacillus alvei of Europe. We first examined some prepared slides which Mr. Cowan brought with him—a $\frac{1}{2}$ -inch objective being used for the purpose. After having battled with this microscopic enemy for so long, and never having seen the actual thing itself, it was with no little degree of pleasure that I looked at the thing which has been talked about so much and so much discussed. Had I been working by myself with all the necessary apparatus, I should not have been at all certain; but with Mr. Cowan right [there

to tell me that what I was looking at was really the bacillus alvei, I felt satisfied, intensely so, for once in my life. Perhaps some of the readers may imagine that these germs possess form—have legs, eyes, and all that sort of thing. If they do, I must say they are very greatly mistaken. On the contrary, the bacillei have the appearance of a lot of miniature walking-sticks lying together here and there in the field of view. When I say "miniature," I mean they were small, or appeared small, even when magnified 3000 diameters. In the field of the microscope, at this power, as nearly as I could recollect, they appeared to be about an eighth of an inch long, and about as large around as a human hair. I am sorry we have not a good engraving representing them, but we hope before many days to give our readers a view of these peculiar "animals." Having examined the bacillus alvei of Europe to my heart's content, I hunted up a frame of foul brood, placed it in a close box, and presented it to Mr. Cowan. He examined the frame as well as the matured mass in the cells, and pronounced it to be the same as he had seen and experienced in his own apiary, as well as in the apiaries of others.

For the benefit of our readers interested in microscopy, I will give Mr. Cowan's modus operandi of preparing a specimen of foul brood, to be examined under the microscope.

He first called for a clean slide (a slip of glass one inch by three inches), and also for a very thin cover glass, as thin as this paper. These I supplied him with. He then dipped the point of his penknife into a diseased cell, drew it out, and placed it in the center of the glass slide. After spreading it he placed the glass cover over it and pressed it gently, in order to get all the excess of matter out at the sides. To make the bacillus alvei show more plainly, he next placed a drop of aniline ink at the edge of the covered glass—an operation called "staining." The ink, by capillary attraction, soon spread all through under the cover glass. The specimen as thus prepared was placed under his $\frac{1}{2}$ immersion lens. Examination showed that the germs which we saw were bacillus alvei, exactly like those we had just seen in a prepared specimen of foul brood from Europe. Mr. Cowan then prepared other slides in the manner I have described, and in all cases the bacillus alvei were seen.

I can scarcely think there is any possible doubt but that we have the very same foul brood that is found in Europe; and all the talk that we have had, to the effect that we have one form of foul brood and the Europeans another, is nonsense.

GOOD-BY!

Before closing, there are many more things I should like to say about Mr. Cowan and his visit. I will say this much, however: For one possessed of so many attainments, he is exceedingly modest. I don't recollect that he referred to himself or to his accomplishments, except in answer to direct questions; and even then he said as little as Yankee inquisitiveness would permit.

Just as he was stepping aboard the train,

after having spent two days with us, I said to him, "I presume you would have no objection to my writing this visit up for the columns of GLEANINGS."

He hesitated somewhat, and finally said, with a pleasant smile on his face, "No, if you don't indulge in American taffy."

"All right," said I, and the train pulled out as I bade him good-by. If, indeed, I have indulged in that truly American article, I sincerely crave his pardon; but I have stated only what I think all our subscribers ought to know.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER,
MEDINA, OHIO.

TERMS: \$1.00 PER YEAR, POSTPAID.

MEDINA, SEPT. 15, 1887.

Forgetting those things which are behind, and reaching forth unto those things which are before, I press toward the mark for the prize of the high calling of God in Christ Jesus.—PHILIPPIANS 3: 13, 14.

CITY COUNCILS VS. BEES.

A CORRESPONDENT sends us the following:

Our city council has ordered our bees removed out of the corporation by Oct. 30. What would you do about it? J. H. TATMAN, Connersville, Ind., Sept. 3, 1887.

Friend T., you can probably do nothing by yourself; but if you look on p. 578 of our last issue you will notice what the Bee-Keepers' Union succeeded in doing under similar circumstances at Ft. Wayne, Ind. I would advise you to write to Mr. Newman, the manager, for further instructions.

PRACTICAL FLORICULTURE; PETER HENDERSON'S NEW REVISION OF THE ABOVE BOOK.

It has been quite a treat for me to go through the above book, comparing the revised edition with the old one. The author has carefully gone over every line and every sentence; and not only has considerable new matter been added, but every change that recent developments have required has been carefully made. Sometimes a single word is inserted, sometimes a single word is changed, and, again, a whole sentence or paragraph. Some chapters that were in the back part of the book, which always seemed to me should have been in the fore part, are put where they ought to be. It is a great deal of work to do this, as any one who has tried it can testify. The price is still \$1.50, postpaid, as heretofore. We can mail it on application.

SENDING GOODS WITHOUT CASH, TO ENTIRE STRANGERS.

I SUPPOSE that most of the friends, of course, are aware that no sound business man is in the habit of doing any thing of the kind; but what I wish to consider now is, that there seems to be quite a large class of individuals who order goods without saying a word about their standing or responsibility, or even telling who they are, or giving any sort of ref-

erence. Of course, all we can do is to send them an estimate with a printed slip, saying we must have either cash or reference, etc. Now, a good many people write back that they have as good a right to say they don't know us as we have to say we don't know them. And at first thought, many, especially those young in business, might say there is justice in saying they have just as good a right to ask for goods in advance as we have to ask for cash in advance. To all such we beg to suggest that business men keep records that inform them at a glance who owns property, and who is entitled to credit, and who is not. These records tell, furthermore, what a man's habits are, therefore any one can ascertain at any bank whether it is safe to send money to A. I. Root or not, and the same with other business institutions. But the reverse of this is not true. Those who seek credit without reference or explanation, as a rule are not quoted anywhere, and we have no means of ascertaining what their habits may be, or whether they own sufficient property to be responsible for their contracts and agreements. Do you not see the difference?

SPECIAL NOTICES.

CALIFORNIA SAGE HONEY.

ALTHOUGH we are still out of clover and basswood extracted honey, we have about 10,000 pounds of California sage honey, in 60-pound cans, two cans in a case. If this continues to go off as rapidly as it has done the past few weeks, we shall soon be out of this also. Our present price of this is 8 cents per pound in original cases; single-can lot, 8½ cents per pound. In packages smaller than 60-pound can, 10 cents per pound, can included. These quotations take the place of all others previously made. Samples of this honey free on application.

WANTED—BASSWOOD AND CLOVER HONEY.

OUR offer in our last issue, of 7 cts. for basswood and 8 cts. for clover, has not yet brought us any honey, therefore we now offer one cent more. In other words, we will pay 8 cts. for a good article of basswood honey, and 9 for clover honey, delivered here. I am not sure, however, that we shall get any at this price; in fact, I rather hope we shall not, for I am pleased to see the price going up to a paying figure for our bee-friends. We propose, nevertheless, increasing our offer one cent at a time in each issue, until we get some. In this way we shall ascertain just what extracted honey is now worth, letting demand and supply fix the price.

I WILL give about three hundred dollars' worth of bees and bee-fixtures for a No. one buggy-horse. Address for particulars,

S. C. KIRKPATRICK, Hodgenville, Ky.

DADANT'S FOUNDATION FACTORY, WHOLESALE AND RETAIL.

CONVENTION NOTICES.

The Darke Co. Union Bee-Keepers' Society will hold its next meeting at Arcanum, O., on Friday, Oct. 28, 1887. J. A. ROE.

The presence of all interested is earnestly requested at a meeting of the Northern Ohio Bee-Keepers' Association, in the Town Hall, Wellington, on Saturday, Oct. 8, 1887.

H. W. MINNS, Sec.

The Pan-Handle Bee-Keepers' Association will hold its next meeting Oct. 26 and 27, 1887, in the K. of P. Hall, No. 1138 Main St., Wheeling, W. Va. All bee-keepers are invited.

W. L. KINSEY, Sec.

The North-American Bee-Keepers' Society and the Northwestern Bee-Keepers' Society will meet in joint convention at the Commercial Hotel, corner of Lake and Dearborn Streets, Chicago, on Wednesday, Thursday, and Friday, Nov. 16, 17, and 18, 1887. Arrangements have been made with the hotel, for back room, one bed, two persons, \$1.75 per day, each; for room, \$2.00 per day, each person. This date occurs during the second week of the Fat-Stock Show, when excursion rates will be very low.

W. Z. HUTCHINSON.

KIND WORDS FROM OUR CUSTOMERS.

The wheelbarrow is a dandy, and has saved Us & Co. many a backache, and will have paid for itself by the time snow flies next winter. P. SUTTON.
Exeter, Pa., Aug. 29, 1887.

Inclosed find postoffice order for three dollars, for which please send us one crate of Clark smokers. They are the best that have ever come to this country.

JOHN PYPER.

Nephi, Utah, July 18, 1887.

Inclosed find \$1.00, due for GLEANINGS, the best bee-journal published. Yes, I must have it. I can't well get along without it.

J. J. DARDEN.

Giddings, Texas, Sept. 15, 1887.

THAT LITTLE AD.

Friend Root:—I will send you pay for my advertisement that was inserted in GLEANINGS, Aug. 15, in Exchange Column. It has given me more correspondence than I can answer. Letters poured in from Florida, all the way to Wisconsin, except from Kentucky.

L. C. CALVERT.

Poplar Flat, Ky.

I will write you a few lines to say that I have found GLEANINGS a blessing to me, especially the parts headed *Myself and My Neighbors*, and *Our Homes*, and many other good bits of reading that I have been pleased more than a dollar's worth with, and would not like to be without it.

Burnt Mills, Md., June 14, 1887. J. HAMILTON.

THAT IMPORTED QUEEN.

The imported queen you sent is a "daisy," and is doing her work with the best of them. I had no trouble with her. She was laying in three days after I put her in the hive. Well, *friend Root*, you can imagine how proud I am of her, and I shall do my best to winter her and all the rest of them.

DR. L. L. LOOMIS.

Pemberville, Wood Co., O., Sept. 23, 1887.

THE CLARK SMOKER AND SAWDUST FUEL.

The Clark smoker works admirably with the shavings-like sawdust we get in making the white-poplar sections.

DR. G. L. TINKER.

New Philadelphia, O., June 21, 1887.

I have been sending you little orders ever since 1882. The goods have reached us always by the time the invoice did, and often before. Your goods have always been as good or better than you represented them, for which I thank you very much.

JOHN J. MATTHEWS.

Antimony City, Sevier Co., Ark.

The bees arrived Tuesday evening. I put them in with a weak swarm of black bees. They have passed one day of business in their new home, and seem to be all right. This has been my first effort in this line. If all goes right I shall be glad. I am a novice in bee culture, and this is my second season. I read the A B C, and feel stronger and more confidence in myself.

S. HOPKINS.

W. Walworth, N. Y., Sept. 6, 1887.

THE A B C BOOK NICER THAN EXPECTED.

(SEE P. 684.)

Your beautiful A B C book received. I asked for a paper-covered one, and you sent a cloth-bound one. Surely you speak the truth when you say you strive to give a little more than is expected of you; for even I, a beggar, got more. I should be ashamed to think I asked for the book as I did, if I didn't tell myself that, out of the very first profit I received from those bees, that book shall be paid for. I didn't expect it was half as large or half as nice or half as beautiful, any way, and I am very much obliged for it until you are better paid. If good wishes from a great many friends would only do it, I think you might visit your apiary to-morrow morning and find all trace of foul brood had left it for ever; but trouble will come, and usually for some good, but it is hard to believe it so.

MRS. C. PENNINGTON.

Cottage Grove, Minn., Aug. 22, 1887.

PLEASED: OUR MODE OF PACKING.

You will pardon my freedom when I assure you that your kind, pleasant, and instructive Home talks have made us all quite well acquainted with you. Will you kindly permit me to thank you for the beautiful bees and the careful manner of putting them up? also for the large handsome queen, whose agreeable acquaintance we made to day? Bees went to carrying pollen within 90 minutes after being released, and are so courteous, gentle, and, apparently appreciative of our attentions that I—well, I trust you will not think me idolatrous if I confess to having fallen in love with them. I fear we shall never be able to cancel all obligations, but hope to deserve your confidence *always*.

MISS DODY E. BEAUCHAMP.

Orange, Tex., Aug. 21, 1887.

Mr. Root:—Dody forgot, I presume, to tell you that the bees went from the express office, 8 miles on horseback, and the rest of the distance, 17 miles, on a small sail-boat, against a stiff breeze and heavy sea, and still seemed as if able to continue the voyage to Central America, if so required. Tennie, too, says thank you. If the bees die, it will be from overnursing.

W. A. J. BEAUCHAMP.

Orange, Tex., Aug. 21, 1887.

THE WINTER CARE OF HORSES AND CATTLE.

THE MOST HUMANE AND PROFITABLE TREATMENT.

By T. B. TERRY.

Although the book is mainly in regard to the winter care of horses and cattle, it touches on almost every thing connected with successful farming—shelter, comfort, feeding, exercise, kindness, different sorts of feed, with a full treatise on the most economical way of saving manure. A full description of Terry's model barn is also given.

Price 40 cts.; by mail, 43 cts.

A. I. ROOT, Medina, Ohio.

HONEY COLUMN.

CITY MARKETS.

BOSTON.—Honey.—Fair demand; retail buyers think price too high, and buy small. Our market has been brought into notice so of late by our high quotations, we thought best to write you and explain our position. With the short crop, we saw no reason why we could not sell to the jobbing trade at 20c, and to retail trade at 22c, and have sold nothing of fancy quality less than 20c this season. We have received a good many letters from all parts of the country, saying if we could get the prices we quoted, the writers would send us their honey; but we have written them that it was not advisable for us to have any more just now, as, if we should have it all come here, we should have to sell at 15c. Our advice to all is, not to hurry your honey to market. There can be none made until next season, and it will be all wanted at good prices before then.

Our neighbors are offering good one-pound sections at 18c, and it may be that it will be lower, so our quotations should be 18c@20c for 1-lb. sections; 17c@18 for 2-lbs. Extracted, 7c@9c.

BLAKE & RIPLEY,
57 Chatham St., Boston, Mass.

Sept. 21.

CINCINNATI.—Honey.—The demand is very good for extracted honey from manufacturers, who buy Southern honey principally. Only a few of our customers buy clover or other varieties, to suit their own flavor, for manufacturing purposes. There is also a very good demand for clover honey, in square glass jars, from the jobbing trade. Extracted honey brings 3½c@7c per lb. on arrival, according to quality. There is no new comb honey in our city, consequently we can't sell any, and it seems to be folly to make quotations. But we believe that a choice article of comb honey would bring 18c@20c per lb. in a jobbing way at present. This is more than it will bring about Christmas, if our experience of former years is a criterion to go by. You editors are wrong to advise our friends to hold on for higher prices. If we are wrong, let us know, please, in due time, and we shall acknowledge our error.

Beeswax is in good demand, and brings 20c@22c per lb. on arrival for good to choice yellow.

CHAS. F. MUTH & SON,
Cincinnati, O.

Sept. 20.

ST. LOUIS.—Honey.—We quote choice comb 13c@14c; latter is for choice white clover in good condition. Strained, in bbls., 4c@4½ cts. Extra fancy, of bright color and in No. 1 packages, ¼ cent advance on above. Extracted, in bbls., 4½c@5½ cts.; in cans, 6½c@7 cts.

Beeswax, 20½ cts. for prime.

Market very firm at above prices. Owing to the short crops reported everywhere, we look for a still further advance in prices.

D. G. TUTT & CO.,
206 N. Commercial St., St. Louis, Mo.

Sept. 22.

CLEVELAND.—Honey.—The market was never in a better state than at present; every lot is taken up promptly on arrival, at 18c for best white 1-lb. un-glassed sections; 14c@16 for 1½ and 2 lbs. Second grade and dark is not so active at 8c@12c. Extracted white clover, 8c. Basswood, 6c@7. Beeswax, 25c.

A. C. KENDEL,
115 Ontario St., Cleveland, O.

Sept. 20.

ALBANY.—Honey.—Market firm; think partly because of the reported short crop, causing a holding back, which makes receipts light. So far, we caution against holding too much. We quote white, 15c@20c; mixed, 12c@13; buckwheat, 11c@13. Extracted, white, 8c@10; buckwheat, 6c@7c.

H. R. WRIGHT,
328 Broadway, Albany, N. Y.

Sept. 22.

CHICAGO.—Honey.—The market has assumed a steady tone, and white comb in one-pound sections brings 18 cts. Something fancy, 20c, but there does not seem to be much of this grade. Two-pound sections, 16c. Extracted at 6c@8c. Beeswax, 22c@25c.

R. A. BURNETT,
161 So. Water St., Chicago, Ill.

Sept. 20.

COLUMBUS.—Honey.—The honey market is very firm, and none, scarcely, coming in. Parties from whom we hear, all speak of the great falling-off in yield, and all are either asking a high figure or unwilling to name a price. Others from whom we have heard throughout N. Y. State, will not fix a price until after their association meetings. We hope to be able ere long to name a figure for honey, and also a selling price. We are wholly unable to fill orders sent in, and must decline giving prices for awhile.

E. CLICKENGER & CO.,
Columbus, O.

Sept. 21.

KANSAS CITY.—Honey.—Our market is bare of comb honey, and the demand is good. We look for no lower prices, and they may advance two cents at any time. Choice white 2-lb. sections, 16c@17c; dark, 12c@14; choice white 1-lb. sections, 18c@20c; dark, 14c@16; California white 2-lb. sections, 16c@17c; 2-lbs., extra Cal., 13c@15; 2-lbs., Cal., 12c@13c. Extracted, choice white, 8c@10c; dark, 5c@7; California white, 8c@9; amber, 7c. Beeswax, 21c@22c.

HAMBLIN & BEARSS,
514 Walnut St., Kansas City, Mo.

Sept. 21.

NEW YORK.—Honey.—The honey market seems unsettled, as it is impossible to approximate the quantity now held in the country. At present we quote: Fancy white 1-lb. sections, 17c@19c; 2 lbs., 15c@16; fancy buckwheat 1-lb. sections, 12c@14; 2 lbs., 10c@12. Off grades, 1 and 2c per lb. less. White extracted, 8c@9c; buckwheat, 5½c@6; Southern, per gallon, 60c@70c. Beeswax, 22c@23c.

MC CAUL & HILDRETH BROS.,
28 & 30 W. Broadway, N. Y.

Sept. 20.

PHILADELPHIA.—Honey.—Fancy new white honey is in very limited supply, and far advanced. Inquiry is only for 1-lb. sections of white. Larger sections and dark goods are nominal as yet. We quote: New white clover, 18c@20c; buckwheat, 14c@16. Beeswax is in fair demand; prime yellow, 23c@25c; medium and dark, 18c@20; white (none offered) higher.

PANCOAST & GRIFFITHS,
122 Dock St., Philadelphia, Pa.

Sept. 21.

ST. LOUIS.—Honey.—Honey is scarce in our city—very little coming in, and stock so far is poor. Comb, choice, white clover, 1-lb. sections, 14c@15c; fair stock, 10c@12; low grade, 8c@9. Extracted, white clover, cans, 7c@8; fair, 6c@6½; Southern, bbls., 4c@5c. Beeswax, 20c@21c.

W. B. WESTCOTT & CO.,
108 & 110 Market St., St. Louis, Mo.

Sept. 23.

NEW YORK.—Honey.—Our market for honey is unchanged, with a good demand.

F. G. STROHMEYER & CO.,
122 Water St., New York.

Sept. 21.

DETROIT.—Honey.—Best white comb, in 1-lb. sections, 16c@18c. Beeswax, 23c.

M. H. HUNT,
Bell Branch, Mich.

Sept. 21.

FOR SALE.—Extracted white-clover honey in 120-lb. kegs, net, 10c. M. ISBELL, Norwich, N. Y.

FOR SALE.—700 lbs. extracted basswood honey, for \$75.00 in 100-lb. cans. Also 600 lbs. of box honey at 18c per lb. (100 lbs. of it in 1-lb. boxes); or the lot for \$180.00, crated and delivered on cars here free. The above lot is No. 1 honey, and well ripened.

F. M. WRIGHT, Enosburg, Franklin Co., Vt.

FOR SALE.—200 lbs. buckwheat and fall honey, in 1-pound boxes. If there are any who want this class of honey, will they please write me what it is worth to them?

WM. VANAUKEN,
Woodville, Jefferson Co., N. Y.

WANTED.—To purchase from one to five thousand pounds choice white-clover honey in one-pound sections. Crates to average about 25 lbs. each.

I. T. CARSON & CO.,
325 West Main St., Louisville, Ky.

15-20d

FOR SALE. Rubber-stamp apparatus cheap; size 4x6. Send for description and price to FOSTORIA RUBBER-STAMP CO., 19d FOSTORIA, OHIO.

DADANT'S FOUNDATION FACTORY, WHOLESALE AND RETAIL. See advertisement in another column.

Vol. XV.

OCT. 1, 1887.

No. 19.

TERMS: \$1.00 PER ANNUM IN ADVANCE; 2 Copies for \$1.50; 3 for \$2.75; 5 for \$4.00; 10 or more, 75 cts. each. Single number, 5 cts. Additions to clubs may be made at club rates. Above are all to be sent to ONE POSTOFFICE.

Established in 1873.

PUBLISHED SEMI-MONTHLY BY

A. I. ROOT, MEDINA, OHIO.

Clubs to different postoffices, NOT LESS than 30 cts. each, sent postpaid, in the U. S. and Canada. To all other countries of the Universal Postal Union, 18 cts. per year extra. To all countries not of the U. P. U., 42 cts. per year extra.

A VIEW OF THE OFFICE AT THE HOME OF THE HONEY-BEES.

SOMETHING IN REGARD TO THE BRAIN-WORK OF THE ESTABLISHMENT.

WE take great pleasure in giving you a view, a little further along, of our office as it appears almost every day. I have before given you sketches and incidents connected with the office work, so you already know something about it; and many of our friends not only feel familiar with our clerks by their signatures, but I presume they know most of them by their handwriting. Sometimes when visitors call they ask questions like this: "Will you tell me which one is 'Lu,' and where she works?" or "Is this Addie?" or "Bessie?" or expressions of a similar nature. Well, I am going to try to-day to introduce you, as well as I can on paper, to the workers in this department. There are in the room, I believe, twelve women and three men. Visitors often ask the question, why it is that our office should be so largely of the gentler sex. The answer I usually give is, that it is a great deal according to the law of the survival of the fittest. To be correct, however, I think I shall have to acknowledge that another item has something to do with it. During all my life, or, at least, of late years, I have tried to give work to those who seemed to need it most; and I believe it is true that it is much more difficult for a woman out of employment to find a place than it is for a man. A man can go and hunt work where a woman can not, or, at least, can not very well; so this has

something to do in regard to who shall have a place in our establishment, when there are so many constantly applying for places. But after all, it is those who are *faithful* that hold the places permanently. The Bible tells us, you know, that he that is *faithful* in little things shall eventually be intrusted with more important responsibilities; and this has been the case with us.

Perhaps the most important post in the whole office is that behind the wire railing, where you see four women at work at the ledgers, keeping accounts straight, and collecting. This is, perhaps, the real foundation of any business. If things are loose, and not attended to in the book-keeping department, the business will go down, no matter how well other departments may be managed. Miss Mason, who usually signs her name "M." in her correspondence, has the principal charge of the books. Three and sometimes four assist her in this work during the busy season. Right close by this desk with the wire railing around it, you will notice the door of the large safe, or vault. The books are all put in here over night, and taken out in the morning by the janitor. In fact, our ledgers are so heavy (including the \$75.00 index-book I have before told you about) that it would be quite a task for any woman to handle them all. This vault mentioned is one of a series of vaults in each of the three floors. They are built of such solid masonry that we expect them and their contents to remain uninjured, even should our whole establishment be destroyed by fire. All sorts of goods where there is much value in a small compass are stored in these vaults. The one that con-

tains the ledgers and other valuable papers contains pretty much all of the books we sell; for a good deal of money can be put in small compass where it is invested in books. Our book-trade is one large item of our business. In order to ship books promptly and rapidly, they are all wrapped up before being put away in the safe. Where the book is heavy, the corners are protected; and to avoid any danger of getting hold of the wrong book, the name and price of each book is printed on each outside wrapper. You may ask why we do them up until they are ready to send off. There are several reasons why. It keeps them clean, and free from dust. It is a saving of time; for the cost is comparatively nothing, where a clerk ties up books, having suitable paper, twine, and every thing in readiness, compared with wrapping them up one at a time. The lady standing up by the window, near the vault-door, is the one who has charge of the contents of the vault, mailing books, and, in fact, mailing almost every thing else. She is very careful and trustworthy in tying up goods securely and safely; and when complaints come in that somebody got the wrong book, or something was not tied up as it ought to have been, she has to take at least a part of the responsibility of making the wrong right. Her table is just back of where she is standing. In fact, I believe the photographer asked her to stand up and look this way when he took the picture. On her table will be found the very best kind of wrapping-paper, suitable twine, clasp-envelopes, strips of wood to put on articles that might be injured were they not strengthened, and all the paraphernalia needed to send almost any thing from the counter store below, over the mountains to California, or anywhere else where the U. S. mails reach.

Just in front of Mrs. Whitney is the desk where the clerk sits who opens the mails. Her sole business is to open each letter carefully, and note on one corner exactly what it contained; and if the contents are not exactly in accordance with what the writer claims to have sent, a printed postal is addressed him before the letter leaves her hand. If a man says he incloses a dollar, and she says that, when the letter reached her hand, it contained no dollar at all, there is a chance for quite a quarrel; so you see it is of the utmost importance that she mind her p's and q's; and if you were to go into this office you would find this clerk seldom speaks or seldom looks up at anybody or at any thing; and it is also her duty to place each letter, as it leaves her hands, under paper-weights (ready for my inspection) that indicate what department they are intended for. This latter clerk has also turned around in her chair, in obedience to the photographer's command. You see, he is "boss" for the time being.

Now, the desk right in front of this latter clerk, as she faces this way, the one covered with all sorts of traps scattered about promiscuously, belongs to A. I. Root. His chair is vacant, as you will notice; in fact, he never sits in it very long at a time, nor in any other chair, for that matter, unless it be where he is sitting at this moment, dic-

tating these lines to you. One reason why his table is in such disorder, compared with the rest, is, that so many matters are under consideration or awaiting the result of something else. Besides, a good many things are dropped on his table for inspection when he comes around. Last, and worst of all, there seems to be always a lot of things that he ought to attend to when he has a little surplus time or energy. On each side of his chair are rows of drawers. These drawers contain letters for the different departments of GLEANINGS. That is where Ernest goes when copy is wanted.

In the further corner of the room, opposite to the one occupied by the vault, is what we call the cloak-room. This is where the women-folks hang up their things, and where they go for a little seclusion any time they wish it. It contains a lounge, to be used in cases of indisposition. There is also a cupboard for rubbers. Mrs. W., however, whose work-table is right at the door of this room, complains that even among the women-folks the rule, "A place for every thing, and every thing in its place," is not always observed. This room also contains a wash-bowl and pitcher, and we are talking about having a marble-topped wash-stand, but we have not quite got around to it yet.

The clerk next to the cloak-room, facing this way, is the subscription clerk. She signs herself "Lizzie," and she has charge of every thing pertaining to subscriptions and advertisements. If in your order you say, among other things, "Send me GLEANINGS," the letter goes to her first; hence you see it is quite important that she should finish the letter quickly and pass it on to the express clerk or to the freight clerk.

The next one, right in front of her, takes all the letters ordering goods by freight. On a suitably printed blank sheet she copies off all the writer orders, taking particular pains to call a thing by the name it is called by in the price list, whether our customer observes to do this or not. If he omits prices, or gives them incorrectly, she corrects them. In fact, she condenses the order on this blank order-sheet in the fewest words possible, and yet have it plain for the packers. She also, by the aid of the Postal Guide and other books, makes sure the address is plain and correct, so you notice her place is quite responsible. Now, while women can do almost any thing that men can do, where they have had equal practice and experience, there is much of their work that needs a man's assistance and advice. Accordingly, a great part of the time you will see our friend John Calvert standing at her desk, with his hands full of letters. A great many times important questions in regard to machinery, the amount of power needed to drive it, the size of engine to be used, etc., are received. Questions of this nature make it necessary for us to hold a little council, as doctors do. In such cases, Mr. Warner, the foreman of the saw-room, myself, and Ernest also, advise in regard to the matter. The result of our decision is either verbally given to the freight clerk or dictated to one of the shorthand writers. The clerk at this desk of which we have been

speaking signs herself "C. K." During the busy season she has sometimes two assistants, and almost always at least one assistant. This assistant is seen with her back toward us. Either the photographer didn't call her, or else she didn't see fit to look around. She signs herself "Mattie;" and although she is younger than most of the others in the office, she has distinguished herself for remarkable accuracy and faithful attendance to her work. Whenever I hear too much fun going on in the office, consistent with the safety of our business, I never feel afraid that Mattie has any voice in it—that is, during working hours, and I believe this has much to do with the accuracy of her work.

them up. If they go to the wrong postoffice, or if she makes any sort of mistake in town, county, or State, she bears the responsibility. Goods that are needed almost every day are piled up on desks at her side, or before her. For instance, the A B C book, Terry's potato-book, smokers, and other things that are called for almost constantly, are already tied up, so she has nothing to do but to write the applicant's name and address on the package. Between these two last clerks, on one side, you will notice a couple of mail-bags. These are suspended by a sort of heavy iron bag-holder, and these bag-holders can be raised or lowered by means of a set-screw. After the mail packages are addressed, the proper amount of postage is put

OUR OFFICE: A GLIMPSE OF SOME OF THE BRAIN-WORKERS AT THE HOME OF THE HONEY-BEES.

Right back of Mattie sits another clerk also, with her back toward us. This is no other than our friend "Lu," who has been with us so many years that you almost all, doubtless, feel more or less acquainted with her. I presume the reason why she didn't turn around was because she is quite deaf; and if the photographer tried to make her hear he probably did not succeed. She has for years had charge of all our letters containing orders for goods by mail. She looks them over carefully, decides what to send and how to send it, and then the letter is given to Mrs. W., before mentioned.

The remaining clerk nearest us, with her face this way, is Addie. It is her business to address packages after Mrs. W. has tied

on by affixing stamps of different denominations from the stamp-drawer right at hand. When they commence filling the bags, the bag-holder is raised away up so the bottom is clear from the floor. When partly full, the holder is slipped down; and when the mail-boy comes for them at half-past three, the bag-holders are simply dropped down out of the way, and he comes down stairs pulling a bag after him with either hand. He has a wheelbarrow of his own, standing right by the outside door, unless somebody has borrowed it, and we have had some jangles and some loud scolding because, in spite of printed notices on the front board of said barrow, somebody persists in borrowing it, and then forgets to bring it back. If you

want to see how well I can scold, just take that nice light wheelbarrow, belonging to the mail-boy. When the mails are very heavy, he takes a horse and wagon.

And now we come to one of the shorthand writers. He is a brother of the proof-reader, whom I have several times mentioned, and, like this brother, picked up shorthand of his own accord, and became quite expert before hardly anybody knew it. He has not been long enough in the office to get as much acquainted with the office ways as the girls have; and there has already been some discussion as to whether any man would ever be able to manage our office business with as much care and neatness as the women-folks. I believe these discussions have, however, always been of a friendly nature; for although our women-folks belong to various churches, and have various opinions of their own, I don't believe we ever had one real live woman's-rights woman in our establishment.

The man sitting on the railing surrounding the opening that communicates with the counter store below, is Ernest. He is dictating to the shorthand writer who signs herself "N. J." She has for a great while written the greater part of our correspondence by means of the caligraph. She has been a great many years in our employ, and is perfectly familiar with almost every department of the business. She is remarkably quick and accurate; but she is not physically able to endure as much fatiguing brain-work as a good strong man. In these friendly discussions in regard to the ability of the two sexes, this question has also been discussed: "Has a woman the endurance that a man has for hard labor with mind or muscle?" Well, even if she has not, I have sometimes thought that a woman's quickness and intuition more than make up for her lack in strength; and even if such is not the case, I feel strongly inclined to give them the preference, other things being equal. I like to see our business prosper, and prove a success financially; but a hundred times more do I wish it may succeed in being helpful to my fellow-men and fellow-women. I believe, my friends, the latter have already demonstrated that woman is fitted for many places that she has not heretofore filled; and when my work is done here, I shall be glad to have it said of me that I had helped women to earn a livelihood where they were not situated so as to be able to help themselves.

Now, this room of which I have given you a view is a much longer one than it appears in the picture. The opening, through where the counter store may be seen below, is about twice as long as it appears in the cut; and through this opening we call to the clerks below, and they call to us above. As the view is given from the northeast end of this room, the east end is not seen at all; but for all that, a very important part of our business is located in this east end. It is the files of all our correspondence, that I have described before. The clerk who has charge of this department has been many years in the business, and we call her Kittie. She is expected to be able to produce any

letter that anybody ever sent us—that is, within three or four years back; for we sell our letters for paper-rags, after they are that old. Another clerk near Kittie takes charge of the express business, very much the same as "C. K." has charge of the freight department.

There is just one other individual I have passed by, and that is the little chap right under the opening, under the wire railing around the ledgers, and this is our four-year-old Huber. I presume he is asking the ladies if any of them can tell where his pa is; and I presume he is smilingly answered, as many another has been, over and over again, to the effect that the whereabouts of your humble servant is one of the problems "hard to find out." Sometimes they tell visitors, "If you look all over the grounds, and don't find him, you might go through all the different buildings; but as he is continually on the move, the chances are you will tire yourself out, and not get a glimpse of him, even then."

BEE-KEEPING IN CONNECTION WITH OTHER PURSUITS.

C. C. MILLER CONSIDERS AND SUGGESTS IN REGARD TO THE MATTER.

SHOULD bee-keeping be made an exclusive business, or should it be pursued in conjunction with some other business? This question can be best answered after considering some of the pursuits that may be combined with bee-keeping. I am competent to speak of only a few; and if it seems really desirable that there shall be a combination, perhaps others may be called out. Perhaps I may arouse Bro. G. M. Doolittle, by saying that I think he has made one of the worst combinations possible in combining bee-keeping with small-fruit raising. I think there is a somewhat general impression that bee-keeping and raising small fruits go nicely together. There is this much to say in favor of it—that the man with the right taste for bee-keeping is apt to have the right taste for a fruit-raiser; and if successful at either he would be successful at the other if he should turn his attention to it. But a business to be combined with bee-keeping should be one that would require the attention of the bee-keeper mainly at a time when his bees require no care. So far as my experience goes, the small-fruit business requires the closest attention at the very time the bees demand it. As soon as spring has fairly opened, there is work to be done at the bees, and so there is at strawberries, raspberries, etc. As the season advances, the bees become more imperative in their demands, and so do the berries. In the height of the picking season, when the eyes of the fruit-raiser must be everywhere to see that pickers are making good work, to settle disputes, to make sure that berries are promptly sent to their proper destination, and not allowed to lie over and spoil—at this time, when the fruit-raiser, unless possessed of a very cool head, is about half crazy, the bees alone are enough to make him go distracted when a dozen swarms may come out at a time. In a word, the busy time for each comes at the same time, and what is wanted is something to occupy the leisure time of the bee-keeper. Teaching school, I think,

comes nearer to it; for the busy time with bees comes in the summer vacation; and one with sufficient strength and the right taste might take care of quite a number of colonies without interfering with school duties. I think, however, he would in time decide as I did, to give up one or the other. A notable exception, however, is in the case of Mr. E. A. Gastman, of Decatur, Ill., who has been for many years superintendent of schools, if I am not mistaken, and at the same time a bee-keeper. Mr. Gastman, however, is a man of magnificent physique—by the way, it just occurs to me that he is very much the build of G. M. Doolittle—and looks as if he might easily do the work of two ordinary men.

Of course, there may be many special departments in which different individuals may have developed special taste and ability, where a somewhat successful combination might be made. For instance, the teacher of the old-fashioned singing-school (now unfortunately out of vogue) could take care of bees without interfering with his "schools," held only on the long evenings.

But what we are after is something that may be done by almost any one with the requisite qualifications to be a good bee-keeper. I think I have heard poultry-keeping spoken of in connection with bee-keeping. That, again, comes too much like berry-raising. When work begins to press with the bees, old Biddy will be wanting to sit, and perhaps two or three hens will be sitting on one nest, persistently changing from where you want them, till you feel like shutting your teeth together hard, and saying, "What does make you act so, when I haven't time to fuss with you? I should just like to wring your necks for you." Yet after all this is said, there remains the fact that, in at least two instances, periodicals have been published having for their specialties bee-keeping and poultry-raising. Why this, unless the two pursuits were supposed to have some special adaptation to each other? To tell the truth, if a young man to-day were to write me, "I have at least ordinary ability as a bee-keeper, and have decided I must have some other pursuit to connect with bee-keeping, what shall it be?" with my present knowledge I should reply, "Keep poultry." But I wouldn't have any hens sitting in swarming time, nor, indeed, with flocks of little chicks wandering about, trying to lose themselves in the wet grass. I have studied some little about it, and taken some observations; and I think the whole business of poultry-raising might be done almost entirely when bees require little attention.

Mind you, I don't say it is best to combine at all; but if combining is done, the merits of poultry-keeping deserve consideration. Others, perhaps, will favor us with their combinations.

Marengo, Ill.

C. C. MILLER.

Friend M., I have thought of this subject a good deal, and especially this matter of giving up every thing else and depending solely upon bees. If one has decided to do this, he should be very slow in making the change; and I would advise having capital enough in the bank, or somewhere else readily available, to take them through one or two seasons with little or no honey. Perhaps few know how many have got into trouble by depending on bees alone during the season that is just past. And there is another point: A young person with not

very much experience in bees or poultry either, would be pretty sure to neglect one or the other. Dividing the interest, with many people, seems to unfit them for what they might do well if their whole energies were given to it. Fruit-raising, or gardening and poultry-keeping, come in nicely, because one can be at home in the pursuit of all these industries. If the bee-keeper is employed by somebody else his time is not his own, and either the bees or his employer is apt to suffer. On the whole, I think it well for a bee-keeper to have a small piece of land, say five or ten acres; then let him manage his crops, or whatever else he does, so that it shall not absolutely demand his attention at the same time the bees do.

WHAT HAS THE HARVEST BEEN?

PROF. COOK GIVES US HIS REPORT OF THE SEASON JUST PAST.

WE have just put up our bees for winter. While they have given us very little honey (the least we ever got in any year since 1868, when I commenced keeping bees here), still they are in grand shape for winter—strong, healthy, plenty of young bees, and more than enough honey.

It will be remembered, that our bees are Syrian with several crosses of Carniolan. I went into Syrian exclusively when Mr. Jones first introduced them. I liked them; they were prolific, good to protect their hives, good to collect honey; but they were a little too irritable. I got a Carniolan of Mr. Benton some years since, and each year since have introduced some Carniolan blood. I now have two pure Carniolan queens in the apiary. The bees in general are quite yellow, showing the prepotency of the Syrian race; but they are also quiet, and really I like them much. I believe I am on the right track—any way, I shall keep right on, constantly breeding from the best.

A nephew, who has largely cared for his father's bees, helped me the other day. "Why," said he, "I never saw such pleasant bees to handle."

"Thank Carniola for that," said I.

I worked with them all the afternoon Saturday, with no protection, no bee-tent, and yet I got hardly a sting. Of course, robbing was started; but never fear robbing with good vigorous colonies of Syrians.

PROF. COOK GIVES APIFUGE A TRIAL.

Last Thursday I wished to work with some of the colonies; and as no other aid was available, Katie was my right-hand—manly girl. The day was quite cold and windy. Mr. Cowan had left me some apifuge; so I said to Katie, "We will try it." We both rubbed it all over our hands. Katie got one sting, and I got ten. The day before, I worked about the same time and got only four stings, with no apifuge, though the day was warmer. So much for apifuge. I did not use a bee-tent at any time.

Mr. Root, I wish to tender a vote of thanks to Mr. Cowan, from American—that means Canada also—apiarists. He was very thoughtful, and spared no pains that he might aid us to the utmost. I shall never forget his visit, and shall hope that it will be soon repeated.

HONEY-DEW, AGAIN.

Mr. J. H. Wood, Hammond, Ill., sends me a vial of honey which is evidently honey-dew, or secretion from plant-lice. It is not very unpleasant to the taste, but would not do to market. I do not believe that it is wise to use such honey for winter. Mr. Wood and several others have written me, asking whether I would use such honey for winter, and so it is a matter of practical interest. I have had bees gather quite a considerable lot of honey-dew from larch, which was very pleasant to the taste, and would injure no honey-market. Such honey seems to do no harm. Two years ago I received several samples of honey-dew, which had been stored by bees in our Northern-Michigan country. This was pleasant when first taken into the mouth, but was unpleasant soon after, and left a bad taste. I said I should try this if I had it, to some extent, though, of course, its use involved risk. It was tried, and proved disastrous in every case, so far as I know.

Let me add, that such terrible droughts as we have had the past season are very favorable to plant-lice (aphidae), and bark or scale-lice (coccidae), the very insects that secrete so much honey-dew. Again, such dry seasons shut up the nectar-glands of the flowers, and so the bees are ready for any kind of nectar; hence the double danger in just such seasons as this has been, and the need of extra care on the part of the apiarist.

Agricultural College, Mich.

A. J. COOK.

Friend C., it brought pleasant remembrances to my mind when you spoke of Katie. I have tried to tell our folks at home about your two children, and I think your expression describes her in some respects. She is strong and able. If she has not the strength of a little man, she has the good sense, and I noticed she was versed on many things that even women seldom look into. I suspect the reason is, because she is so much in the company of, and so extremely well acquainted with, her papa. I was pleased, during my visit, to note that both she and Bertie were able to converse on almost every subject their papa and mamma took up. What a pleasant thing it is to feel, that in each little home circle we are all one in our interests, our tastes, our pleasures, and our tasks!—I have been fearing, during this terrible drought, that we should have more honey-dew than ever before; but in our locality we have been happily disappointed. Very little of it has made its appearance.

OUR P. BENSON LETTER.

TESTYMOANYELLS TO P. BENSON A. B. S.

I HEREWITH present to my noomerous friends & admirers the followin galaxy of testymoanyells. They air entirely unsolisseted, the spontaneous outburst, as it were, of the emoshens of the hart. Thay will be found annex & subjoined heartwo as folloughs:

I have saw l of yure hunny boxes & I esteem it a grate invenshun, I shell never agane take up swarms with brimstone to get the hunny.

Bodderidono, Jan. 4, 1887.

G. M. DOOMUCH.

In the kuntry whair I was born, of whitc I was a native befour I cum to this kuntry, I never have saw a man I thot was the equill, I may say not even the soopeyver of P. Benson, A. B. S. I never herd of sitch a man thare. I doant beleave thair is sech a man thair. I am most shoof of it. If sitch a man is thare I wood of herd of it. I doant beleive thare is sitch a man on the face of the hole urth.

C. F. MOOT.

Sinsnatty, Feb. 30, 1887.

P. Benson, A. B. S. *Dear Sir:*—Yure foundashen is a grate invenshen. It is a long step in advants. In fact it is several steps in advants. Heretof we always poot our hives on the ground or hung them up on trees. This yeer we have poot a foundashen under each hive and it wurkx to perfeckshen. When bee-keepers see the advantage of it evry hive will have a foundashen bilt under it.

Porkilton, July 4, 1887.

C. P. NIGHTDANT.

I am very glad you conseved the idea of invertin hives. It will increase the produck 6 foaled & do away with the grate skureity of hunny.

Dewoodjack, June 31, 1887.

JAMES FOOTON.

Yure plan of counteractin the brude nest and makin the bees bild thair oan combs has been tride by sum of my nabers, and is a grate sucksess. You have my unquollyfide approvevle.

Vogersville, Oct. 4, 1886.

H. Z. WUTCHINSON.

Yure idee of gittin up a fackterry whare evry-buddy ken get all the bee fixins he needs is as use-fool as it is navvie. I hev often wundered that no-buddy thot of this before, for thare hed ot to be at leest 1 sitch place & and I think jist sitch a disinterested man as yourself, friend Benson, so modest & unassoomin, yet with sitch a vast scoop of intelleck is the rite man fur it. I will git oll my hives & things frum you.

A. I. BRANCH.

Medienow, Apr. 31, 1887.

I hev long felt the need of a noospaper whitch is all bees, & I feel sure you will make the most remarkable editior of the age.

T. G. OLDMAN.

Sheecowgo, Joon 31, 1887.

Much a steamed frend, yure projeck to lurn evry buddy how to keep bees in 6 short lessons without a master fills a akin voyed. I wood like fur straight to cum and wurk under you awhile & am savin up for it now.

A. C. JOOK.

Launcesing, Feb. 31, 1887.

I hev a hole trunk fool of sitch testymoanyells whitch thair izzent room to print them. Here is the trunk.

TRUNK FOOL OF TESTYMOANYELLS.

and you ken look them over at yure convenient.

P. BENSON, A. B. Sighentist.

MR. THOMAS WILLIAM COWAN.

A FEW WORDS IN REGARD TO HIS RECENT VISIT.

IT seems to me no more than fitting that we should take a little space to speak of one of the greatest of living bee-keepers. I do not mean by this that Mr. Cowan has the largest apiary in the world, for, in fact, I do not know how many colonies of bees he does keep. Furthermore, I do not know that he has ever made any money by following the pursuit of bee culture. It sounds a little strange, does it not, friends, to speak of it in this way? Well, the fact is, friend Cowan gave me a new glimpse of life; that is, he gave me a glimpse of the life of a human being who is not working as we Americans do, too many of us, simply to pile up dollars. I presume likely he is wealthy; but he did not tell me how much he is worth, and I did not feel like asking him. In fact, since I have been thinking of it, in our country we place altogether too much stress on the amount of property a man has laid up. In my Sunday-school class of growing boys a short time ago, the subject turned on wealth; and almost all of the boys, directly or indirectly, declared that money is the main thing. In trying to give them a glimpse of something better, I asked them how much they knew of Vanderbilt. They had heard his name mentioned, but not one of them could tell me much about him. I don't think that one of them knew whether Mr. Vanderbilt was dead or alive. They only knew that he had had the credit of being worth millions. Several years ago, while away from home, a locomotive and train of cars stopped at the station where I was standing. There was something so unusual about it that I inquired of a bystander what it all meant. He said it was Vanderbilt's traveling escort. He owned the cars and he owned the locomotive. We did not get a glimpse of the millionaire, but we did see his servants and waiting-men. They were fixed up enough to satisfy us, without getting a sight of the great man himself. Perhaps you wonder if a great crowd gathered. I don't believe that half a dozen people crossed the street; and although the train was evidently intended to impress the world on whatever road it ran, it did not seem to have succeeded at all. Nobody cared particularly about Vanderbilt; and the sight of this spectacle, indicating his princely wealth, gave me but a feeling of pain. I remember a gathering at a railroad station a few years after this. The gathering was to get a glimpse of Garfield. People came for miles around, and a great crowd surrounded the end of the car where he spoke to them during the brief interval the train stopped. The people flocked to see him, and to take him by the hand, as many as could, because he had risen from obscurity—yes, from being a canal-boy, by his own efforts and industry. Garfield was never worth very much money, I believe; but he won the love and esteem and respect of almost the whole world, because his life was given for the good of the people.

Well, in that two-days' visit with brother

Cowan I did not hear any thing said about great chances of making money, nor any discussions whether this, that, or the other would *pay*. It is sometimes said, that riches tend to discourage energy and industry. It has not been so in this case. Friend Cowan must have been all his life a most energetic and determined worker. I don't know how many people he employs, but I feel sure he might employ a great many if he chose. But the work I speak of is the work of his own hand and his own brain. When I met him at the train I offered to carry a part of his luggage, and I took hold of a nice square box that I thought would be just about what I should like to carry. I very soon, however, passed it over to Ernest. Had the box been filled with iron wedges, I should not have been more astonished. Pretty soon it transpired that this was his microscope. You know, friends, I have for many years worked in metals. I know pretty nearly how many years of patient, earnest toil it takes to make a fine mechanic, and therefore I was prepared to be surprised when Mrs. Cowan remarked that the microscope was the work of his own hands. The more I examined the instrument, the more astonished I became. People often say, in looking at home-made work like this, that it is wonderfully well done for *hand-work*; but this piece of machinery was the best work I ever saw in my life, of any kind. I mentally figured up the amount of machinery required for the different operations needed, and a little conversation satisfied me that he was expert in the use of the lathe and other mechanical tools. Those who use microscopes have doubtless discovered how necessary it is that every part of the machine should move freely, but, at the same time, should never move so easily as to move of its own accord. It never occurred to me, until I saw friend Cowan's instrument, that a device could be made to allow these heavy parts not only to move just right, but keep moving just right. Not only is every portion of the instrument adjustable in every direction, but the friction with which the parts move is also adjustable; and at any time any part can be made to work a little tighter or a little looser, by a slight turning of minute screws. A great many times I have felt impatient because of the length of time it takes to accomplish anything with the microscope, or to exhibit it to friends. Now, although this instrument is remarkably strong and heavy, our friend handles it with greater rapidity and accuracy than I ever saw anything in the line of optical instruments handled before.

Mr. Cowan was not only the most thoroughly versed man I have ever met or heard of in every thing pertaining to bee culture, but he was equally at home in the department of mechanics. At different periods of his life he has worked at or worked out most of the well-known mechanical problems. I was pleased to hear him tell us about working on perpetual motion, to be run by magnetism. He has made an electric clock, and one that performed well, too, which is more than can be said of the one that I made some years ago. He knew what is possible

in mechanics as well as that which is impossible. Now, do not think me vain when I say it is only once in a great while that I meet those who are capable of conversing in regard to the possibilities and impossibilities in the line of perpetual motion. If there are any among our readers who are now thinking or working on this foolish fancy, let me say to them, you can no more create a perpetual motion by cog-wheels and magnets than you can cheat the great Creator of the universe. You can make wind and water turn wheels, etc., and you can make natural gas run steam-engines, which ought to satisfy anybody; but we can not run any machine without motive power. People who talked about the Keely motor-power which made such a stir a few years ago, need a little rebuking in this line. At one time almost all the papers were against the *Scientific American* because that journal would not admit the claims made for the Keely motor. The *Scientific American* was at home; the matter came right on their own ground, and its editors knew whereof they spoke and wrote. The papers that published the accounts of its success ought to have known better.

Well, after talking a little on perpetual motion, friend C. said, with a bright start, "Oh! I have got a perpetual motion among the things I brought to show you."

He said it in an indifferent way that implied he did not expect it to run sawmills, thrashing-machines, etc.; but I was quite anxious to see it, nevertheless. Now, what do you suppose it was? It was in a microscope-slide that was prepared from an exceedingly thin bit of meteoric stone that fell to our earth in 1879, if I am correct. Pieces of the stone are ground so thin as to be transparent. This transparent film of meteoric stone is then subjected to the enormous magnifying power of something like 5000 diameters. I presume that earnest seekers for what God has given us to hunt out, placed this stone under the microscope to see if they could tell about where it came from, or what there was curious in regard to it. In this thin film of rock they found cavities. These cavities are full of liquid. Now, mind you, the stone, when it fell to the earth, was red-hot. How can the liquid be found there now? No one can tell. Well, in this liquid is a little bubble resembling an air-bubble in microscopic work; and this minute bubble, almost as small as any thing in the shape of insect-life can exist, is continually bounding and rebounding from one side of the cavity to the other. It seems as if it were almost alive, for it is never still. Now, an ordinary observer who has not studied the problem of perpetual motion, probably would not see any thing curious or wonderful about it; but it was to me at once one of the greatest curiosities of my life. Why should this bubble keep moving? It does not take any power to move it; in fact, the breath that stirs the wing of an insect would be a hurricane, almost, compared with the small amount of force needed to keep this tiny speck bumping around. The question is, What force keeps up this motion? It is at present one of the curiosities

of the scientific world, because there is absolutely no force known to man that will account for the motions of this uneasy little atom. Does it run all the time? Friend C. said it had always been running since it had belonged to him, and that he had watched it for hours together, to see if he could discover any thing that might give any possible clew to the propelling power. There is only a limited number of these microscopic curiosities in the world, and they are sold at a very high price.

Friend Cowan took a stroll in our grounds. He named the plants of America—that is, giving them their botanical name—about as easily as you would name the plants in your own garden. I presume many of the plants he had never seen before at all. We occasionally meet men who are deeply versed in regard to botany, entomology, astronomy, mechanics, or the fine arts; but it is very seldom indeed that we meet an individual who is sharp and keen on *all* these things. Friend Cowan seems to have cared to explore all Nature's labyrinths and resources; and, mind you, these explorations have not been made principally to satisfy his own notions: the end and aim of his work is for the benefit of his fellow-men. In our issue for May 1, p. 366, we made mention of a couple of pamphlets. One of these tells how to make an extractor and a bellows smoker; the other is in regard to securing extracted and comb honey, and the prevention of swarming.

Some one asked whether he should call friend C. "doctor" or "professor." He replied quietly, "Neither, if you please." But I see on the Guide-Book Pamphlets the following letters: F. G. S., which means, I presume, Fellow of the Geological Society; and F. R. M. S., which I also presume stands for Fellow of the Royal Microscopic Society. And last, but not least, he is editor of the *British Bee Journal*; and it seems to me it is not only the people of England who are to be congratulated upon their having such an able man, but I feel sure that the whole world will be better for his labors and researches.

Friend Cowan is a member of the Church of England; and it was not until I hunted up some of his old letters that I discovered what a very earnest, pure-minded, and high-toned Christian he is. Since I have seen the man, and talked with him face to face, the letters he has written to me in years past have a new meaning; and I presume, dear friends, such might be the case with many more, if it were possible for me to meet you all face to face; and while this is not possible in this world, who knows of the possibilities in that life over and beyond this? For we are sure that "eye hath not seen, nor ear heard, neither have entered into the heart of man, the things that God hath prepared for those who love him."

Now, dear friends, do not think that I mean to forget his good wife, who has been all these years by his side, a faithful student and patient helper. What friend Cowan lacks in the way of volubility, his wife makes up by her good-natured vivacity. Mrs. Root was greatly worried, as a matter

of course, at the thought of entertaining such distinguished guests; but Mrs. C.'s good-natured English ways very soon won a place in Mrs. Root's heart. In addressing her husband, Mrs. Cowan says, "Tom, dear," in a familiar way that was worth ever so much to me. For several days after they went away, my wife would have it over. This single little expression contributed greatly toward making us feel at home and acquainted. May God bless our two English friends wherever they go; and I presume that one secret of their vast fund of information is the fact that they have both traveled much.

A HOUSE-APIARY, AND ONE THAT IS MANAGED SUCCESSFULLY.

A COMMUNICATION FROM THE INVENTOR OF THE PEET QUEEN-CAGE.

WITH a good deal of pleasure I had been contemplating a trip to the above apiary for some time, remembering a similar visit about two years ago. Blue-Point Apiary is owned by Mr. M. G. Young, of Brooklyn, N. Y., and is located at Highland, Ulster Co., N. Y., a beautiful village nestling among the hills that overlook the grand and beautiful river Hudson. To get to Highland from New York you have your choice of three routes; viz., West Shore R. R., N. Y. Central R. R., and steamboat "Mary Powell." The latter was my choice, as I am passionately fond of sailing, and a brief respite from the dust and dirt of the city and its legion of railroads was a recreation of itself, and I appreciated it fully as I sat upon the deck and drank in the delightful breeze that fanned our heated bodies, which were almost cooked by the long 96° in-the-shade stretch of weather. But our bodies, being a good deal like the weather in our climate (very elastic), it did not take long to cool them off, and make us begin to feel a little uncomfortable the other way; however, this condition is easily remedied by simply walking inside the cabin, and accommodating yourself to a luxurious chair. This is just what your humble servant did, and spent the remainder of the steamboat part of the journey in admiring and studying human nature as it is phased among a promiscuous crowd traveling for pleasure on the Hudson River. I could write some very amusing notes of observation in this line, but it would be out of order in this article.

On taking a tour of observation now, I found we had gotten as far along as Newburgh; and being reminded by the inner man that it was time to attend to his wants, and that I yet had time before arriving at my get-off place to do so, I repaired to the lower deck, or cabin, where I found the required refreshments; and with an appetite made keen by the bracing mountain air, satisfied that inner man to the astonishment of my pocket-book.

Soon we arrived at Poughkeepsie, where I was to leave the steamboat and take (or let it take me) a small steam launch, or ferry-boat, and cross the river to Highland. Arriving at the dock, my good friend was awaiting me, and right glad I was to find him there; for the night was dark and the country strange, and his home some two miles from the river, necessitating a walk through the woods by path and road, up hill and down—mostly up; but following close to my friend Young, who seemed to be

perfectly at home among these hills, we soon arrived at Blue-Point Apiary, the writer about "played out," and ready to seek the welcome cot, where we were soon ensconced; and, listening to the monotonous music of the katydid, we soon slept the sleep of the weary, awakening only when the light of the coming day shone into my room, and the sound of nature's orchestra falling upon my ears. I was soon into my clothes, and out enjoying the loveliness of the country, as only a city clerk can appreciate to the full.

After breakfast, a visit to my friend's pets, the bees, was in order. Mr. Y. is thoroughly a house-apiarist. He hasn't a colony outside of the house. He has two bee-houses, situated about half a mile apart, one accommodating about thirty, the other twenty. The hives are arranged inside in two rows, one on the floor, and the other about four feet above, and occupying two sides of the house, viz., south and east. Experience has taught him that they do not winter well facing the north. The plan of the bee-house is about as follows: Shaped as an L, say 20x14 ft.; this gives him a room on the 14-ft. side for a work-room, about 8 ft. square. The sides opposite the hives are used to store frames, boxes, etc., and to hang up tools, etc., necessary for the apiarist. There is a skylight in the center of the roof, arranged with a wire screen that can be turned over at will by pulling a string. The object of this is twofold. First, it catches all the bees that fly off while manipulating the combs; it also prevents robbers from coming in, and holds them till the manipulator is through with that hive, when a pull of the string turns them all outdoors.

Another advantage, and a big one, for Mr. Y., is in having his bees all in a bee-house. He can go away and leave them locked up, and nothing can meddle with them. He uses a box 3 by 4 inches, with a full-size sheet of fdn. (flat bottom), fastening it with a Mallory fastener. He markets the honey himself; i. e., he seeks a market among grocerymen in Brooklyn, who pay him a good price, appreciating the neat box and clean tidy-looking crate that holds them. Mr. Y. is very successful in wintering his bees just as they stand in the bee-house, simply packing them with chaff or chaff cushions, allowing the entrances to remain open. He has a plan of ventilating the hive, which I will not explain here, as he may not wish me to do so. Mr. Y. has met the foul-brood problem to his sorrow, but he came off a conqueror, I think he said by the Muth system. He could give you some rich experience in that line, if called upon. He has now a very handsome strain of bees, whose qualities for working and gentleness are unsurpassed. Mr. Y. enjoys this little side business very much, as does his wife also, who helps him in a good part of the work. His vocation in Brooklyn being a schoolteacher, he has one day of every week at his disposal, as well as a long vacation in summer, at the beginning of which he moves at once with his family to his Highland apiary, and gathers new strength as well as new honey and ducats, to spend in the winter campaign for souls, for I forgot to tell you that Mr. Y. is the leader of a large mission school, also in Brooklyn. Like the bees he loves, he is a worker.

From Blue-Point Apiary I crossed the old Hudson again, and sought the "Knickerbocker Bee-Farm," located at Pine Plains, N. Y., an account of which I will give you later.

THEO. O. PEET.

Arlington, N. J., Sept. 7, 1887.

AUSTRALIA AS A BEE-COUNTRY.

ANOTHER STATEMENT.

YOUR issue of May 15, 1887, contains a letter from Mr. L. Chambers, lately a South-Australian bee-keeper and manufacturer of apicultural requisites. The tenor of his letter would lead your readers to suppose that bee-keeping in South Australia would be an easy and extremely profitable business. I am sure, from my personal knowledge of Mr. Chambers, that he would not willfully misrepresent our facilities and difficulties in bee-keeping; but his natural enthusiasm has led him into one or two errors which I am desirous of correcting. Our season certainly lasts four or five months; but the honey-flow during that term (except in a few favored localities) is spasmodic and irregular. As to our having no winter—well, compared with your winter, of course, we can't call our wet season a winter; but the last three or four months have proved that we get sufficient cold and wet to stop all brood-raising in Italian stocks.

Mr. Chambers quotes the "red gum" as a producer of many hundred-weights of honey per season. Well, sir, it seems to me a difficult job to give you any thing like a true estimate; but I certainly should like an acre or two of those several-hundred-weight trees in my neighborhood. I think your query as to one hundred pounds per tree is much nearer the mark.

The Italians and their crosses are proving much superior to black, and we are specially favored in having an island set apart by our legislature, for raising Italians only. With regard to that pest, foul brood, nearly all bee-keepers here have had some experience with it; but I never yet met one who had cured it by three sprayings with phenol. As an eradicator of the disease, most of us have found phenol useless; as a preventive, especially useful. Mr. Muth's method with salicylic acid is advocated here, and I personally have found it successful. Mr. Chambers' estimate of 400 or 500 lbs. per colony per season is often realized here; but in most districts, I venture to affirm that that result is exceptional. I append some reports culled by me from a number sent in by members of our bee-keepers' association, and you must understand that they are selected, and do not represent average reports.

TABULATED REPORT OF SOME OF THE BEST YIELDS IN AUSTRALIA.

Number of colonies at beginning of season.	Natural and artificial swarms during season.	Pounds comb honey taken.	Pounds extracted honey taken.	Total.	District.
3	16	210	3360	3570	Mt. Barker Springs.
1	2	267	—	267	Border Town.
1	14	590	1395	1985	Mount Parker.
1	12	700	781	1481	Mitcham.
6	21	1320	—	1320	Humburg Scrub.
3	8	107	512	619	North Adelaide.

The increase mentioned in the second column represents natural and artificial swarms from colonies mentioned in the first column.

With Mr. Chambers, I glory in saying that we have a capital country for honey-producers; but I must also admit, that, like every other country, we have difficulties—bad seasons, and plenty of hard work, before we can have or expect success.

With regard to my own bee-keeping doings, I am not a professional. My bees afford me constant

pleasure, and are, in fact, my hobby; but I must tell you that I find it a hobby that pays its own way, and the last report in the foregoing list is my own.

FREDERIC A. JOYNER.

Adelaide, Australia, July 18, 1887.

Friend J., we are under obligations to you for giving us actual figures in regard to this matter of yields of honey. Thanks, also, in regard to the reports about foul brood. I believe your experience just about agrees with that of Mr. Cowan, as given in his recent visit.

HOW A BEGINNER MADE BEES PAY.

A VISIT TO MRS. CHADDOCK'S APIARY.

MR. ROOT:—I am a beginner in bee culture. I want to tell you my little experience in connection with the work. To begin with, I will tell you that, for the past seven years, I have been living in a country home in Appanoose Co., Iowa, the land of white clover and honey. Three years ago last spring, George B. Replegle, whom I had the good fortune to claim for my neighbor, presented me with one colony of bees. I must confess that I had always gazed at the little creatures with a suspicious eye, and was quite unwilling to approach them. Their actions in the past had not impressed me favorably at all times. But I am always glad to form new acquaintances, and so I determined to become better acquainted with these busy little workers which I now had in my possession, and had allowed to be sheltered in one corner of my front yard.

Their former owner, knowing that I was entirely ignorant of the manners and customs of the bee-tribe, kindly took upon himself the task of instructing me in regard to them, and it was not long until friendly relations were established between us. Well, with occasional lessons I succeeded in managing the inmates of the little dwelling, and prevented their swarming, not wishing more than one colony until my knowledge was extended somewhat. I began a course of reading in *bee-ology*.

Mr. Replegle loaned me the A B C book, also GLEANINGS. I read them with much interest and profit. The following year I went on reading, and the bees went on working. During the summer they increased to three colonies, and, to reward me for my protecting care over them, they gathered in a surplus of honey which tempted me, when I discovered that I might convert the gift they had furnished, into silver. This I did until I found, on counting the pieces, I had sold six dollars' worth of honey.

Last season I increased to eight colonies, and realized \$12.00 from the sale of honey, besides having all the family wanted to eat, which was not a little.

Last spring I sold out, preparatory to moving to Illinois, where I expect to make my future home. My bees brought me between thirty-seven and forty dollars. I felt amply repaid for the little care I gave them, and must say that I am glad for having had the opportunity of forming an acquaintance with the bee-family. I take great pleasure in working with them, and have overcome the nervousness and timidity which I felt at first.

A short time ago I had the pleasure of visiting the apiary of Mrs. Chaddock, who lives about twenty-five miles from my home. I found her sit-

uated in a beautiful country. I had always enjoyed reading her letters in GLEANINGS, which I took one year while in Iowa; and while reading I formed an opinion of the writer. I found her to be just as I expected—get up and dust—willing to let her light shine. She took me out to see her bees, showed me the hives and fixtures she had gotten of you. I found many objects of interest at her beautiful home, which indicates that she has not been idle, and I hope she may live long and have health to enjoy the fruits of her labor.

As I have been suffering so much lately from rheumatism I have been to a great deal of expense, and did not feel that I could spare a dollar for GLEANINGS. Mrs. Chaddock kindly gave me some of hers and other late bee-journals to read. I have been offered, since coming to Canton, ten colonies of Italians to work with next year on shares. Every thing is to be furnished me—I to do the work, and to receive half the honey and half the increase. I can have them two years. Do you think that a fair offer? Should I move them this fall, or wait until spring? They are in Langstroth hives.

MRS. R. J. CURRY.

Canton, Fulton Co., Ill., Sept. 12, 1887.

If you want my opinion in regard to taking bees on shares, Mrs. C., I don't believe that any one who has had the success you seem to have had can afford to do any thing of that sort. Buy your bees, even if you buy only a couple of colonies to commence with. If, however, you prefer the "shares" plan, the offer you mention seems to be a good one. As you state it, I believe I would move them this fall.

FOUL BROOD "ACCORDING TO HOYLE."

SOME FURTHER SUGGESTIONS AND THEORIES REGARDING THE DISEASE.

IT is with the greatest degree of interest that I read your experiments with foul brood, given in each issue of GLEANINGS. I am glad to see you so cautious in coming to a decision as to the nature and cure of this disease; as your conclusions, right or wrong, will have great weight with the fraternity. Although you are very conservative on the subject, I conclude, from deductions you have made, that you are biased in favor of some theory. This is what I refer to. When the disease disappeared from your apiary, you thought you had cured it. Naturally; but when the disease reappeared, you gave it as your opinion that the disease had been covered up all that time, and that when you let them get near the starvation-point they got down to the disease. Now, is this conclusion supported by any thing we know, or have reason to suppose concerning the disease? I think not; any way, I want to reason with you on the matter.

We will suppose, for the sake of argument, that bacteria is the prime cause of the disease, and that it is conveyed in the honey. It is natural to suppose it gets in the honey when the honey is placed in cells where diseased larvæ had been. Suppose such were the case, would they not have eaten the affected honey first? Or let us suppose that the affected honey was some you had fed them, and it was all placed up next the top-bar, would not the top-bar have been reached in some combs in the apiary

long before the disease reappeared? Well, you will say, how did it reappear? Not being there, I could not say positively, and I don't know that I could if I were there; but from what you said at the time, I should judge that the larvæ in the hives affected were neglected by the bees, and, being weak for want of sufficient food, were attacked by bacteria. Bees will not feed the larvæ plentifully when their stores are low; and before they use it all they will quit feeding them and move them from the hive. When foul brood is in an apiary, and it is not so bad but that you can distinguish a difference in some colonies, these are the colonies which have it worst, other things being equal: Artificial colonies, where the larvæ are out of proportion to the nurse-bees, and get insufficient attention; where there is a puny queen; where there is a drone-layer or fertile workers.

You have evidence enough in GLEANINGS that the disease sometimes gets well of itself; but you believe in the germ theory, and you call such cases a "mild type." There is only one way to distinguish the mild type (?) from the genuine foul brood: The former gets well, the latter doesn't. That is the only difference. There is no doubt but that the larvæ of the former are killed just as dead, and in as great a proportion, and smell equally bad as the larvæ in a genuine case, other conditions being the same, of course. There are as many different phases of this disease as there are different causes, which accounts for the different descriptions of it.

I had the disease this last summer in my Whistler apiary (that which I had two years ago was in Mobile), that surpassed any case that I can call to mind. The disease reached its height of development in two weeks; that is, the combs containing larvæ were turned a bluish black. Even theappings were stained through. I do not believe over 25 per cent of the larvæ hatched. If this state of things had continued two months they would have all died. In that event it would have been a genuine case; as it was, it turned out to be only a mild type(?). It was very dry, and the bees were gathering honey-dew; the spring flowers had ceased to bloom. There came a good rain, which stopped the supply of honey-dew, and they, having very little in their hives, and plenty of nectar stored, gradually got well. Of course, if they had gathered considerable of that honey-dew, and it was not taken away, it would have been fatal. Bad water may have assisted in causing the disease—I can't say; but any way, I can't help believing the rain saved them.

I see you have a friend investigating the subject with the microscope. I hope he will be successful, and tell us something new about it. Now, if your friend were a first-class chemist as well as a microscopist, and would use both sciences in his investigations, I have no doubt but that he could tell us, very soon, something new and valuable; but with the microscope alone I hardly think he can do more than verify the experiments of Cheshire and others.

Through the chemists we learn what to eat, what to give our horses, cows, hogs, chickens, etc. They could tell us, no doubt, what foreign substance there was in the honey that caused bad results, or tell us if it lacked some essential thing. When bees are fed phenol, probably a chemist could tell us what percentage it was to the juices of the larva by which it was received. If he could learn that, he could easily tell if carbolic acid would cure the disease, by putting the same proportion in the compo-

sition in which he raises bacteria. That is, of course, if bacteria were the prime cause of the disease; but I think you will conclude before long that it is not. I hope so, anyhow. GEO. H. HOYLE.

Mobile, Ala., Sept. 10, 1887.

Many thanks for your kind words, friend H. It is true, I am conservative on the subject of foul brood, and it is hard for me to be otherwise; but I am not biased in favor of some theory. So many theories that I have entertained in regard to foul brood have been overthrown by some developments in the apiary, that I haven't thought it advisable to be guided by any of them to any great extent, however plausible they may have seemed. When the disease disappeared and then broke out after a period of six weeks, I inferred that the germs had been covered up, and then, as the stores of the bees began to decrease, said germs were uncovered, and so gave rise to the reappearance of the disease. This inference I made because others had said the same thing. Now, I don't know that this conclusion is supported by any thing that we *know*; in fact, there are very few things indeed that we *do know* positively about foul brood; but the development of certain facts often leads us to draw certain inferences which may be entirely false. You propose another theory for the entire absence and final reappearance of foul brood—that, in consequence of decreasing stores, the bees neglected the larvæ. The latter, thus weakened, were made more susceptible to the germs of the disease, which were probably present all the time; but as the larvæ had been previously kept healthy, they were enabled to throw off the influences of the disease. I am aware that a person in perfect health can enter infected districts with very much less liability of catching contagion than one who is less strong and less healthy. In the absence of more positive facts and data, I shall be just as ready, and perhaps more so, to accept this explanation than that the bees had eaten their stores down to the point where foul-brood germs existed.

I know that it has been suggested that there is a mild and a malignant form of foul brood—the one curable and the other incurable. From *Our Own Apiary* of last issue you will see that I express myself rather decidedly that such is not the case. I did so, however, because of what Mr. Cowan had said. Mr. C. has been all over the world, and has examined microscopically specimens of foul brood in his travels, and yet he finds that the bacillus alvei are in all cases identically the same. I know there is, apparently, a mild and a malignant form, and I have noticed the same thing among our bees. In one colony the disease will make rapid inroads, the brood becoming rotten within ten days from the time the disease made its first appearance. In another colony I have noticed only an occasional diseased cell, sometimes all trace of former infection being gone. Such colonies I have left to themselves, to see how it would turn out. Sometimes the disease appeared, and then it would disappear for a period of perhaps two months, at the end of which time an examination showed an occa-

sional cell of foul brood. Now, I can not help but think that the disease was identically the same in both the mild and virulent attacks. In the former, the bees strove so vigorously against the inroads of foul brood that they were enabled to keep it subjugated. In the latter, while the disease made rapid advances, the bees seemed to give it up as a bad job, from first to last. Why this difference? The most probable explanation, and the one which I think by far the most satisfactory to my own mind, is this: In those colonies where the disease seemed unable to make a very bad start, I observed that there was a very large number of young bees. Noting this fact, I told the boys to put a frame or two of hatching brood in the colonies which were most diseased. What did those little fellows do when they hatched out? Just as soon as they began to assume their duties as nurse-bees, they cleaned the combs up nice and sweet. We found that a frame of hatching brood did, in every case, make a vast difference in the amount of foul brood in the hive. Some might suggest, "Why would not this be a good way to cure foul brood?" It would, for the time being; but the trouble is, that, after these combs are nicely cleaned out, eggs, larvæ, and sealed brood nicely under way, three or four combs will become diseased. If, on the contrary, a frame of hatching brood were given to the colony at regular intervals of, say, once in three weeks, the young bees will keep the hive in pretty respectable shape. In a word, then, I think the reason why the disease makes greater inroads in some colonies than in others, is because of the addition in energy of the bees, and also upon the quantity of young bees present.

In all cases of foul brood that we have had in the apiary, we have never had more than two cases which cured themselves absolutely, and these may yet show their former infection. These colonies, however, never let more than three or four cells remain diseased in the hive at a time.

In regard to your last point, Mr. Frank Cheshire is positive that the bacteria are the prime cause of foul brood. Mr. T. W. Cowan is not so sure of it. He says that the fact that these bacteria are always present is not necessarily a proof that they are the *cause*. But this is a question for the doctors to settle.

BEE-HUNTING IN TWO CHAPTERS.

CHAPTER I.

VALUABLE FACTS ON THE SUBJECT.

IN presenting this subject to the readers of *GLEANINGS* I shall attempt to present only my ideas and methods. Perhaps some of the older bee-hunters who read this may have a "better way" of their own. Some thoughtless persons denounce bee-hunting as the work of a lazy man. I beg to differ with them. The successful bee-hunter must be a careful, observing, and persevering man. Bee-hunting may not pay financially; but a few days during vacation, spent in rambling through the woods, will have a beneficial effect up-

on our health, well worth the seeking. Many times I have found a natural curiosity, or a rare flower for analysis, which well repaid me for the day's tramp. Again, when I commenced bee-hunting I was so ignorant about bees that I thought they carried honey on their legs, and gathered wax from flowers. I took a colony from the woods, and began studying them. The result is, that to-day I am a full-fledged bee-keeper, and am very thankful that I learned to hunt bees.

GOULD'S BEE-HUNTING BOX.

Some hunters prefer very simple arrangements for hunting bees, such as a plain box or a tumbler, and a piece of comb. The box shown in the A B C may do very well, but I could not content myself with any of these. My hunting-box is $5\frac{1}{2}$ by 10 by $5\frac{1}{2}$ inches deep, and is made of $\frac{3}{4}$ stuff. Cherry or walnut is best, as the sun will not warp either, nor the rain swell them, so that the slides become immovable. The box is equally divided (crosswise) by a partition, which comes up even with the top of the box. Near the top of the partition, a hole $1\frac{1}{2}$ inches square is made, which may be closed by a slide that projects through the side of the box. For convenience we will call the apartments No. 1 and No. 2. Both have a sliding cover, similar to chalk-boxes. Each apartment has a slide. In No. 1 the slide is 2 inches above the bottom; but in No. 2, only 1 inch. Above the slide, in the end of No. 1, is a window, the size of a half-dollar, which may be darkened by a sliding cover. Near the end of the cover to No. 1 is a round hole, 1 inch in diameter, which may be closed by a slide fitted into the under side of the cover. In the cover to No. 2 is a window, the size of a silver dollar, with the glass fitted in the under side of the cover, so as to make the lower side perfectly smooth. This window may be darkened by a swinging slide which is fastened to the cover with a screw. In the end of No. 2, near the top, is a hole the size of a dime. This is also to be covered by a small swinging slide which should be screwed down tight enough to hold it in any position; for should it get loose we might lose the bees when carrying to another stand. This small hole is used when we wish to let out only one bee at a time. Beneath the slide in No. 2 should be kept a piece of comb about 4 inches square; and beneath the slide in No. 1 are kept vials of paint and brush for marking bees, and a cup and paddle for catching them. By using tacks in the inner ends of the slides, they may be kept from falling out of the box. We should also carry four or five extra pieces of comb.

For bee-feed, or bait, I use thin sugar syrup, when unpurified honey can not be had. Never use thick honey. Carry a good supply of bee-feed. I

use a pint bottle with a rubber-cork arrangement, from a beer-bottle, to carry the feed in (putting a bad thing to a good use, you know). A beginner had better go two or three miles away from tame bees; but an experienced hunter will have good success near large apiaries. Bees may be hunted any time when they can work. But the best time is when there is a scarcity of honey, or work for the bees only a part of the day, as during buck-wheat bloom. Start them early in the day; and as soon as the flowers cease secreting nectar, you will have plenty of bees at work.

Select a place where you will have a good chance for lining. Take all of the combs out of the box, except one in No. 2, which should be filled with the bee-feed; close the box; open the slide in the partition; uncover both windows, and open the slide to the entrance-hole in the cover to No. 1. Put feed in one of the extra combs, and place it beside the box; and somewhere on the stand stick a scented feather unless you are near an apiary. The bee-scent which I use is 12 parts oil of anise, 2 parts oil of rhodium, and 1 part oil of fireweed. I carry the feathers in a leather sheath. Never carry scented feathers or the bottle of scent in the bee-box; for should your combs get scented it is almost impossible to run wild bees near an apiary.

When catching bees I use a small pepper-box (without the cover), with an awl-hole through the bottom, and a little paddle about two inches by three. Catch the bee as it is gathering honey from a flower. It will immediately go toward the light which comes through the awl-hole. Place the paddle on the slide in the cover to No. 1, so as to slide the cup on to the cover over the entrance-hole. The bee will immediately go down into the box, if you darken the awl-hole with your finger, when the slide should be closed. Now darken the window to No. 1, and the bee will go toward the light in No. 2. As soon as it can be seen buzzing against the glass, close the opening in the partition, and darken the window. The bee will then settle on the comb and commence to feed. This operation may be done in less time than it takes to tell how. It will take the bee three or four minutes to fill. Meanwhile we can be catching other bees and leave them in either apartment.

The directions given in the A B C book for lining bees are good. But don't depend very much on the first lines. When they have made several trips, and have established a line of flight, they will usually go directly toward the tree. Note accurately the time when you let out the first bee, and when the first one comes back. From this you can form some idea of the distance to the tree. After you have the bees at work well, mark *one* bee with paint from one of the vials in the bee-box. Be careful not to daub the bee. The slightest touch is sufficient, and will remain on the bee several days. Then time the bee. You will need to watch the combs closely. Timing bees is a very important item in bee-hunting. Bees vary in their flight. But I have found that on an average they will fly a mile in five minutes, and spend about two minutes in the hive or tree. Of course, they will spend more time in a tree when they have to crawl a long distance to get to the brood-nest, hence we may deduce the rule: Subtract two from the number of minutes absent, and divide by ten. The quotient is the number of miles from the stand to the tree. (See GLEANINGS, 1887, page 431.) This applies to a

partially wooded country. Perhaps in a clearing they could make better time. On a very windy day it takes them longer to make trips.

Fremont, Mich.

W. E. GOULD.

(Concluded next issue.)

PREPARING BEE-CELLARS.

DO WE NEED TO GO TO MUCH PAINS AND EXPENSE
IN THE MATTER?

IT was with much interest that I read Dr. Miller's article on "Ventilating Bee-Cellars," in GLEANINGS for Aug. 15. By using a process of reasoning, he tries to establish something as a fact; but for all this the reasoning is so lacking in logic that scarcely any thing more than theory is brought out. This the doctor seems to realize; for he winds up by asking, "Where is the man who knows that ventilation for a bee-cellar is *not* needed?" Now, I feel a good deal as the doctor does when he says, "It is not very safe for me to be very positive about any thing that I think I know about bees;" nevertheless, as the doctor has given his reasons in support of "that I think I know," I wish to give my reasons for believing he is wrong, and answer his questions in the affirmative.

Eleven years ago I built my present bee-cellar, and, reasoning as Bro. Miller does, I provided for sub-ventilation in connection with direct ventilation from above. To make sure of plenty of pure air, I made these ventilators large, so that, with a brisk wind blowing, with the mercury at 10° above zero, outside, I could in one hour reduce the temperature inside from 45° down to the freezing-point, by throwing both wide open. After experimenting a spell along the line of rapid change of air, I became convinced that such was a positive injury to the bees, for the commotion caused did not subside for two or three days afterward. Without dwelling upon the items I will say that I was led step by step to where the sub-ventilator was left entirely closed, and the other, or direct upper ventilator, three-fourths so. In this way I wintered with fair success until my high-pressure experiment with the oil-stove, resulting in nearly a total loss, as the readers will all remember. Whether this loss occurred from too warm a temperature, or the gases from the oil-stove, I have never solved. It might have been from too much ventilation, as the ventilators were run nearly full blast all that winter. But, to return.

The next winter I resolved on no more artificial heat of any kind, and not to allow the temperature to go lower than 43°. I shut the upper ventilator (the sub-ventilator being filled up with two feet of dirt at the outer end) as tight as I could close it in all zero weather and below. Skipping over the minutiae I will say that, by degrees, I got so I left this upper ventilator closed for weeks at a time till last winter, when it was closed after the bees had been in the cellar for about two weeks, and left so till the bees were set out, and I never had bees winter as perfectly before. Of course, the bees got a little direct outside air every two weeks when I went in to see them; but as I must open and close four doors, inclosing three dead-air spaces, the direct fresh air that went in with me was very little indeed. This cellar is built on purpose for bees, in a side hill, and will hold 75 colonies, leaving me an alley-way, or 100

if packed solid full. I had about 50 colonies in it last winter. By keeping all ventilation shut off as above, the control of temperature was absolutely perfect. Three days of 10 to 20° below zero did not change the temperature inside one degree, nor did the same number of days with 60° above zero affect it more; while all through, the bees kept a perfect quiet, except as occasionally a colony broke the cluster to go after a new supply of honey. Twenty-five dollars would not have persuaded me to have those doors left open one single night during a warm spell, as brothers Miller and Root think so necessary. Friend Root, at the close of brother M.'s article, speaks of "trouble in cellar wintering." Unless I am mistaken, Mr. Root has never tried cellar wintering. It will not do to compare a bee-house above ground with a good bee-cellar. If it were bee-house or outdoor, I should say outdoor every time. From the above the doctor will see that I am "the man" to say that ventilation is *not* needed. Do I say that my cellar had no ventilation? No, I only say that it had *no special* ventilation. Listen:

Van Rittenkoff, who is the best of authority on this subject, says: "For every square yard of wall surface, at 9½° Fahr. difference of temperature, the spontaneous ventilation, or passage of air through the wall, amounts per hour to

4.7	cubic feet,	with walls of	sandstone.
6.5	"	"	" limestone.
7.9	"	"	" brick.
14.4	"	"	" mud."

Does the doctor now think that "doors wide open" are necessary? Again, P. H. Elwood, who is far ahead of the most of us apiarists regarding the science of ventilation, gives, if I understand him correctly, 200 colonies of bees as requiring less air than an ordinary man. Does not brother M. think he could get along with perfect ease, as far as air is concerned, in his bee-cellar all winter? I think I could in mine, built for only 75 to 100 colonies. Let us hear from others, as winter is near by, and we "want to know, you know."

Borodino, N. Y.

G. M. DOOLITTLE.

Now, old friend, you are wrong this time, and I am a little surprised, too, for you hardly ever make a mistake, even in regard to something that happened years ago. I wintered bees in the cellar, I think for three winters, and the last time they were so uneasy they made the cellar too warm. Besides, the smell of that cellar was decidedly unpleasant and uncomfortable. I tried to make the bees go back into their hives by ventilating, opening the doors and windows nights, etc., but I did not succeed. I think the bees in the cellar pretty much all died. One colony that I bought of a neighbor, and left outdoors, wintered nicely, just as my neighbor's bees did. The figures you give show how much air will get through the wall where no dirt is banked up on the outside; and where the soil is on Medina clay, and that pretty well soaked with water, I don't believe you get as much air as your table gives. I am very glad of these figures, however, for I have long been aware that both air and water pass through stone with more or less facility. It was after I had such bad success wintering in the cellar that I built my bee-house above ground, which I described at the time in the *American Bee Journal*.

COMB HONEY MADE BY MACHINERY.

THE END OF PROF. WILEY'S "SCIENTIFIC PLEAS-
ANTRY."

FRIEND Newman, of the *A. B. J.*, brings out a good point in the following remarks, which he gets off in one of his happiest veins of humor; and one who has heard him talk at our conventions will almost see him face to face while they read:

The "scientific pleasantries," which has made the name of Wiley so infamous throughout the world, and which was so greedily "caught up" and enlarged upon by sensational newspapers, with sundry variations to "spice up the story," has at last come to grief!

It ran like lightning! Factory after factory was built (in imagination), fitted up by special machinery to make the comb. But, alas! when cornered by a demand to point them out, the "loud-mouthed" prevaricators found it impossible to find even one!

When taunted with the offer of a thousand dollars to lead a committee of investigators to the spot where such a factory existed—lo, it had vanished out of sight!

Indaunted falsifiers said that such institutions were running day and night, filling fraudulent combs with glucose—but when pressed to name the number, street, and city—they failed to find any such place—even hundreds of dollars were tendered for a sight of such a place!

Then the runners who visit country merchants, gloated over the sensation and averred most positively that such honey-combs made of paraffine, filled with glucose, and sealed over by machinery, could be found on sale by the ton in Chicago. But when offered \$500 to conduct us to the place and witness the process, they were forced to acknowledge that they, too, had been duped by the Wiley lie, and that they had added variations to make a spicy sensation!

Lawyers, doctors, and even ministers were caught in the act of villifying an honest pursuit, having swallowed Wiley's "scientific pleasantries," without suspecting that it might be an un-scientific and unpleasant falsehood!

Nevertheless, the story ran like wild-fire—news-papers and correspondents added to it, to suit their fancy, and varied it to make it spicy, until the pursuit of bee-keeping was, like a bleeding lamb, sacrificed to their Moloch; and bee-keepers were derided and mocked when they attempted to deny the story and prove its falsity! But now that scientific pleasantries have been struck by lightning, exposing all its baseness, deformity, and falsehood—for

"Truth crushed to earth will rise again;
The eternal years of God are hers."

The sun, whose burning rays dried up vegetation and destroyed the honey-producing plants, and thus prevented the bees from gathering nectar from the flowers, has also scorched and dried up Wiley's lie, so that it will never more show its loathsome head!

The markets of the world are bereft of honey! The merchants' demands for nice honey in the comb are incessant. They advertise for it: write to apiarists for it, and offer "golden shekels" for it! Still there is not nearly enough to half supply the demand, even though the prices go up higher and higher every week!

Since writing the above paragraph, a honey merchant of Kansas City called at this office. He is scouring the country—east and west—to find nice honey in the comb, offering cash for it at the apiarists' doors.

Now, here for weeks and months has the "golden opportunity" been presented, as Mr. Dibbern puts it on page 584, "for these mythical factories to run night and day to supply the demand" for glucose in paraffine combs! Let them bring on the fraudulent article, "the combs of which are made by machinery, from paraffine, filled with glucose and sealed by hot irons!" Show up the beautiful stuff, which is such "a good imitation that only an expert can tell it from the genuine article gathered by the bees from nature's finest flowers!" Yes, exhibit the tons of it produced by "running the machinery night and day!" Now is the time for the frauds to show up! Forward! March to the front!

Dare any one say, that, if such machinery existed—if such manufactured "comb honey" were to be had—that it would not be forced upon the market in such quantities as to fill the present urgent demand? A rich harvest is here presented—but NOT A POUND of the bogus stuff is presented for sale at any price!—a confession that the so-called "scientific pleasantries" is a pernicious falsehood! a villainous, debasing, and diabolical lie which was struck by lightning and literally burned up by the fierce rays of old Sol at the same time that they destroyed the nectar of the flowers, and starved myriads of bees to death!

Ta ta "scientific pleasantries!"

Be gone, vile monster!

Thy sulphurous breath shall no more befoul that God-given, heaven-distilled sweetness—delicious honey!

AN A B C SCHOLAR'S SUCCESS.

A GOOD REPORT FOR 1887.

I MIGHT state at the outset, that I have been helped over the hard places by a careful perusal of your *A B C*, and the regular visits of *GLEANINGS*. I think it would not be discreet for me to go into all the details, as I am only an *A B C* scholar, but I will try to remember the advice of the editor of our church paper, which is, in substance, to study brevity in all communications.

In the spring of 1886 I sent a postal card to a bee-keeper a few miles from home, inquiring if he had any swarms to dispose of, and in a short time I received word that I could be accommodated. I drove over the first fine day, and, after inspecting the stock, bought two swarms (pure Italians). The bees knew fully as much about me as I knew about them; but I commenced to read, and soon became greatly interested in the little workers. Hearing so many reports of a discouraging nature from old-time bee-keepers, I concluded to run them for comb honey, and save buying an extractor. However, I managed to secure the encouraging surplus of about five pounds; but as they increased to six average swarms, amply provisioned for winter, I did not grumble. The next thing to consider then was the wintering problem. From what I had read and gleaned from different sources I was rather in favor of chaff hives, and on wet days and odd spells I made two. They are constructed on the single-story principle, with movable sides, etc., an ordinary Simplicity body being used for surplus. Cushions for the chaff hives were made out of the large sacks our binding-twine comes in. When filled with suitable chaff they answer very nicely. The two chaff hives were wintered on summer stands, with no protection from fences or shrubbery, having perhaps thirty pounds of honey each in September, 1886. I examined them April 1, 1887, and found them in good condition, and with nearly half their stores left. The other four I placed in the cellar Dec. 1, expecting the temperature to be over forty. As the polar waves crept around with icy breath, the thermometer went down almost to the freezing-point. I made up my mind the cellar was too cool, and that it was all up with the bees. I made a practice of going down cellar nearly every night, with a lamp, of course, as the cellar was as dark as midnight, poking my nose and ears up to the entrances, expecting they would succumb; but they weathered the blast and came out fair in the spring, with no signs of spring dwindling.

Now for the harvest of 1887. From my six

swarms, spring count, I have taken a little over 900 lbs. of honey, nearly all extracted, and increased to 16. Of that amount, the two chaff hives gave 440, leaving less than 500 for the cellar colonies. The best yield for a short term was 11 lbs. per day for five consecutive days from alsike. The largest surplus for the season was taken from a hybrid stock. One chaff hive contained a pure queen. The other was from a pure mother, but mated with a neighbor's blacks. On the 30th of June I had taken 130 lbs. from the Italian stock, and 127 lbs. from the hybrid stock, so you see it was nip and tuck between them, but the Italians swarmed first and got behind. I find a ready home market for what honey I have to dispose of, at ten cents per pound.

Nearly all my swarms require feeding. Since the basswood ceased to yield honey it has been very poor for the bees. Most of the queens have quit laying. Less than an acre of buckwheat kept brood-rearing booming through August. Goldenrod was very little good, owing to the extreme drought which still continues. W. H. TAYLOR.

Derryville, Ont., Can., Sept. 15, 1887.

CROSSNESS SOMETIMES A BORN TRAIT IN BEES.

SOMETHING FURTHER ABOUT THAT SPRING.

ON page 682, Ernest says: "Bees may be made cross by one of two ways; namely, robbing and rough handling." Yes, and bees are sometimes cross without any robbing or handling of any kind; they are born so.

I had a colony of bees once (I bought the queen of you) that stung people, chickens, dogs, and cats, if it they went within ten feet of the hive. It was during a good honey-yield, when robbing does not occur, and the bees had not been handled for, I suppose, at least six weeks. This was the colony that I tried carbolic acid on, and that stung me till my fingers swelled up as hard and stiff as hoe-handles. Some bees are like some children, naturally cross. If I were giving advice to a beginner who had cross bees, I would say, "Don't let them whip you out; stand over them and smoke them till they surrender. Bees that follow one around had better be killed, as recommended. The loss is nothing.

You say, on page 697, "I had not dared to ask God to send me a spring where there were no indications that there might be one; but in his loving kindness he had given us something we did not even ask for." Mr. Root, your account of the finding of the spring, your thankfulness, and all the uses you have made of it, read like a psalm. It is beautiful; but down deep in your inner consciousness, do you not know that that water had been stored up there for hundreds, perhaps thousands of years? And as you were not then in existence, how could it have been put there for you? I like to read those papers of yours; you have faith enough to almost move mountains, but of course you know that, when the wild Indian roamed over Medina Co., if there had come a drought, and he had been digging around with his hatchet, and had happened to strike the right place, the spring would have burst forth for him just as it did for you. MAHALA B. CHADDOCK.

Vermont, Ill., Sept. 21, 1887.

I declare, Mrs. Chaddock, I thought I had hit the nail on the head the last time. Well, I will try again. Bees may be made cross in

one of three ways—namely, robbing, rough handling, and, as Josh Billings says, a "bad borning." Now, if anybody else makes a suggestion, I just *won't* say that bees may be made cross in one of four ways.

Ernest has answered you in regard to the cross bees, but the part in regard to the spring is referred to me, of course. Why, bless your heart, my good friend, you are arguing on the same side of the question, and yet you don't seem to know it. To be sure, the water, as well as the coal and oil and gas, has been stored up in the ground for thousands of years, waiting for God's children to get it out; but are they any less God's gifts to his loved ones? We have neither time nor space to go into the doctrine of election and foreordination, but I think my reasoning is good. To put it the other way, God knows the future. He knew just what sort of a chap I would be, and, in accordance with it, placed these things where I would find them, even though he did it ages and ages ago; or, if you choose, put it another way, and say that in answer to my prayers, he impressed it on my mind to go and look in such and such places for his gifts. It does not make any difference to me what doctrine some of my friends hold. God answers my prayers, and fills my life with blessings like the spring and these other things I have told you of. But these are all treasures of this earth. On another page I have tried to tell you something about the treasures of the world to come.

REPORTS ENCOURAGING.

ENCOURAGING INDEED! I. R. GOOD'S FORTUNES HAVE CHANGED.

ABOUT one week ago, many of my bees were in a starving condition, the strongest having but a very little honey. Boneset and some of the early varieties of goldenrod were in full bloom, but there was not a drop of honey for the bees to gather. The wind was from the north, and the weather very cool. Several nights there was almost a frost. About that time I went up town and ordered some sugar for winter stores for my bees; but before I commenced feeding, the wind changed to the south, and the weather grew very warm. Yesterday it was 90° in the shade, and such a honey-flow as we have had for the last four days I never saw at this time of year. Many of my colonies have more honey already than they need for winter stores, and I am extremely happy. A few days more of favorable weather, and they will all have a great plenty to winter on, and Mrs. G. can take the sugar to make syrup for the babies. I shall get no surplus honey worth syeaking of, but up to date I have sold over \$600 worth of bees and queens, and I shall have about 40 more colonies to go into winter quarters than I started with in spring. Last year, nice comb honey went begging at from 8 to 10 cents per pound. Our merchants are now offering from 15 to 18 cents, but can't get any at even that price. I believe the scarcity of honey this year is a blessing in disguise to the bee-keepers. I. R. GOOD.

Nappanee, Ind., Sept. 5, 1887.

Bees are gathering honey at a good rate now from buckwheat, which is very plentiful here.

W. B. STEPHENS.

Stephens Mills, N. Y., Aug. 15, 1887.

I thought our season for honey was about over a week ago, but it has broken out afresh.

Beatrice, Neb., Sept. 6, 1887. J. R. CRAIG.

I have taken 300 pounds of comb honey from 5 colonies of bees, increased to 12, and sold 2. How is that for an A B C?

JOSEPH B. CLARK.

Cornwall Landing, N. Y., Aug. 4, 1887.

We have had four years' scarcity of honey, but this year is some better than the three years before this.

W. D. THARP.

Williamsburgh, N. C.

SOMETHING TO BE THANKFUL FOR.

Although the honey season has been almost a complete failure in this section, my bees have increased from 22 colonies, spring count, to 36 colonies, and have made me almost an average of 25 lbs. of comb honey to the colony, spring count, which makes me feel as though I can truly say that I have something to be thankful for, and feel as though I can be modeled to fit the business, and make it a successful occupation.

I. T. GOULD.

Corunna, Mich.

INCREASE A SUCCESS, BUT HONEY A FAILURE.

My experience this summer has been a perfect success in the accumulation of bees, but the honey crop was a failure. I went into the winter with 60 swarms in chaff hives. I lost 2 and sold 24, leaving 36 to commence the season. My first swarm came out June 3d, and I now have 88, besides losing a good many. For one week I could not control them. They had a mania for leaving. My experience was like M. E. Kimsey's, as stated in July 15th No. The bees would leave the hive, after staying three or four days, with considerable comb but no brood. What surplus honey I have had was from early young swarms.

J. DELAMATER.

Brooklyn, Mich.

BUCKWHEAT HONEY AND HONEY-DEW MIXED, FOR BEE-FEED.

The bees are booming here just now, and have been for some time, on honey-dew and buckwheat. I sowed about three acres of buckwheat the 15th of August, and it is in full blast now. If the frost stays off long enough it will make a crop of seed. I have a small patch that I sowed early that is well filled. I bought five swarms of bees the first of August at 25 cents a swarm. They were about to starve, and the man said he wasn't able to buy sugar to feed them. I fed them a few weeks and then they had lots of brood started, and are booming now. Do you think the bees will winter on the honey-dew they are gathering? It looks clear, like the buckwheat honey. May be they are mixing it. The honey-dew is only on the hickory-trees, for I can not find any on any other kind of tree. The drought has been severe here this season, and is not over yet, as far as water in the wells is concerned. The creeks and small streams are all dried up. Some have to haul water. I wish that man with so much "energy" could have been here this season to raise us some honey to eat with our buckwheat cakes this winter. We shall have to buy sorghum for a spread. I didn't get any honey this year, and

don't know of any one around here who did. I know of a dozen or more swarms of bees starving for my neighbors.

F. P. HISH.

Henton, Ills., Sept. 19, 1887.

Friend H., it is pretty hard to answer in regard to the safety of honey-dew for winter stores. A good many reports are to the effect that it is safe for winter, while a good many other reports would seem to indicate it unsafe. We shall have to bear in mind, however, that, while the former is positive, the latter is very uncertain, for it is extremely difficult to tell what killed the bees and what did not kill them. If honey-dew is comparatively clear, tastes well, and is nicely sealed over, I think I would risk it.

REPORTS DISCOURAGING.

AN OFF YEAR, BUT HONEY UP TO 20 CENTS.

THIS has been an off year in nearly every thing here. There has been no honey since white clover, and but little then. There is no fruit. Corn is hardly half a crop. There has been no rain for two months. The grass is all dried and burned up, and stock are suffering from lack of water. Comb honey is worth 20 cents at retail here, and none to be had at that. My bees have been in a starving condition since the last of white clover, and they would have starved had I not fed them. I commenced in the spring of 1886 with one weak colony of black bees in a box hive. I bought a select tested queen of you, and divided, making two, which I wintered successfully. From these two hives, spring count, I now have ten fair colonies, all in L. hives, with Italian queens, but it took work to do it. I am very anxious to winter all successfully.

O. T. HANSFORD.

Mt. Clare, W. Va., Sept. 12, 1887.

This has been the worst year I ever saw. W. T. Zink, of Junction City, Mo., was here a few days ago, and told me he had good strong colonies that had not a pound of honey in their brood-chamber, and would get no surplus at all.

S. S. LAWING.

Henderson, Mo.

DISCOURAGING FOR TEXAS.

You may put me in Reports Discouraging, for my hopes are not quite blasted, except for this year. I had 44 hives, spring count. I bought 25 empty double hives for the season, which cost me \$1.42 at home. I lost 6 colonies, and fed \$8.00 worth of sugar. About a third of my bees have no stores on hand. I have not taken a bit of honey this year. In some neighborhoods, bees have done tolerably well. The people will almost starve here, as there has been nothing raised to live on, on account of drought, which still prevails. I can only say, "God's will be done." I am trying to trust him for all, doing what my hands find to do. The two smokers came to Stringer and Roundtree. They still stick to the pledge. May God bless you and the Home of the Honey-Bees, and its inmates.

J. H. MORROW.

Dripping Springs, Hays Co., Texas.

NOT ONE DROP OF HONEY.

My bees have not furnished me one drop of honey this year; and the prospect now is that I shall have to feed all through the coming winter. I suppose I

shall have to go into Blasted Hopes, but it is the first time in 22 years. I can not blame my little pets, for it has been so dry here that it was impossible for the fall blooms to mature, and at this writing it is still dry. We had a very good white-clover crop; but for some unaccountable cause it did not secrete honey sufficient to keep the bees living.

Berthaville, Mo., Aug. 24, 1887. A. T. DOYLE.

"BUG-JUICE;" IS IT SAFE TO LET THE BEES WINTER ON IT?

For two months my bees have not made a living. I have bought sugar, and have part of them fed, but here comes a flow of bug-juice. I hardly know whether to call it a misfortune or a blessing. If they do not get too much they will use it before cold weather; but if it continues a week at the present rate they will fill their hives full. The honey is very thick, and tastes a little like bumble-bee honey. They are getting it off the willows. The twigs are almost black with bugs. They are on the chestnut, oak, and hickory. It does not taste like the honey-dew of 1884, but is a good deal better. It is so thick I could not extract it if I wanted to. I might remove the four center combs, put in empty ones, and feed sugar. What would you do?

WM. WITHROW.

Paint Valley, O., Sept. 19, 1887.

You would be on the safer side to remove the four center combs and feed syrup, though I am inclined to think the honey-dew you describe would be safe enough. While no doubt the bug-juice has been responsible for some of the winter losses, yet we have had several reports where bees have wintered very successfully on this honey-dew. See page 686, last issue.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

THE USE OF DIVISION-BOARDS.

I BOUGHT a one-story chaff hive of you this summer, but I did not get my bees in it until July 13th. I don't think they will quite fill the ten bottom frames. Would you advise me to take some of the outside frames out and use a chaff division-board on each side, such as you describe in your price list, or do you use them only in the Simplicity hive? If I use them, will the brood-frames need to be the same distance apart for wintering, and how many full ones will it require to winter them, without feeding this fall?

Huntsville, Pa., Aug. 22, 1887. W. H. HUDSON.

We use the chaff division-board on each side of the bees in the brood-chamber of chaff hives. In wintering, contract the brood-chamber by taking out the frames until there is just enough left to hold all the bees in the hive. For wintering, it is better to space the frames a little further apart than in summer; and be careful that they have enough feed in the frames you do leave in.

BEES AND FRUIT: THE ANTS AND NOT THE BEES THE GUILTY CULPRITS.

I notice in GLEANINGS, Sept. 1, page 662, that Mr. Berry is inclined to think the Italians will eat fruit worse than other bees; but I think it is just as you say—the bees could find nothing else, and it

was eat peaches or starve. I have Italian bees, and we had quite a crop of peaches this year, and I have never seen a bee on them. A great many of them were partly eaten by ants, thus giving the bees a chance to eat them. The bees have been gathering honey very fast the past two weeks. Friend Doolittle recommends preparing bees for winter the last of August or first of September. I have no doubt it is best in that locality to prepare thus early; but this month is generally the best we have for surplus honey, as we do not have much clover honey and no basswood.

Linn, Kan., Sept. 10, 1887. J. T. VANPETTEN.

Friend V., you will have to make allowances for difference in locality for all the teachings in GLEANINGS. Friend Doolittle is away up in York State, and you are away down south in Kansas. Of course, you can not make preparations for winter while the bees are storing honey. I think friend D. simply means this: As soon as it is probable that no more honey of any account will be gathered, make all necessary arrangements for wintering, in the way of stores and whatever else is needed.

MINERAL WOOL: QUESTIONS BY AN A B C SCHOLAR.

I am a member of your A B C class, but I can not find any answer to the following question: Would it be advisable to feed bees a little at the close of the fall honey-flow, so that they would be stimulated to cure and cap all of their unfinished honey-cells for winter use? I am a beginner in bee-keeping, and I have six colonies of Italians. The season has been so bad that I have scarcely any spring honey, and am dependent on buckwheat for winter supply, and that yields very poorly; for example, I have six colonies of bees within 500 yards of as fine a field of buckwheat as any one would wish to see (8 acres), and my bees have gathered hardly enough for winter use—not a pound of surplus. Have you tried mineral wool for packing hives to winter on summer stands? I intend to try it this winter. As it is indestructible, I imagine it can be used over and over again to good advantage.

F. SCHMIDT.

Millington, N. J., Sept. 16, 1887.

What you propose is exactly right. Feed the bees until they cap the cells over with nice sealed stores.—We have never tried mineral wool, but have had samples sent us. We have no doubt it would answer quite well. However, by reason of its expense and extra weight for packing material, we should very much prefer chaff. It is true, that mineral wool would never rot; but we have chaff hives in use now that were packed with chaff ten years ago, and we can not discover but that the packing is nearly if not quite as good now as when first put into the hives.

SUCCESSFUL IN SPITE OF THE SEASON.

The queen received of you in April has acquitted herself most splendidly, and the progeny of queens raised from her are fine yellow bees. We gave the queen and half-pound of bees three frames of brood, and have drawn on them frequently for brood since; still, through all the honey famine they have kept very strong, on very little feed. The season here was showery, and favorable until in July, when the drought set in. Still, there was no honey, and some hives were entirely destitute of stores. On the 13th

of August we had a bountiful rain, and the bees are now at work on the fall flowers, of which we have an abundance, so we hope for some surplus, as we labored to have our dish right side up. Twenty-three colonies in the spring we increased by artificial swarming to thirty-nine. There is a question we want to ask you or your readers: What is the probable cause of the disappearance of young laying queens that have been found to be laying, and apparently robust and healthy? We have lost five all together, some of them recently, after having been in the hive and laying all right for some time.

MRS. M. COLE.

My good friend Mrs. C., I don't know that I can answer your question about the disappearance of your laying queens. Two or three times I have noticed something like it, and was beginning to suspect there was some enemy gained access to the hives, that pitched directly for the queen; but as they stopped disappearing, the matter was dropped, and I thought no more about it.

ARE BEES LIABLE TO DIE AFTER A POOR HONEY SEASON?

I can not let this time slip without giving a warning note to bee-keepers on the wintering of bees for the following winter, on account of our protracted and extensive drought. Our hives are hardly as heavy as they were in the spring. Some are on the point of starving. My bees have had nothing since fruit blossomed, except a light run on basswood. They have about entirely quit raising young bees; and unless they are fed to induce late breeding there will be none but old bees to go into winter quarters, and consequently they will die by the wholesale. I remember nearly 20 years ago we had an extensive and very dry fall. That time my bees worked on white clover till July 20, but got nothing after that. Next spring, accounts from all parts of the country told of bees dying by wholesale. Some thought the honey was poisonous, as they nearly all had plenty of honey. Many complaints came from Ohio. Some of the old bee-keepers will remember it. That winter, of 41 colonies I lost all but one. Several years after that we had two dry falls in succession, in which I lost two-thirds of my stocks each year. Two of my neighbors lost their entire stocks. One lost 20, the other over 40 colonies, all by dwindling, all being alive when set out, and other years I have seen the same result from an absence of fall honey, though not so marked.

Rockton, Ill., Aug. 8, 1887. WILLIAM HOLLEY.

WIVES THE BEST JUDGES OF HOUSEHOLD CONVENIENCES.

I have a question to ask. Why don't husbands let their wives do their own planning? Now, do not think I want my husband to know nothing of my work or needs, for I know how pleasant an occasional surprise in the way of some new convenience about the house is. If it supplies a long-felt want it is doubly pleasant. To illustrate what I do mean, I will tell a true story. Four years ago, when our little daughter was a tiny girl of twenty months, and our sturdy son, who now turns the wringer for mamma on wash-days, was a wee baby of five months, our washings were heavy for me, and I often told husband I could not do them except for the wringer. This fact, and his desire to

make my work as easy as possible, prompted him to buy a washing-machine. I demurred a little, saying there were other things that I thought we needed more. He insisted that nothing was as necessary as preserving my health, and declared I was working too hard. As we had several workmen, this was true enough, and he ended by saying, "We will have the other things too." Although not convinced, I was silenced (doubtful if I would be now), and the machine was bought. It did help, especially when strong hands turned it; still, many times during the next year I thought if the ten dollars it cost had been placed in my hands to use as I chose for making my work easier it would have helped me more.

Moral.—If you can afford brussels carpets for the whole house, place the amount they would cost in your wife's hands, with the understanding it is to make her work as easy as possible, and it will do it, whether it buys carpets or not.

MRS. FLORA BEACH.

Corydon, Pa., Sept. 12, 1887.

My good friend, you have got Mrs. Root's ideas of this matter exactly; and she has had more than one washing-machine with exactly the result you mention. Almost all of them would do excellently, providing a good-sized man or boy is on hand to use it. In the absence of said commodity, the machine is soon set aside. Of late, every washer that has been presented has been accepted only on trial, and not one has found a permanent place in our home. In fact, every convenience that comes up is turned over to Mrs. Root, before we take hold of it at all; and with few exceptions she puts it exactly as you do: "The device is quite ingenious, and sometimes quite handy; but, my dear husband, I should very much rather have the same amount of money it costs, to buy something else with." Now, I have an opinion too, and a great many times I don't feel satisfied to have something that seems to me a wonderful household convenience turned off in that way; and I believe we come as near having family jars in this line, as we ever do. Of late, however, I wind up by saying, "All right; don't have it under any consideration, if you don't want it." But I do think it is every woman's privilege to have the money an article costs, in place of the article itself, whenever she wishes.

THE WAD OF BEES FROM A KING-BIRD'S CROP.

I am getting no honey this year so far, and I miss it greatly. I have not taken 50 lbs. yet. I never had bees in as good shape at the opening of the season. I have not taken as much honey from 86 colonies this year as I took from one last year. My crop last year was about 6000 lbs., but this season was too dry. We had no lack of flora. White clover bloomed profusely; basswood was as full as I ever saw it; but the continued drought did not permit the secretion of any honey. I trust it will have one good effect—that is, to clean up the surplus stock from last year's accumulation.

In regard to the king-bird's habits, my observations lead me to say that, after he has filled his crop with bees, he has the power to eject the "wad" from his mouth. I have picked up the bunch just as soon as dropped, which consisted of bees in a

compact dry mass of about the size of a large hazelnut. The juices were seemingly all extracted.

Duncan, Ill., Sept. 1, 1887.

W. H. GRAVES.

DOES THE HOT SUN PREVENT BEES FLYING AFTER NECTAR, AND SO REDUCE THE AVERAGE YIELD PER COLONY?

Does the hot sun prevent bees from going a long distance for pasturage? My reason for asking this question is, that, about two miles from my apiary, the bees did well, filling crate after crate with fine white comb honey, while my bees did not gather any at all, and some would have starved had I not fed them. The sun has been very hot this summer, so I concluded that bees could not fly in the hot sun any great distance, and return to their hives safely with a load of honey. I agree with you about foundation. I have a mill for making the flat-bottom foundation, but I shall order one of the other kind next year.

J. P. CALDWELL.

San Marcos, Texas, Aug. 24, 1887.

Friend C., I have sometimes thought that the bees seemed to think it was too hot to work, even when honey was to be had in the fields; but afterward I have had reason to conclude that honey was to be had only by very great toil, or that it was not to be had in paying quantities, except in the cool of the morning or toward evening. Many plants, like the spider plant and the Rocky-Mountain bee-plant, yield nectar only during the night; therefore when honey comes from such sources, the bees are necessarily idle during the heat of the day.

THAT FREE ADVERTISEMENT: A RARE CHANCE.

In looking over back numbers of GLEANINGS I find no answer to Mrs. Chaddock's advertisement. Now, I haven't the mule nor enough honey; but as you are so liberal with "ads." I should like to make an offer. Get one, two, three, or a dozen, to join with you. Pack in your Saratoga a few blankets, all your old clothes (none of your Sunday go to meetin's), plate, cup, and saucer (tin will do), knife, fork, coffee-pot, frying-pan, and some good coffee. A keg of butter and can of lard will not be out of place. Procure a small tent—a large one is not necessary. Come down here on the coast, and camp out; go fishing; go to the oyster-bar; roast and eat oysters; hunt shells on the beach; pull off your shoes, and wade in the surf. Wade in the water generally; fall down; get wet; get up, and go on as if nothing had happened; live out of doors; catch fish, oysters, clams, and you will go home next spring a new woman.

W. J. DRUMRIGHT.

Sarasota, Fla., Sept. 6, 1887.

Friend D., the picture you present is so exceedingly tempting that I am afraid there may be a good many besides Mrs. Chaddock who will take you up, and, of course, we shall come to you first to be initiated. If you mean we can gather oysters ourselves, and roast them on the shell, it would be a big temptation to at least one individual; for my memory does not cling to any dish ever invented for a hungry man that will compare with oysters from the sea-coast, served up in that manner. The getting wet, and going on as if nothing had happened, would suit me to a dot. My wife would soon protest, however, because of my undignified appearance.

THE HONEY BUSINESS.

Can a market always be found for all the honey a man can raise? What is an average yield for a hive, and what money will it bring per pound? What is the first cost of hive complete, including hives, bees, etc.? Is honey-raising a pretty safe thing to go into, or are there any great risks attending it? As clerking does not agree with me, I may have to go into the country, consequently I should like very much to hear from you, as I am much interested in the subject.

ALFRED FAGRET.

Baltimore, Md., Aug. 23, 1887.

Yes, sir, you can find a market for all the honey you can raise. The crop this year has been very light, and prices have come up considerably. There is demand for it all over the country now.—An average yield, per colony, of extracted honey, would be about 75 lbs. Of comb honey, about 50 lbs. The latter will bring from 12 to 20 cents, depending upon the quality. The former, from 10 to 15 cents. The business of honey-production has some risks attending it. The first and greatest is the danger of losing a large percentage of the colonies during winter. In ordinary seasons, with good care, the number of colonies lost during winter should be very small. Another drawback to the business is an occasional poor season, like the present one. I believe, however, that the honey business has no more risks or drawbacks than ordinary occupations. It is light work, and healthful. Moreover, it is an exceedingly interesting study.

CELL-BUILDING.

I have one colony of hybrids I don't understand. Some two weeks since, I began to stimulate them, as there was nothing for them to gather in the woods, and since that time I have cut out seven queen-cells, and they have three or four cells now. They have a nice young queen, only two years old, and as fine a lot of brood as you ever saw. Nor are they crowded for room. Some of the sheets of comb have nothing in them at all.

Veedersburg, Ind., Sept. 8, 1887. A. H. HEATH.

I should be inclined to believe that your stimulative feeding caused the bees to make preparations for swarming, as you said they were building queen-cells. It is possible the queen was defective in some way, and the bees were building cells with the view of superseding her.

GRAPEVINES AND CLOVER.

I have about one acre of land planted with Concord grapes, ten feet apart. I find the shade of the vine a great advantage to my bee-hives, of which I have 40 or 50. I am preparing to sow a bushel of alsike clover instead of red clover on my farm, with timothy. I have had no experience with grapevines and clover on the same land. Will they do together?

WM. CONNELL.

Davidson River, N. C., Aug. 2, 1887.

Friend C., if your vines are only ten feet apart you do not want any thing whatever occupying the ground between them. I am not an experienced grape-grower, but I think the clover would be as detrimental as so many weeds, and you certainly can not get a good crop of grapes from a weedy vineyard.

OUR QUESTION-BOX.

With Replies from our best Authorities on Bees.

All queries sent in for this department should be briefly stated, and free from any possible ambiguity. The question or questions should be written upon a separate slip of paper, and marked, "For our Question-Box."

Question No. 7.—Do you consider that the wintering problem is practically solved? If so, by what method—that is, in the cellar or on the summer stands? J. T. G.

Yes. In the cellar. DR. A. B. MASON.

I do not—in the North. C. C. MILLER.

I do. By use of a good cellar. A. J. COOK.

Yes, I think it is practically solved by both methods. O. O. POPPLETON.

Yes. In the cellar, north of the 42d parallel; outdoors south of it, in the Mississippi Valley. DADANT & SON.

Yes. A good cellar, well ventilated and kept at the proper temperature. MRS. L. HARRISON.

As we winter our bees on their summer stands without any preparation, I can not answer this question. PAUL L. VIALLO.

The proper food and temperature have solved it. Pure cane sugar is a proper food, and the proper temperature can be secured in a cellar. W. Z. HUTCHINSON.

No, not with me. I prefer to use both methods, that I may win somewhere, as does the man who follows mixed farming. Don't get all your eggs in one basket. G. M. DOOLITTLE.

I think the slate will have to be covered over on both sides several times more yet with the figures of that problem before it can honestly be called solved. Just now the hands are mostly up, snapping their fingers, and saying, "Teacher, please help me do this sum." The cellar seems to be a length ahead of the outdoor methods at present. E. E. HASTY.

No, not yet. From reports in the bee-papers, we read of losses every winter, both in doors and out. We winter all on summer stands. For outdoor wintering, give the bees a good windbreak, plenty of good honey, and a deep hive well packed with chaff, or its equal, and there is not much danger. We wintered over 40 last winter in quadruple L. hives, none less than 2 stories, and some of them 3; lost one colony. E. FRANCE.

I consider the problem of wintering bees with certainty completely solved; but as that solution requires capital and extra special manipulation. I do not consider the problem of *practically* wintering bees completely solved. I feel quite positive that the consumption of pollen, either in the form of bee-bread or floating in the honey during a period of continued confinement, is the cause of bee-diarrhea. JAMES HEDDON.

Let me try, friends. Let's see: how shall I word it? Well, I should say the wintering problem is pretty nearly solved by most of the old hands at the business; but notwithstanding this, I am rather expecting that our plans and theories will be most of

them upset by some exceptional winter that is liable to come at almost any time. I have faith, however, to feel pretty sure there are some among our number who will still come out all right, even through this exceptional winter that is somewhere in the future.

Question No. 8.—Is it advisable to arrange the hives in the apiary symmetrically, with reference to each other. What harm results from such arrangement? M.

I think it is. I don't believe any harm results, if the hives are put five or six feet apart. DR. A. B. MASON.

I think so. There is no harm, and room is economized, to say nothing of appearance. A. J. COOK.

Yes, I think so. By a little ingenuity there is no need of loss of queens during fertilization. G. M. DOOLITTLE.

I don't understand the question. We aim to arrange our hives so we can work them handily. E. FRANCE.

Not too much so, especially if they sit quite close together. Harm results mainly from loss of queens. JAMES HEDDON.

For the looks and convenience, it is advisable to do so. No harm results, if they are at least 3 feet apart. PAUL L. VIALLO.

No harm, if they have some trees or landmarks to guide them, and if the hives are painted of different colors. DADANT & SON.

For the convenience of the apiarist, I think it decidedly advisable; and if rightly done, I think no harm results. C. C. MILLER.

I know of no harm from such an arrangement, if hives are not too close together, while the advantages are many. O. O. POPPLETON.

I have almost always kept my bees systematically arranged in the apiary, 6 feet from center to center, hexagonally, and I think the advantages of speedy manipulation overbalance the disadvantages of confusion of bees by various causes. R. WILKIN.

The only harm is, that young queens are sometimes lost, and a returning swarm (when clipping the queen's wings is practiced) sometimes attempts to enter adjoining hives. If the newly hived swarm is left upon the old stand, and the old hive carried to a new location, let this new location be at the end of a row. If a swarm tries to enter the wrong hives, cover the hives with sheets. W. Z. HUTCHINSON.

There is a wise symmetry and there is also an unwise and damaging symmetry. The latter results in loss of queens, and in bees getting into the wrong hives. The former may be made to help against these very same evils. My theory is, that the apiary should be divided into a number of small groups. It requires no great genius to arrange a dozen hives so the form will help rather than hinder. This being done, place as many similar groups as you require, giving each group some locating object; as a big tree or a little tree, or an arbor, or a heap of rocks, or a grape-trellis. Put one group by the side of that little building, and another group on the other side of it; and so on till you have places

enough. Now number each place in the group, and also give each group a number, in some natural order, and you have the whole thing so you can carry it in your mind, and find or record any hive easily without having a number posted up at all. In your memorandum a hive is 5-3 or 11-8 or 13-6; the first number designating the group, and the second the position in the group. My practice is not quite equal to my preaching, as my groups stand rank and file, and do not have locating objects enough.

E. E. HASTY.

I believe I shall side in with friend Hasty; but if I am right, there has been hardly enough said in regard to having the hives differ enough in appearance. I am forced to believe that it is quite unfortunate that it is so expedient in many respects to have hives all exactly alike; and I have been wondering if it would not be well to say, have your hives exactly alike on the inside. Then let the outside show some portico, some Simplicity, some chaff hives, and may be some tenement hives, if the proprietor is not too much averse to the latter; then adopt the grouping plan and you are all right. Our apiary of 500 hives is, as you know, in groups of 7 pretty good-sized apiaries—the greater part of the 500; and at the angles are groups of 6 more, with a smaller number. See the picture of our apiary in the front part of the A B C book. In larger groups, bees do, however, make a good many blunders. While this does little harm in the way of queen-rearing, it probably does more or less harm in throwing two or three dozen bees into some hive not their own, every little while. I wonder if anybody can tell how much harm this latter really does do.

Question No. 9.—Which is cheaper and better in the long run—to purchase a comb-foundation mill and make foundation for your own use (providing you have 150 colonies), or to buy your foundation outright of a dealer?

L. J. W.

Purchase a mill, and make the foundation.

PAUL L. VIALON.

Make your own foundation, if you have that many bees.

O. O. POPPLETON.

Buy it. Who would think of getting machinery to make one buggy?

MRS. L. HARRISON.

I should suppose this would depend upon one's circumstances. From my small experience, I should say it is best to own the machine.

A. J. COOK.

Very much better and cheaper to own a mill or Given press, unless only starters are used in the supers, and no increase in the number of colonies.

DR. A. B. MASON.

I use Foster's molds, and like them much. With them a pound of wax can be worked as well as 50 lbs., and the cost of the machine is but a trifle.

G. M. DOOLITTLE.

It depends on your capacity for handling beeswax. Some apiarists succeed, others get so tired of the business that they sell their mill and buy their foundation.

DADANT & SON.

If you have your own help to work your wax, you had best buy a mill, if your dealer charges you more than 10 cts. per lb. over the value of wax.

R. WILKIN.

That depends. If your time is worth nothing at the time of making, perhaps it is better to buy a mill. If I could get a good price for sawing wood, I think I should rather buy the foundation.

C. C. MILLER.

We bought a 12-inch foundation-machine before we had 150 colonies. I am satisfied it is cheaper. We hire a good deal of help by the month. We make our foundation rainy days, when we have no employment for them at other work.

E. FRANCE.

Recent changes in the manufacture and use of comb foundation cause me to believe that it is better to purchase than to manufacture. I believe this branch of our business will pass into the hands of two or three specialists. Economy and comfort will demand it. Specialty has a myriad of advantages.

JAMES HEDDON.

I suspect that ten years hence some one will read over this question, and laugh merrily. Some of us laugh now. I use less than five dollar's worth of foundation in a year, and, of course, could not afford to run a mill, if it were given to me. I do not deny, however, that there are some apiaries where large amounts of foundation can be profitably used—notably where the honey all comes in one grand rush, and is stored by Italian bees.

E. E. HASTY.

It depends very much upon the man. The making of foundation has no connection with the practical management of an apiary; i. e., there is no reason why a bee-keeper should be a foundation-maker. The interest upon a machine and fixtures will pay freight on foundation, and the time spent in learning and making will nearly pay the profit. Foundation-making is a trade. Let us buy of those who by years of practice have learned how to make a good article. Most of the "fish-bone" in comb honey is the result of foundation bunglingly made by men who think they must have a mill, in the same sense that they have a honey-extractor.

W. Z. HUTCHINSON.

In addition to the reasons given above, I think it depends a good deal on whether the apiarist takes a notion to make his own foundation or not. If you take a notion that you want a nice patch of strawberries, you will have it, especially if the notion holds out. After you get it, and you take a notion you would rather raise strawberries than do any thing else you ever did in your life, you will be quite apt to make a strawberry-farm a paying business. When you get over the notion, the business will begin to run down. Now, this is true not only in bee culture, but in using machines. You can not make very much of a success at any thing unless you put your whole heart in it. Very likely, ten years hence (or may be a little longer) we shall laugh at the idea of one man trying to do so many things, just as we now laugh at the time when our country stores used to keep dry goods, groceries, drugs, books, and boots and shoes besides; and I confess there is much less care and worry, and oftentimes much more satisfaction, in concentrating all our energy on one line of work, and by this means furnishing a product superior to what the world has been in the habit of having.

BEE ENTOMOLOGY,

Or Enemies of Bees Among the Insect Tribe.

SOUTH CAROLINA BEE-STABBER.

INCLOSE a very accurate figure of a bee-deströying bug received from Mr. Swinson, Stateburg, South Carolina. The figure gives accurately the size, form, and markings. It is a very graceful, slender bug, and belongs to a very predaceous group. Their entire life's business seems to be to hunt out and destroy other insects. The scientific name is *Septoglossus phyllopus*, Linn. The specific name "phyllopus" is very appropriate, as it means leaf-like foot, and doubtless was given to this insect by the great Swedish naturalist because of the expanded posterior tibia. The general color is brown, or in some species nearly black. Right here I wish to praise Mr. Swinson's mode of sending insects. He sent several of all ages, each in a little hole by itself, and all in a long narrow pine block. I hope others will take pattern after him.

ANOTHER BEE-STABBER.

A beautiful pure white line extends across the wing-covers, as shown in the figure, which gives a ready means of identifying this bloodthirsty bug. The spines on the posterior femora and tibiae are also interesting. Say had this species from Florida, and described it as *albicinctus*, because of the characteristic white line. Glover says, this insect kills the destructive cabbage-bug at Evergreen, S. C. This cabbage-plant bug, *Strachia histrionica*, is very destructive, as well as quite beautiful. Thus we may conclude that this species that I am now describing does much good, and is well worthy our fostering care, unless it makes too free with the bees, which I hope will not be the case.

Our Southern bee-keepers will easily identify this insect by the white band and broad posterior legs. I am glad to get these, and all species of insects. I wish they would always come in such good shape as did these. Will Mr. Swinson report if he finds these bugs very destructive to his bees? I should not expect such to be the case.

A. J. COOK.

Agricultural College, Mich.

Prof. Cook:—I send you by this mail three or four insects, which I should like you to name. They catch and suck the life out of bees, flies, grasshoppers, etc. If convenient, please name through GLEANINGS.

ALVIN L. HEIM.

Chandler, Ind., Sept. 7, 1887.

Prof. Cook replies:

The insects sent by Alvin L. Heim, Chandler, Ind., are closely allied to the Missouri bee-killer, *Asilus missouriensis*. This is a species of *erax*, and is

smaller than *asilus*. By referring to my Manual, page 317, last edition, a figure of one of these fierce robber-flies will be found. They are reported from the Gulf States as more serious enemies of bees than are the dragon-flies, or bee-hawks, as they are called by bee-keepers.

A. J. COOK.

Agricultural College, Mich.

NOMADA BEES.

Mr. John Burr, Braceville, Ill., sends some beautiful bees of the genus *Nomada*, which he says drive the honey-bees from the sunflowers, and enter the hives of even the crossiest hybrids with no let or hindrance from the hive-bees. These bees were put up in nice shape, and came in fine trim. I am very glad to get wild bees, as I am working on this family, and want all there are in the United States.

These bees are very pretty and very numerous. They have long tongues, short hairs, and much resemble wasps. It is reported that these bees lay their eggs in the nests of other bees, and thus their young are cared for by another—a lazy trick; but until we human mortals cease to get that for which we pay no just equivalent, we must not berate these bees too soundly. They are known in England as "cuckoo bees," from this habit, as the cuckoo of Europe does the same thing—lays its eggs in the nests of other birds, as do our cow-buntings. I often tell children this story, and give my opinion of such a course. I say to them, "We ought all to hatch our own eggs." I wonder if the scent of these cuckoo bees, which is aromatic, does not serve to protect them, and thus enable them to pass safely into the nests of other bees, and possibly into the hive of the honey-bee. Thus it may not be fear that caused Mr. Burr's hybrids to permit their entrance. It was possibly an agreeable odor. "How wonderful are all God's works," and how little we yet know of the things close about us! Thus what an incentive we have to work and study.

Agricultural College, Mich.

A. J. COOK.

BEE BOTANY.

OR, HONEY-PLANTS TO BE NAMED.

ACTINOMERIS SQUARROSA.

MR. ROOT:—I send you a branch of a weed that grows here on our creek bottoms. Can you inform me what it is? It blooms during August and September; grows 5 or 6 feet high, and for a month or six weeks the bees are on it from morning till night.

This locality echoes the cry of nearly everywhere else, "No honey." We shall not get over 200 pounds from our 28 colonies, spring count. About one-half of them did not make a single pound of surplus.

HERBERT BRICKER.

Slate Lick, Pa., Sept. 16, 1887.

Our friends at the Experiment Station reply as follows:

A. I. ROOT:—The specimen you sent from Herbert Bricker is *Actinomeris squarrosa*, Nutt. This is one of our native weeds, often found in fence-rows and old fields, where it is usually troublesome.

EXPERIMENT STATION.

Columbus, Ohio, Sept. 20, 1887.

Per Craig.

Mr. A. I. ROOT:—Inclosed please find a specimen of weed that my bees are busily gathering honey

and pollen from, as I suppose. The weed is generally called horse-weed. I send it to you for the right name. Some stalks at the base will measure an inch or more in diameter, and will grow 6 feet high.

We have had so much dry weather that very many colonies of bees will be lost. JAMES A. STAFF.

Troy, Mo., Aug. 29, 1887.

MR. ROOT:—Can you give me the name of the inclosed plant? CHAS. OLIVER.

Conneautville, Pa., Aug. 28, 1887.

Replying to the above two letters, our friends at the Ohio University say:

The specimen you inclosed, from J. A. Staff, Troy, Mo., is *Ambrosia trifida*, L., horse-weed. The one from Chas. Oliver, Conneautville, Pa., is *Cirsium Virginianum*, Mx., thistle.

EXPERIMENT STATION.

Columbus, Ohio, Sept. 6, 1887.

Per Craig.

ANOTHER GOOD REPORT FOR 1887.

DOES ANYBODY NEED TO BUY A PATENT-RIGHT WHEN HE COMMENCES BEE-KEEPING?

OUR honey-flow was short and sweet. Last winter two-thirds of all the bees in old gums and boxes were killed off. Spring was a little late, but my bees were in fine trim for fruit-bloom, which amounts to some section honey with us, if properly managed in a good season. The fruit-bloom came, and was immense. Every twig was loaded with blossoms, and full of nectar. Bees worked at it two full days, and filled the brood-chamber fairly, when it began to rain, and continued to rain until the fruit and bloom were all ruined.

Next came the locust, which was again very full of nectar; but before the bees had a full start on them the same cold rain came again, and continued nearly two weeks, and the fields were covered with white clover by this time, but it was too cold for the honey to come. After the rain was over, and it got warmer, we got seven days on the white clover, and such a white-clover honey-shower I never witnessed before in this part of the State. Then the white clover was at an end, and since that time they have to work for a living. During that short flow I doubled my stock and secured 25 pounds of honey to each colony. The fall flow is dawning, and we look hopefully forward to that. We often secure a good flow from the asters, boneset, etc.

Don't you think, friend R., your statement is misleading when you say you know of no State, farm, or township right to a patent bee-hive that you would consider worth a copper? Those moth-trap patent-right peddlers just go after such bee-keepers as those who know it all, and who will not stoop to read GLEANINGS. Oh, no! They will pay \$20.00 for a moth-trap, then they proceed to catch moths, and sometimes they discover they are caught.

Mulberry, Pa., Aug. 21, 1887. L. W. LIGHTY.

I am sure, friend L., I do not know where in my statement is misleading in regard to buying a right to make a patent hive. May be the statement was pretty strong; but for all that, I think it pretty safe to err in that way. If somebody who was intending to go into bee culture were thinking of buying a patent-right, I would unhesitatingly say to him, "No, don't do it."

MYSELF AND MY NEIGHBORS.

Lay not up for yourselves treasures upon earth, where moth and rust doth corrupt, and where thieves break through and steal: but lay up for yourselves treasures in heaven, where neither moth nor rust doth corrupt, and where thieves do not break through nor steal.—MATT. 6: 19, 20.

SOME two or three weeks ago my eye happened to strike the text above, and it came home to me with wonderful force—"Lay not up for yourselves treasures upon earth." The question came to me, Is the inspiring purpose of my life to lay up treasures here on earth, or treasures in heaven? and it troubled me. I am working and planning, inventing and devising, day after day; in fact, I am never contented or at peace unless I am earnestly striving after something in the future. Now, am I really sure that this working and striving is for the kingdom of God and his righteousness? Supposing I succeed in my plans for making garden, secure wonderful crops by the use of fertilizers, irrigation, by the help of the windmill, thorough tilth, etc., what then? Why, then I shall be able to teach others, and it will give me pleasure to see them succeed in having something to do at home with their families. But what then? Well, I tried to reply to this voice that was interrogating me, that, in teaching bee culture, gardening, fish, and strawberries, I should also be able to teach godliness and purity. The latter is the plan I have had before me for many years; but I felt troubled, because I feared I was thinking too much of the treasures this earth can furnish, and not enough of the treasures in heaven, as we have it in our text. Earthly treasures give satisfaction where they are honestly acquired, especially if, in acquiring them, we help our neighbors. But there is another kind of satisfaction that is away beyond this. I am afraid I have not had it much of late. The things of this world have occupied my thoughts rather too much, and I have been reaping the fruits. And this reminded me that it had been some little time since I came into the factory before any one else was there in the morning, and prayed for all of our busy helpers. While these thoughts were in my mind one morning, a little before sunrise I went up into the office and sought the place I had gone to so much—the cloak-room adjoining the office. The special subject of my prayer that morning was, that God would tell me where to put my energies, and in what way to employ the restless activity which seems to be a gift from him. My petition ended something like this: "Lord, tell me what thou wouldst have me to do; and tell me if my work as I am doing it just now is acceptable in thy sight." As I rose up and went down to help the boys off with the market-wagon, there was the peace in my heart that I had felt many times before, after going to my Savior for counsel and advice. In fact, I expected the day would bring some sort of answer to my petition. The message came; and whom do you think the Savior selected to carry this message? In his infinite goodness it was in-

trusted to one of the boys with whom I have got acquainted through GLEANINGS. Yes, it was none other than a young "neighbor" of mine away off down in Florida. While he was perfectly well acquainted with me, I had no knowledge of his existence at all until the morning after that prayer. I was reading my mail as usual, when I found under the paper-weight of "General Matter" a single sheet of paper. On this sheet of paper were the following boyish words:

Dear Uncle Amos:—About a year ago last March father sent for GLEANINGS. I read it a little at first, reading about bees, but I had not any use for the religious part; but finally, after we had had it three or four months, I began to read *Our Homes*, and finally I read that the first thing, and last January they had it sent to me, together with a bound volume for 1885. I sent for *Our Homes*, Parts I. and II., and read them as soon as I got them. Reading your articles lead me to—what? Well, first to read other religious articles; and last Sunday to finally joining the church and showing the world I was going to try to be a Christian. Go on with your good work. You may get others interested; and may God bless you in it!

Last March you said you expected to visit Florida some time. Well, if you do, come and see us if possible. Can't you come this winter? We haven't any bees, but expect to have soon, as we are looking for some hives from you every day. But I have got some garden, "t'other side of that fence" (see p. 177). I have been very much interested in "What to Do," etc. I am the gardener here, and I guess you can imagine how I enjoy it, from my own experience. I haven't very much now, as I have been sick, and it is very dry; but as soon as it rains I am going to plant a big one for you to see when you come. Well, I have written more now than you will ever get time to read, so I will close.

ELMER KECK, age 17.

Bowling Green, Fla., Sept. 17, 1887.

May the Lord bless you, friend Elmer, for this little letter! And did you think, my boy, that Uncle Amos might ever get tired of reading such letters, or be too busy to take the time? Why, such testimony as you give makes me happier than I should be to receive thousands of dollars in the way of orders; and while I use the term "dollars" to make the comparison, I feel ashamed of myself; for treasures in heaven can not be compared at all with treasures on earth. The testimony you give indicates that, through my poor work, at least one of the boys in this wide, heedless, careless world has changed his mind in regard to religious things. It speaks, in fact, of the new birth that I was telling you about a short time ago. It tells that one of the boys who go to make up what we call "Young America" has turned his back on worldly temptations, and united himself with Christian people, and has started in the strait and narrow path from earth to heaven. The minute I read your letter it seemed to me as if the Master were saying, "Mr. Root, don't be troubled, even if you are spending a good deal of time and energy in the pursuit of bee culture, gardening, and other like industries, if, in so doing, you succeed in interesting the boys; and after they have got ac-

quainted with you through the medium of these rural pursuits, lead them to me and it will be time well spent." And, my dear young friend, I am satisfied now that it has been time well spent, although, very likely, I have oftentimes lost sight, somewhat, of the heavenly treasures in the perplexities and cares of this world. Dear child, I want you to pray for your Uncle Amos, that he may be still more useful in the field the Master has accorded him. And now I want to tell you that this little letter opens to me a greater and grander and wider field than ever I looked upon before. Very soon after reading your letter it occurred to me that, by using it for print as I have done, it might be an example to many other boys to follow in the path you have started in. The readers of GLEANINGS have looked on in surprise and wonder, somewhat, to see so many joining the ranks of those who promise to give up tobacco. It is true, that, as a slight inducement, I have offered the tobacco-users a little present by way of remembrance; but in this department, no earthly treasure will be needed. Those who take up the cross to follow Christ do not need any pay. The satisfaction of having done right, and the peace that he only can give, are not to be measured or compared or spoken of as we speak of earthly rewards; and, dear friend Elmer, please believe Uncle Amos when he tells you that you will have battles to fight. Yea, even the publication of this honest, simple little letter of yours may bring you persecution; but be not troubled nor afraid. In the same way they persecuted the great teacher Paul, and the prophets of old. If you have trials and difficulties, it simply indicates that you are in the army of the Lord. Keep your face steadfast toward the great Commander. Don't say any thing back to your persecutors, but tell Christ Jesus of your troubles, and you shall conquer, not only through life, but through death also; for did not the Master lead even grim death captive?

The part of your letter that pleases me most, my young friend, is where you say you have united with the church; and I am glad you did not tell us what denomination it was. It is some body of Christ's people near your home, and that is all we want to know. Now, tremblingly and prayerfully I ask the question, "Is there another soul among the readers of GLEANINGS that has been lately moved to give himself to the Master? or is there is a single one who will stand up as this young friend has done, and say that he wants to be a Christian?" If, through God's providence, GLEANINGS can be made the medium for receiving testimonials to strengthen and encourage others to enlist for the extension of God's kingdom, it will enter upon an era of usefulness that even I, with all the faith that many of you have given me credit for, have never yet dreamed of. Now, boys, what other one is there who has the courage to speak out and say, "I too am on the Lord's side"? What other one is there who wants to commence right *here* and *now* in laying up treasures in heaven, where moth and rust doth not corrupt, and where thieves do not break through nor steal?

TOBACCO COLUMN.

IS THIS DEPARTMENT MANAGED TOO LOOSELY?

I BELIEVE the tobacco question in GLEANINGS is becoming obsolete. For instance, in my case my little granddaughter conceived of a plan to get me a smoker, and so she wrote to you, and the smoker came. Now, the facts are these: I never used tobacco in my life, and you will see by her letter she did not say I would quit, but that I would never use it, and would throw all my influence against its use, which I always have and always will. In nearly all the letters the whole drift is to get a smoker, without money, and not from principle. They nearly all state, "If I ever use it again I will pay for the smoker," thus owning the object to be to get a smoker. Flora's object was to see if you could not be imposed upon. I told her if you sent me one I would pay for it. ELDER C. R. THOMAS.

Morrelton, Ark., Aug. 22, 1887.

My good friend T., you and your little granddaughter undertook to humbug Uncle Amos, and you got humbugged yourselves. Do you not see it? I remember the letter, and I remember thinking it was impossible that a little girl should undertake to deceive me, and so I sent the smoker, thinking I shouldn't lose by it, and I didn't. Very likely a good many are induced to come into this column because of the chances of getting a smoker for nothing. Well, I think it is better to give up tobacco in this way than not to give it up at all.

THE QUANTITY OF TOBACCO & JUICE THAT MAY COME FROM A CHEWER'S MOUTH IN 25 YEARS.

In looking over my old scrap-book the other day I came across a piece that I thought would be the very thing for the Tobacco Column of GLEANINGS. I hope you young boys who chew tobacco, and old ones too, will read this and think about it until you become disgusted with yourselves, and quit. The selection runs as follows:

THE FILTH THAT FROM A CHEWER'S MOUTH PROCEEDS.

Two ounces chewed a day, 'tis said to produce
A full half-pint of vile tobacco juice;
Which, if counted five and twenty years,
As from a calculation it appears,
With this vile stuff would near five hogheads fill;
Besides old quids a larger parcel still;
Nor am I with this calculation done,
He in that time has chewed full half a ton;
A wagon-load of that which would, of course,
Sicken a dog or even kill a horse.
Could he foresee but a single view
What he was in his life destined to chew,
And then the products of his work survey,
He would grow sick and throw his quid away.
Or could the lass, ere she had pledged to be
His loving wife, her future prospects see,
Could she but see that through his mouth would pass
In this short life, this dirty loathsome mass;
Would she consent to take his hand for life,
And, wedded to his filth, become his wife?
And if she would, say, where's that pretty miss
That envies her the lips she has to kiss?

Navasota, Texas.

F. I. SOMERFORD.

A GOOD LAW.

July 1, a law went into effect in Illinois that no one shall sell tobacco to boys under 16, without a written order from the parent. The world does move. Tally one for Illinois! C. C. MILLER.

Marengo, Ill.

After 20 years of tobacco filth, I gave up the habit 10 years ago. It is a great blessing to me to be rid of a filthy habit. Men worship tobacco; that is, it is their god, as you might call it. I do not think I am entitled to a smoker either. If a man has not

mind enough to control it, give him a smoker to assist him. He needs one, for it was the hardest task of my life. I think, "Poor weak man! I can't."

GEO. A. MATHEWS.

Katonah, N. Y., Aug. 28, 1887.

Gently, brother M. If it was the hardest task of *your* life, is it any thing strange that others with less decision of character have failed in the fierce battle? If it helps a man to have a reminder in the shape of a smoker constantly before him, by all means let him have it; and I don't believe it is best to call him weak-minded either.

Mr. E. Pearsy told me that he would quit the use of tobacco if you would send him a smoker. If he ever commences again I will pay for it.

SILAS THRAILKILL.

Barbers Mills, Ind., Aug. 11, 1887.

Please send me a smoker, if you think I am entitled to one, as I quit the use of tobacco three months ago, after using it ten years. I will pay you for it, if I ever commence its use again.

I. T. TALBOT.

Jonah, Williamson Co., Tex., Aug. 3, 1887.

My father has used tobacco for 25 years, and has now quit. He hasn't used any for four months. If he is entitled to a smoker, please send it. If he ever uses the weed again, I will send you the price of the smoker.

JESSE GUERNSEY.

Matherton, Ionia Co., Mich., Aug. 9, 1887.

OUR OWN APIARY.

CONDUCTED BY ERNEST R. ROOT.

FOUL BROOD. FEEDING, ETC.

AT the present writing, Sept. 27, we think we have the upper hand of foul brood. Ever since we began using carbolic acid, the disease has spread into no other new colonies; but we find it well nigh impossible to wipe out the disease entirely with acid alone, from the hives under treatment. From my present knowledge, phenol seems to be a success as an antiseptic; but as an eradicator in the colonies where foul brood actually exists, so far it is apparently a failure. From occasional reports in foreign journals, and from now and then letters which pass my eyes, my impressions, as above stated, seem to be verified. I say *impressions*, because I can not think it safe yet to dignify them as facts indisputable.

At the outset, I said we had the upper hand of foul brood. How, then, did we become master of the situation? As the modification of the Jones plan cured the disease, but did not prevent its spread in other colonies; and as carbolic acid apparently failed to wipe out the former infection, but was a good antiseptic, we combined our modification of the Jones plan with the treatment by acids. The *modus operandi* which seems to have cleaned foul brood from the apiary is this: After opening an infected colony we spray the bees thoroughly with a solution of carbolic acid, by means of our large atomizer, the solution being one part acid to 500 parts by weight of water. The old

hive is removed from its stand, and a clean one is substituted. The bees are then all shaken into the new home, and given frames of foundation. The diseased chaff hive is last of all taken away and boiled, in a manner which will be described in a future issue. Thus we not only cure the disease in the colonies themselves, but have prevented its spread into other hives. Most of the hives in our apiary have more or less healthy brood. If the disease were present in any of the hives, it would in all probability have shown itself ere this.

UNITING, AND PREPARING FOR WINTER.

In consequence of not being able to fill orders for bees by the pound, our colonies are very strong, so that we can not double up to the same extent we did last year. The total number of colonies which we shall put into winter quarters will be 250 when all are united—a somewhat larger number than last year, you will perceive. Not only that, but the individual colonies will be, in the majority of cases, double the strength of the average colonies of last year.

It was very difficult, in consequence of the robbers acting so badly, to unite during the day. We did a good deal of it in the evenings, but even then the robbers learned the trick of "staying out nights." Pretty soon the equinox came, accompanied by the usual rainy weather. "Now," said I to the boys one morning, as there was a light cold drizzle, "you will have a capital time for doing all the uniting you wish." The work which had been needing attention was now done with perfect ease. Pretty soon the drizzle turned into a light rain. Mr. Smith came in and said, "Do you think we had better open the hives now?"

"Oh, yes!" said I, "providing *you* can stand it."

I hunted up a rubber overcoat for Mr. Smith (Mr. Spafford having one already on).

When robbers are very bad during pleasant weather, and I am anxious to have preparations for getting the hives in proper winter shape complete, there is nothing that I welcome more than light rainy weather. With an old hat, rubber overcoat, and rubber boots, it is just fun to perform the operations which, during pleasant weather, are just out of the question, because of the persistence of the robbers. This morning, while feeding the bees, I was out during the light rain. What a pleasure it was to open the hives and pour in the feed, without a hundred or so of buzzing bees around! I could set the feeder-can down anywhere, and not be at all afraid that the little pesky thieves would have their noses in it.

Speaking of rubber boots reminds me that my light rubber boots which I mentioned in GLEANINGS last winter are good yet. They cost only \$1.75. They are very light, and are not so disposed to cause sweaty feet as the heavier ones.

WOODEN BUTTER-DISHES AS FEEDERS.

Some of our last-year's subscribers will remember that I gave my preference decidedly in favor of wooden feeders over those constructed of tin. During the cool months of last fall I found that bees would

take feed readily from the wooden feeder, when they would not notice one of tin. The past year I have been looking for some kind of wooden feeder that would be cheap, and yet answer every purpose. A few days since, a correspondent incidentally remarked in his letter, that he had been using wooden butter-dishes with good success.

"There," said I to myself, as I read that, "is just the feeder that I have been looking for."

Taking the letter in my hand I walked over to Mr. Calvert, our buyer, and showed it to him, putting my finger upon the paragraph mentioning the wooden butter-dishes. After he had read it I said, "See what you can do about getting wooden butter-dishes. I believe they would be just the thing, and the cost would be almost nothing. Why, a bee-keeper could afford to buy a couple of hundred of them; and when they were worn out he could burn them up and buy more."

Mr. Calvert, as you remember, wintered our bees successfully one year, and has had considerable to do with feeding. He saw the point at once, and set about immediately to see what he could do in the way of getting some cheap bee-feeders. In the course of a couple of weeks we had a consignment of wooden butter-dishes and—what do you think?—wooden pie-plates—the latter as neat and pretty in design as any thing you ever saw. The sides were scalloped, or corrugated, and the bottom was perfectly flat. It is hardly necessary for me to describe the wooden butter-dishes, as every one of our subscribers has no doubt bought a pound or so of butter in one of these receptacles.

They were left in the crate until rainy weather. Accordingly last night you might have seen me with a syrup-can in one hand and a pack of wooden butter-dishes and pie-plates in the other. I placed one of each kind in the hives I desired to feed; and then with the feeder-can I poured the syrup into one and then into the other. After both were filled I let the drip fall on to a few bees down in the cluster, that they might give notice of what there was above. After having filled all the feeders, I left them until next morning, without making any provision for floats, as I desired to see whether these shallow wooden dishes would require it. This morning I more than half expected to find a few bees drowned. Examination, however, showed that the feed had been licked up clean, and not a bee was seen in any of the feeders. As it continued to rain somewhat this morning, I refilled the wooden dishes, then watched the bees at one of the hives, as they greedily piled over each other, three or four bees high, to get at the feed on the edges of the dish. A few in their haste plunged over into the syrup. I stood holding the cover up, watching and waiting to see whether these bees would be able to get out. They swam along in the syrup; and when they reached the edges of the feeder they caught hold of the wood and shook themselves very much as a dog does when he first comes out of the river. Now, why is it that these wooden

dishes do not require feeder-floats as do tin pans? The answer seems to be this: In metallic receptacles, the bees, in the absence of a feeder-float, will swim to the edge; but on arriving there they are unable to catch hold of the metal. In the butter-dishes, on the contrary, a floating bee, as soon as his foot strikes the rough edges of the wood, the claw grasps the wood and he is safe. He has only to crawl among the bees, and he will be speedily cleaned of his "too much" feed. Another thing in favor of wooden butter-dishes and pie-plates is, that the sides are gently flaring. In an ordinary bread-pan, such as we used last year in feeding, the sides were quite steep, and we found that we were obliged in all cases to use cheese-cloth for a float for the bees, otherwise there would be large numbers of them drowned in the feeder. We have tried these wooden feeders now for three days, and we find scarcely a dead bee in any of them, even without any kind of float whatever.

THEIR COST, AS COMPARED WITH OTHER FEEDERS.

I presume the great majority of you will be able to purchase a few at your grocery store, just to try; but for those of you who are unable to obtain these wooden butter-dishes at your own home, and for those who perhaps would like to purchase 100 or 1000, we append the following prices: Wooden butter-dishes, to hold a pound of feed, $6\frac{1}{2} \times 9$, \$3.50 per 1000; per 100, 40 cts.; or 5 cts. for 10, by express or freight, with other goods. If wanted by mail, 12 cts. extra for 10. The wooden pie-plates, you probably can not obtain near you. We can furnish them for just double the price of the butter-dishes; postage per 10, 12 cts.

One can scarcely realize the cheapness of these feeders until he compares our lowest price for the Simplicity feeder in our price list. Price of these latter per 100 is \$2.50. Set this amount over against 40 cts. per 100 for the wooden butter-dishes, and then you can better understand their low cost.

Now a word in regard to these cheap feeders in comparison with other feeders. From what trial I have been able to give them, I think they work quite as well as the Simplicity trough feeder; though, however, if the price were the same I think I should prefer the Simplicity, as the latter occupies a little less room in the hive. But when we consider the difference in price, my preference would be very much in favor of the butter-dishes and pie-plates. The Simplicity wooden feeders, after a couple of years' use, become dirty, and sometimes soak through, and at times check so as to leak. The price of the butter-dishes is so extremely low that one can well afford to throw them away after one season's use, and use nice new clean feeders next year. Both the Simplicity and the butter-dishes hold one pound of syrup; so also do the pie-plates. These are very pretty, and will answer excellently, no doubt, for baking pies. You can take the pie-plate containing the pie to the picnic, and you won't have to fuss to bring it back; or you can send your pie to a church social, and it does not matter very

much whether the plate is ever returned or not.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER,
MEDINA, OHIO.

TERMS: \$1.00 PER YEAR, POSTPAID.

MEDINA, OCT. 1, 1887.

Thine, O Lord, is the greatness, and the power, and the glory, and the victory, and the majesty: for all that is in the heaven and in the earth is thine: thine is the kingdom, O Lord, and thou art exalted as head above all. 1. CHRON. 29: 11.

We have to-day, Oct. 1, 7649 subscribers.

GOOD NEWS FROM FATHER LANGSTROTH.

The following is just at hand, on a postal card:

Thanks to our heavenly Father, the dark cloud is all gone.
Dayton, O., Sept. 22. L. L. LANGSTROTH.

The "dark cloud" alluded to by our good friend is the brain trouble he has suffered from for so many years. We trust it will keep away long enough so we may be able to get something from him for our pages once more, if he feels equal to the task.

COMMERCIAL TERMS.

A GREAT many of our readers do not understand the meaning of certain commercial terms used in the quotations of honey. In reply to a number of inquiries, Mr. Muth makes the following explanation:

FRIEND ROOT: The expression, "on arrival," means that honey (like other goods) brings the stipulated price at wharf or depot here. It is the net price, no charges being made for hauling, storage, commission, etc. It does not mean that we will take, at that price, all the honey arrived at our wharves or depots. We buy all we want at the range of those prices, and have been liberally supplied by our friends, so far. "In the jobbing way" means the price honey brings when it passes out of the hands of the wholesaler into those of the retailer.
Cincinnati, Ohio, Sept. 20, 1887. CHAS. F. MUTH.

MERRYBANKS AND HIS NEIGHBOR.

THIS is a little book of 210 pages and 68 illustrations. The older readers of GLEANINGS will not need to be told what it is about. To our younger, or new readers, I will say that it is a book treating of bees (and hive-making), gardening, maple-sugar making, and other rural industries. It has also a good deal to say about our homes, and was written specially for the juvenile readers of GLEANINGS. More than all, it treats of one particular home that was started on a sandy foundation, but eventually became built on the rock Christ Jesus. The price of the book is 25 cts.; 10 copies, \$2.00; 100, \$18.00. If wanted by mail, add 3c each for postage.

THE HONEY-MARKET AT THE PRESENT DATE.

WELL, friends, we are getting some extracted honey at the prices offered in our last issue, so we shall not raise our offer any more just yet. And, by the way, it is quite interesting to look over the market-reports, to which we refer you on page 724. Please note what a great variation there is in prices. Our friends in St. Louis and some other points don't seem to have wakened up yet to the fact that honey is worth a great deal more money than it

was a few months ago. Yesterday, Sept. 28, I stepped into friend Kendel's, in Cleveland, and there was not a pound of honey to be seen, of any sort—good, bad, or indifferent. It looked a little funny, for the reason that I can not remember the time before in years back when there was not at least some sort of refuse or culled stock pushed back out of the way. It is now all sold out clean, and every pound is gone almost as soon as he gets it; and, in fact, I do not remember of seeing a single case of honey in the city of Cleveland.

QUEENLESSNESS IN OCTOBER—A CAUTION.

ALMOST every fall, when the weather begins to get cold, a great many of the younger ones order queens, saying their colonies have suddenly become queenless. The reason why they declare them to be queenless is because they can find neither eggs nor brood. Well, when we send them a new queen, they find it impossible, of course, to introduce her, and then they discover they had a queen already. Now, remember, friends, that, as a rule, you will find no eggs nor brood at this season of the year. While the weather is warm, and honey comes, the queen will often commence to lay, and a little brood may be seen in October and November; but these are the exceptions. After a rest of a month or two, however, brood-rearing generally commences, and is kept up more or less till spring; that is, where colonies are strong. We are glad to furnish you queens, but we don't like to see you waste your money uselessly; therefore remember, the absence of eggs and brood at this season is no evidence of queenlessness; and as the queens are small and insignificant looking now, if you are not careful you will not find them. If you can not find the queen, and feel troubled about it, give them a little unsealed brood from some other colony, in case you can find it to give them; and then if they start queen-cells you may be sure the queen is gone.

FRIENDLY RELATIONS BETWEEN THE EDITORS OF THE BEE-JOURNALS OF THE WORLD.

We are to-day, Sept. 29, honored by the presence of Mr. Ivar S. Young, editor of *Tidskrift for Biskjot-sel* (*Journal of Apiculture*), of Christiania, Norway. Brother Young is a big man in a good many ways. I do not know how much he weighs aivordupois, nor exactly how wide he is across his big broad shoulders; but I do know that he has a kindly and generous heart withal, and that he is wide and large and liberal in his views, and in his genial friendly good nature toward all humanity. A few hours ago we knew hardly enough about Norway to be able to say, without consulting a map, just where it is located; but his visit has opened our eyes to the fact that a great people, and a very friendly people, are across the water reading our bee-journals, and profiting by the improvements that are coming up so rapidly. What a responsibility rests upon the shoulders of the editors of our bee-journals! and what a grand thing it is for those who have been heretofore separated by thousands of miles, and great expanses of water, to talk face to face, compare notes, and exchange friendly and neighborly greetings! For myself, I begin to feel too small for the place I occupy: and many times, when I think of the great field before us, and these loving hearts ready to extend a friendly hand of greeting, that little prayer of mine comes up again involuntarily, "Lord, help!"

THE HONEY FROM TEXAS.

SOUTHERN HONEY IN GENERAL; HOW IT COMPARES WITH OUR BEST GRADES OF THE NORTH.

MR. ROOT:—I send you by express two sections of honey, representing the two grades of my crop. As Texas honey has no standing in the markets I want your opinion of this honey, fully expressed; and I especially want to know how these two pieces of honey compare with what is quoted as "white" and "dark" in the markets. As your decision will be of interest to your Texas subscribers, please answer through GLEANINGS.

J. S. WHITE.

Dodd City, Fannin Co., Texas, Sept. 16, 1887.

Friend W., I have examined carefully both sections. In appearance the dark section looks very much like our buckwheat honey; but for table use I should consider it rather inferior. In fact, if you didn't know it to be otherwise, I should say it was pretty near honey-dew. Such honey with us is very slow sale; but perhaps during this very dry season it might bring 10 or 12 cts. per pound. The other compares quite favorably with our nicest comb honey in appearance; but when we tested it on our supper-table, side by side with our clover and basswood honey, no one wanted it. At first taste it seems very fair; but there is an after-taste much resembling the horsemint honey that we had some years ago; and most of the Southern honey that I have got hold of is somewhat of this rank flavor. The looks would probably sell it; but if there were a considerable quantity of it I am afraid that customers would complain that it did not have the right sort of taste for honey looking so handsome. Just at present, while our basswood and clover honey brings from 18 to 20 cts., I think your best sample might sell for from 14 to 16 cts.

SPECIAL NOTICES.

RUBBER TIRES FOR CARPET-SWEEPERS.

MANY times, after a carpet-sweeper has been used for some time the tires on the wheel become worn or loose. We are prepared to furnish new rubber tires for Ladies' Friend and Gosben sweepers, at 10 cts. each, or 90 cts. per doz. By mail, 2 cts. each extra.

24-LB. DOUBLE-TIER SHIPPING-CASES.

OUR 24-lb. single-tier case has become so popular that the old-style double-tier case has rather gone to the background. Some, however, prefer a double-tier case. We have quite a large stock that we wish to close out; and to do so we offer them at the following low prices: Single case, in flat, no glass, 15 cts.; in lots of 10, \$1.25; 100, \$10.00. Glass for same, 8x13 $\frac{1}{2}$ in, in lots of 10 sheets, 60 cts. Per box of 64 sheets, \$2.50.

DISCOUNT ON GOODS BOUGHT THIS FALL FOR NEXT SEASON'S USE.

UNTIL further notice we will give a discount of ten per cent on goods strictly for next season's use, except the following: Machinery of all kinds for manufacturing; all tin and glass honey-receptacles; tin plate, and all counter goods. On Simplicity, portico, and chaff hives, we can give only five per cent. The principal goods included under the 10% discount are foundation, frames, sections, zinc, extractors, comb-foundation machines.

PRICE OF PASTEBOARD BOXES FOR 1-LB. SECTIONS
REDUCED.

We have succeeded in buying these 1-lb. section cartons so low that we are able to make a reduction in price of nearly one-third. We can now furnish them at 75 cts. per 100; \$6.00 per 1000, or \$55.00 for 10,000, no labels. See our adv't on cover, for further particulars.

TWENTY-FIVE GROSS OF BUCKEYE SASH-LOCKS.

SINCE we first began selling these locks we have disposed of thirty gross, because of their popularity. Just a few days ago we received 25 gross from the factory. By buying so many we are able to reduce the price in quantity a little. Prices are 5 cts. each; 50 cts. per doz., or \$4.00 per 100. By mail, 3 cts. each, or 30 cts. per doz. extra. Nickel-plated ones, one cent each more than above. For further particulars, see our adv't on the cover for Oct. 15.

CLOVER AND BASSWOOD EXTRACTED HONEY.

We have secured about 500 lbs. of last year's crop clover extracted honey, very nice, that we can sell, as soon as it arrives, at the following prices: In cases of 120 lbs., 12 cts. per lb.; 60 lbs., $1\frac{1}{2}$ cts. Less than 60 lbs., 14 cts. per lb., cans included. We have also secured some basswood extracted honey that we can sell at one cent below above prices. We still have some California honey at 4 cts. below above price of clover. We also have six 50-lb. iron-jacket cans of fall honey, almost equal to the California, that we offer at 7 cts. per lb.

MAPLE SYRUP.

We still have on hand in excellent condition a good deal of the syrup mentioned in this column last spring. Prices as follows: 1 gallon, \$1.10; 10 gallons, in 1-gallon cans, \$10.00; 5 gallons, in 5-gallon square can, \$5.00. As honey is so scarce, I presume this syrup will go off on short notice. We mail sample free on application. Our stock of maple sugar is very low at present, as we shipped nearly four tons to New York a few weeks ago. If any of our readers have any to dispose of, please let us hear from you, with samples.

A FOUR-COLOR LABEL, FOR ONLY 75 CTS. PER
THOUSAND.

Just think of it! we can furnish you a very neat four-color label, with your name and address, with the choice of having either "comb" or "extracted" before the word "honey," for only 75 cts. per thousand; 50 cts. per 500, or 30 cts. for 250, postpaid. The size of the label is $2\frac{1}{2}$ x 1 inch—just right to go round the neck of a bottle, to put on a section, or to adorn the front of a honey-tumbler. Send for our special label catalogue for samples of this and many other pretty designs in label work.

A FOLDING TUB-STAND.

THE adjoining cut shows a very handy contrivance for all those who use a wash-tub, and who do not possess a wringer and tub-stand combined. One of the advantages of this stand is, that it takes so little room when not in use. A great many use an old chair, that has lost its back, for a tub-stand; but when not in use, it is in the way, and not a very handsome object, while the one shown above folds up and is laid away till it is wanted again. This stand just fits a No. 1 size tub; and though so simple and light, it is so strong that it will stand firmly under almost any weight. The sticks are of ash. The price of the folding tub-stand is 25 cts. each; \$2.20 for 10, or \$20.00 per 100.

HORSE-POWER in Texas For Sale.

Nearly new, and all complete. To make a quick sale I will take \$25.00 for it. C. W. COSTELLO, 19tfd
Waterboro, York Co., Maine.

DADANT'S FOUNDATION FACTORY, WHOLESALE AND RETAIL. See advertisement in another column. 3tfd

DALY HAMMERLESS. DALY THREE BARREL.
MANHATTAN HAMMERLESS. PIEPER BREECH LOADERS.
Send for Catalogue of Specialties.
SCHOVERLING, DALY & GALES,
84 and 86 Chambers Street, New York.

BEE-KEEPERS, TAKE NOTICE.

I will, from now until Jan. 1, 1888, sell V-groove one-piece basswood sections, made on A. I. Root's new improved machinery, at the following prices: First-class, all white, at \$2.25 per 1000, and second-class at \$1.90 per 1000. Send a 2-cent stamp and get a sample of them. Address R. H. SCHMIDT, 19d
Caroline, Shawano Co., Wis.

TEN PER CENT reduction from regular prices for fdn. and Simp. bives in the flat, until Jan. 1, 1888.
E. C. LONG, Williamsville, Erie Co., N. Y.

FOLDING BOXES.

Our Cartons for enclosing Section Honey are the **best & lowest priced** in the market. Made in one piece. With or without Tape Handles. With Mica Fronts or without. In the Flat or set up. Printed or not. Any way to suit. We are bound to satisfy you. We have just put in special Machinery for their manufacture and are prepared to fill orders promptly. **Price List Free, Samples 5c.**
14 oz. Glass Jars \$5.25 per gross, including Corks & Labels. 11-2 & 2 gross in a Case. Catalogue of Honey Labels free.

A. O. CRAWFORD, S. Weymouth, Mass.

If you Wish to Obtain the Highest Price for Honey

**THIS SEASON,

CONVENTION NOTICES.

The Darke Co. Union Bee-Keepers' Society will hold its next meeting at Arcanum, O., on Friday, Oct. 28, 1887. J. A. ROE.

The Pan-Handle Bee-Keepers' Association will hold its next meeting Oct. 26 and 27, 1887, in the K. of P. Hall, No. 1138 Main St., Wheeling, W. Va. All bee keepers are invited. Blaine, O. W. L. KINSEY, Sec.

The North-American Bee-Keepers' Society and the North-western Bee-Keepers' Society will meet in joint convention at the Commercial Hotel, corner of Lake and Dearborn Streets, Chicago, on Wednesday, Thursday and Friday, Nov. 16, 17, and 18, 1887. Arrangements have been made with the hotel, for back room, one bed, two persons \$1.75 per day, each; front room, \$2.00 per day, each person. This date occurs during the second week of the Fat-Stock Show, when excursion rates will be very low. W. Z. HUTCHINSON.

HEADQUARTERS For Cards and Stationery for Bee-keepers and Others.

Besides our beautiful eight-color chromo card, we have other neat designs, also a fine selection of fancy address cards, for old and young, for business and amusement. Also two and three letter monograms, all at low prices. See Here, 50 fancy printed cards, 15 cts; 300 envelopes, 300 letter heads, printed, \$1. Package 25 assorted cards, 10 cts. Neat box of cards and honey candies, 15 cts. Circulars free. Address J. H. MARTIN, Hartford, N. Y. 20tfdb

CONVENTIONS.

DR. MILLER SUGGESTS SOME THINGS TO BE ATTENDED TO BEFORE WE CONVEENE.

I BELIEVE bee-conventions are increasing in popularity. Rightly conducted, there is no reason they should not. If I am not mistaken, in Germany they have a society, if not societies, with something like 500 members. Did any society in this country ever reach 200 members? Perhaps we have something to learn from our German brethren in this regard.

For many who attend the larger conventions, the attendant expense makes it important that every thing should be planned to occupy the time in the most profitable manner, and it appears to me quite worth while to spend considerable time in advance in talking the matter over. As one of the officers of the North-American society, I am quite anxious that our next meeting should be successful; and as the same things may apply to other societies, it is well to talk out loud.

Something has been said already about having the North American a representative society, but no definite action has been taken in that direction as yet. Perhaps it would be a good idea for those who have thought most about this matter, to tell us specifically just what should be done.

Going back to general principles, a mistake is often made in appointing the time—that is, the day of the week. If members are expected from a distance, and a two-days' session is to be held, Tuesday and Wednesday are by no means as good days as Wednesday and Thursday, nor even as Thursday and Friday. If the first day is Tuesday, it is difficult for some to be there on time; and if it

closes on Friday it is also difficult for them to get home in time; but it seems better, if there must be any break in numbers, that it should be at the last end rather than at the first. Besides, if a member is present and much interested, he will perhaps make more effort to remain than he would to get there on time.

One of the bad things about most meetings that I have ever attended is the being confined so many hours in a room with perhaps little or no ventilation, the attention kept continuously fixed for three or more hours at a stretch. It is a little strange that a set of men will get together and warmly discuss the kind of ventilation that is best for bees, and forget that ventilation is just as necessary for the human family. If it is difficult to properly ventilate the room, the windows can at least be opened during a 15-minutes' recess, when the members can be moving about without danger of taking cold. Neither is this recess a waste of time. I believe more can be accomplished in 1½ hours after recess in the forenoon or afternoon than in 1½ hours without a recess. I know I am rapping my own knuckles in saying this, but that does not alter the facts.

At what time should the election of officers take place? For one, I don't know. There seem objections to electing officers for the North American before the place of next meeting is decided; because, if it should be at the extreme South or North it might not be best to elect officers from the opposite extreme who might not be at the next meeting.

It has been customary for the newly elected officers to assume control during the latter half of the convention. There may be some good reasons for this, but there are some against it. A set of offi-

cers ought to be able to make more uniform work to act continuously through the convention than to begin at the middle of one convention and stop at the middle of the next. In other words, a change of officers during a convention makes more or less of a break. Considering that I am an officer in the North American, my suggestion may not seem a very modest one; but, in spite of the immodesty, the principle looks to me correct. I am quite willing, however, to let the old custom continue during the next convention.

On one point I feel a little hesitancy about speaking, but I believe I ought. It is quite common for a number of persons to attend the sessions of the conventions and pay no membership fees. It is, in general, those from no great distance. The man who has been to the expense of coming 100 or 1000 miles, and perhaps brings more to the convention than he takes away, pays his full share of all expenses, while others who have all the benefit of the discussions, and are at little or no expense in coming or going, absorb the whole with not even a "thank you." Bee-keepers are such a liberal set that their conventions have been made even more free than political conventions. Is it right? If you will ask the secretary or treasurer at any of our large meetings, you may be surprised to find how many dead-heads are present. I don't know just what is the best thing to do about it, but I think in some way every man should pay his fee on his first arrival.

C. C. MILLER.

Marango, Ill.

Thanks, friend M. I heartily indorse every point you make; and most especially do I indorse that matter of ventilating the room we meet in. When the room is poorly ventilated I get dull and blue, and am very apt to make up my mind that I won't come next time; whereas, if I can be near an open window I often get real happy, and wonder why it is I ever stayed away from a single national convention.—On some accounts I rather like our customary way of changing officers in the middle of the meeting. We are enabled to get somewhat acquainted with new comers.—This matter of each one paying his share of expenses is a difficult thing to manage, and I presume it always will be. Even in our churches it is customary for a limited number of the members to bear the heaviest burdens, and they are often those not very well off in this world's goods either. I don't believe I would ask each person to pay his dues on arrival, for it would be quite embarrassing to the class that are not in the habit of paying at all, and perhaps might cause some of them not to "arrive." If they want to come, and don't want to pay a membership fee, I should say, let them come. As you say, bee-keepers are whole-souled as a rule, and, as a rule, clever and liberal. Now, if we make too much fuss about this sad fact, that a great many come and participate in the meeting without paying their share of the running expenses, we might get the reputation of being close-fisted. I am glad you spoke about it in print, and may be this will stir a good many up to their sense of duty. I am very glad indeed that you are one of the officers, for then we shall be sure of your presence.

A CALL ON FRIEND JONES.

W. F. CLARKÉ GIVES US SOME GOOD NEWS.

ABOUT sixteen months had passed since my last visit to Beeton, which is some 70 miles distant from Guelph. Unexpectedly called to take a journey over the line of road which runs through Beeton, I gladly availed myself of the opportunity to stop over a train, and make a brief visit. The home apiary was the only one I had time to look at. It is in much better order than when I saw it last. High fences and neat trellises conceal it from the public street. Quite close to the business part of the village, it is yet retired and secluded. At the time of my last visit, Mr. Jones was busy removing evergreens from the woods, about six miles away, and planting them for a hedge. I predicted that it would be labor lost, for I have often tried to move such evergreens, three or four feet high, from the woods, but could never make them grow. They must be dug up when quite small, and first transplanted into a sort of nursery. A considerable percentage of them will die, and then your hedge can be made with the survivors. Nurserymen who raise them from seed, or import them from Europe when very small plants, move them three or four times before they attain a height of three feet, thus getting a ball of fibrous roots which insures their growth when finally transplanted to some permanent location. My experience leads me to the conclusion that it pays in the long run to buy evergreens of nurserymen, rather than go to the woods for them.

Three pleasant surprises met me this time at Beeton. The first was to find that our friend Jones had recently taken a decided stand religiously, having joined the Presbyterian church at its last communion season. I had noticed a considerable change in him from about the time that father Langstroth attended the Toronto convention, whence he accompanied Mr. Jones to Beeton, staying over Sabbath, and preaching. Other circumstances deepened the impressions then made. A Sabbath in Scotland, where Mrs. Jones's cousin is minister to a large congregation, was not without its effect. The Lord has an infinity of wise methods whereby he leads us to himself. What cause for thankfulness, if we are led to fall in with them, so as to find the *summum bonum* (the supreme good) of life! There are some others of our leading bee-keepers concerning whom it would rejoice my heart to be able to make a similar record.

This isn't bee-keeping, but it is something that lends a new fascination to every interesting human pursuit—gives nature fresh charms, brings peace and rest to the heart, and makes life worth living.

My second surprise was in the realm of apiculture, and connected with the theory of hibernation. In the course of some experiments for the cure of foul brood by the fasting method, Mr. Jones has demonstrated that bees can live without food for a considerable space of time. Three weeks is the longest period he has proved to be safe, but he is inclined to think that bees can fast longer than that without risk. I have no doubt that, in the winter cluster, they can go for a month without eating. Of course, this does not prove the fact of hibernation, but it harmonizes with the theory most completely, and naturally suggests a species of dormancy during long fasts. It would seem a wise

adaptation of nature and providence that insects, gifted with such intense activity during the working season, should undergo a change to fit them for long spells of rest during cold weather. If that change lulls their intense activity into comfortable repose, and so quiets down all their functions that digestion becomes a very slow process, and they need a meal only now and then, we have a wonderful and beautiful example of that harmony between the various forms of animated life and their environment, of which we see so much in other departments of nature.

My third surprise was created by an invention which will shortly cause a great commotion among the dry bones and not yet extinct fossils of bee-dom; for there are those who have virtually taken the position in regard to apiculture that the new is not true, and the true is not new. Nobody can invent any thing any more in connection with bee-keeping. What will these modern mummies think or say when I tell them that friend Jones has invented an appliance practicable with all movable-frame hives, from the old Langstroth to the new Heddon, which revolutionizes the manipulation of them, and will reduce the cost of comb-honey production at least twenty-five per cent? It is applicable to both open and closed-end frames, both to the brood and section departments of a hive; dispenses with tin strips and thumb-screws, prevents frames and sections being fastened with propolis, and is, by all odds, the best invertible, convertible, and change-placeable contrivance yet devised. By its use, you can turn over a hive in a twinkling if you wish to do so, and take it all apart with equal celerity; you can manipulate brood-chambers and section-cases at will, and do it all without rough disturbance of the bees. The crowning marvel of this new invention is, that it is ridiculously cheap, costing only a few cents. It is so simple that you are ready to wonder why every practical bee-keeper did not think of it at one and the same time, and you can hardly help laughing outright at the stupidity of the whole tribe, that not one of their number ever thought of it before. I know that all this will seem ridiculously extravagant to many, who will be ready to think I am easily carried away, and soon excited. Well, I have no ax to grind, except the ax of universal apiculture, so I can afford to be pooh-poohed, and I rather enjoy the fun of tormenting prejudiced unbelievers. To all such, let me say in conclusion, "LOOK OUT FOR THE LOCOMOTIVE WHEN THE BELL RINGS."

RUBBER GLOVES AS LIFE-PRESERVERS.

It is but the discharge of a benevolent obligation to the weak and suffering sisterhood of the race, that I give publicity to the good effects resulting from the use of rubber gloves by a lady afflicted with lung trouble. A daughter of mine was visiting a sister of her husband, in Michigan; and finding that she was injuriously affected by putting her hands alternately into hot and cold water in the course of her housework, it occurred to my daughter that perhaps rubber gloves would remedy the evil; so she wrote me to know where a pair could be got, and, as you know, I sent you an order for a pair to be forwarded. A note from my daughter, herewith inclosed, narrates the sequel.

Guelph, Ont., Can., Oct. 6, 1887. W. F. CLARKE.

My Dear Father:—Mrs. Cossar writes: "Those rubber gloves are proving perfect blessings to me. The cold has gone from my throat and bronchial tubes,

and the pain and oppression from my lung; thanks to you for the prompt gift of these handsome tan-colored life-preservers." You see she has so much napkin-washing and dishwashing to do again, and the change of temperature of the water affected her lung trouble. I have an idea I should like a pair myself, if the duty would not be so much that the price would spoil the pleasure of using them.

Hamilton, Ont., Sept. 19, 1887.

ALICE.
